CIRRHOSIS OF THE LIVER TREATED WITH PROLONGED SODIUM RESTRICTIONS

IMPROVEMENT IN NUTRITION, HEPATIC FUNCTION, AND PORTAL HYPERTENSION

Charles S. Davidson, M.D., Boston

Cirrhosis of the liver is characteristically associated with a moderate or a severe degree of undernutrition that is evidenced by wasting of muscle mass and loss of subcutaneous tissue. Massive ascites usually accompanies this state of chronic, severe liver disease, so that the patient with cirrhosis and massive ascites has been likened to a spider because of his large fluid-filled abdomen and spindly extremities. That this state of undernutrition in cirrhosis is often reversible was shown particularly by the classic work of Patek and his colleagues.[1] The complications of liver disease, such as massive hematemesis, hepatic coma, and, of more particular concern here, ascites requiring frequent paracenteses, has limited the effectiveness and possible duration of nutritional therapy, thus shortening the time available to permit improvement in nutrition and, presumably, in the liver disease.

Work from a number of clinics has demonstrated that sodium restriction when continuous and of sufficient degree will effectively control ascites formation and will sometimes lead to prompt diuresis and loss of fluid accumulation.[2] Many patients, however, do not have a prompt diuresis and loss of ascites when such a regimen is instituted but continue to have ascites although paracentesis is no longer required. My purpose is to present here the sequence of events of 30 patients with chronic cirrhosis of the liver and with ascites and edema, most of whom were undernourished and who were treated with an adequate diet restricted to approximately 200 mg. of sodium per day for periods of from a few weeks to two years. Evidence will be presented indicating that, with suitable cooperation of the patient and barring other complications, such a regimen, if persisted in, leads to loss of ascites and edema, improvement of the nutrition of the individual, and evidences of amelioration of the liver disease and portal hypertension.

MATERIALS AND METHODS

The 30 patients discussed were selected from the medical wards of the Boston City Hospital because of a diagnosis of cirrhosis of the liver with ascites and on the basis of a presumed ability to cooperate with the regimen prescribed. None was suffering at the time from other complications of liver disease. Of the 30 patients, 28 were known chronic alcoholics, but 2 clearly were not, although the cause of their disease was unknown. All patients were transferred to the metabolic ward in the Thorndike Memorial Laboratory for study except for three for whom the regimen was instituted on an outpatient basis. The patients admitted to the ward for study were followed for periods of from a few weeks to many months and subsequently were discharged to the outpatient clinic, where the regimen was continued. The diagnosis of cirrhosis of the liver was made on clinical grounds and was substantiated by biopsy or autopsy in several instances. Four of the patients were considered well nourished when first observed. In 16, undernutrition was moderate, and 10 were severely undernourished.

All patients studied on the metabolic ward were provided with a diet adequate in calories and protein (50-100 gm. daily) but containing approximately 200 mg.

From the Thorndike Memorial Laboratory, second and fourth medical services (Harvard), Boston City Hospital, and the Department of Medicine, Harvard Medical School.

This work was done under the sponsorship of the Commission on Liver Disease, Armed Forces Epidemiological Board, and was supported in part by the Office of the Surgeon General, Department of the Army, in part by a grant from Merck & Co., Inc., Rahway, N. J., and in part by a grant from Lederle Laboratories, Pearl River, N. Y., to Harvard University.

This work was begun in collaboration with Drs. A. M. Cooper, W. W. Faloon, and R. D. Eckhardt[2] and has continued with Drs. G. J. Gabuzda Jr. and H. S. Traeger.[2d]

of sodium daily. The diet used was that previously described,[3] with minor modifications. Essential for sodium restriction of this degree is a low-sodium milk product. We have used Lonalac with good success. Calculation of sodium content was made from published tables.[4] While the patients were under study on the ward, the dietitians availed themselves of the opportunity to teach them how sodium restriction could be maintained when they were discharged to the outpatient clinic.

The control of ascites formation by sodium restriction was shown by a constant weight and abdominal circumference and a relatively steady daily urine volume. When diuresis was rapid, body weight and abdomin circumference decreased and the urine volume in creased. Slow diuresis usually was not reflected by pe ceptible change in urine volume, and weight loss wa often masked by a concomitant gain in flesh. Method used for laboratory determinations were standard c have been previously described.[5] Diets were occasionall analyzed for sodium, potassium, and nitrogen; the elec trolytes were studied, after ashing, by flame photom etry and the nitrogen was studied by macro-Kjeldah analysis.

RESULTS

The response of the patients to the adequate die restricted in sodium described above was of three kind (table 1): prompt diuresis, delayed diuresis (loss o ascites and edema only after prolonged sodium restriction), or failure. Diuresis began within a few days afte

sodium restriction was instituted in four patients (group 1) and continued until each was free of ascites and edema (fig. 1). Fourteen patients (group 2) were maintained with ascites and edema but without paracentesis for from 3 to 16 months by sodium restriction. During this time gradual loss of ascites and edema became evident and was usually attended by a striking improvement in nutritional status (table 2 and fig. 2, 3, and 4). Several patients required many months of sodium restriction before ascites disappeared. Improvement in liver function and a rise in serum albumin concentration were also frequently noted (table 2). The menses often reappeared as this improvement became evident, and the males usually noted an increase in libido and in body hair. Perspiration, usually greatly diminished when ascites is present, was often noted to return at about the same time. Evidences of portal hypertension were often seen to diminish: loss of ascites, decrease in visible abdominal collaterals, and reduction of splenomegaly (fig. 3, left two pictures, and fig. 4).

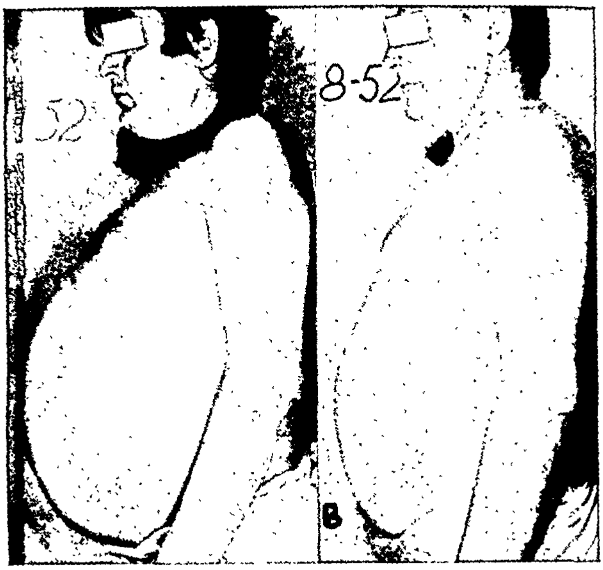

Fig. 1.—Prompt, continual but gradual loss of ascites from an alcoholic with cirrhosis of the liver. Other changes in habitus may be noted. *A*, April 11, 1952; *B*, July 8, 1952. Treatment was an adequate diet with about 200 mg. of sodium daily, after alcohol withdrawal.

* B = before, A = after sodium restriction. For duration, see table 1.
† G = good, F = fair, P = poor.

Twelve patients (group 3) failed to lose ascites and edema, although ascites formation ceased in every case. All but one of these had an inadequate trial of sodium restriction, due either to failure to adhere to the regimen, often with resumption of drinking, or, in two, to death from massive upper gastrointestinal hemorrhage.

Of the patients in whom a diuresis occurred, four have subsequently died (three of hepatic coma and one of gastrointestinal hemorrhage), five have been lost from the clinic, three of whom are known to be ascites-free although drinking again, and six are well. Ten of the patients who lost ascites and edema were allowed a moderate sodium intake (usually between 1 and 3 gm. of sodium daily) after diuresis had been completed and were found to be able to excrete these sodium loads normally.

Laboratory determinations when they were done both before and after sodium restriction and diuresis indicated improvement in each instance. When bilirubinemia was present, the concentration usually returned to normal or at least showed considerable improvement. Some reduction in sulfobromophthalein retention was likewise noted in most instances in which the test was done on both occasions.

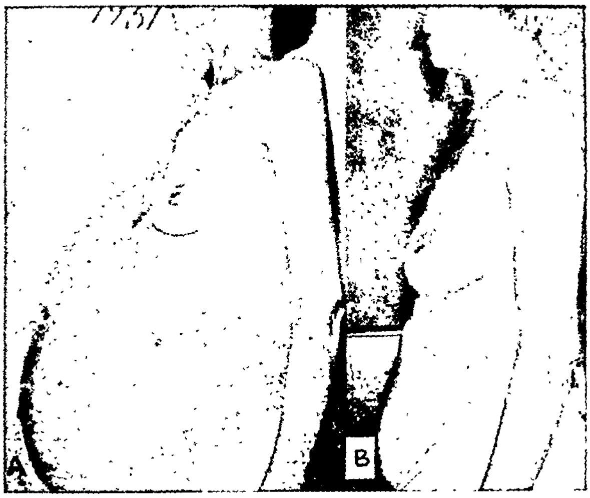

Fig. 2.—Gradual loss of ascites and marked improvement in nutritional status of patient with cirrhosis of the liver. Disappearance of abdominal collaterals is evident. Treatment was an adequate diet with about 200 mg. of sodium daily, after alcohol withdrawal. *A*, photograph taken April 5, 1951; *B*, taken March 21, 1952.

The serum sodium concentration was 135 mEq. per liter or below in six of the patients and during sodium restriction rose to 135 mEq. per liter or above. In every patient in whom diuresis occurred, the initial serum albumin concentration was 3 gm. per 100 cc. or below, and in each of the 11 instances in which the measurement was made on both occasions, the concentration rose, reaching 4 gm. per 100 cc. or above in 3.

COMMENT

The results indicate that sodium restriction to approximately 200 mg. per day controlled ascites and edema formation in all of the 30 patients with chronic cirrhosis of the liver. This confirms our previous experience with this regimen and that of others. Prompt diuresis, however, was observed in only 4 (group 1) of the 30 patients, so that this favorable response can seldom be expected. It was necessary to continue sodium restriction for from 3 to 16 months until the remainder of the patients studied long enough were ascites-free. Six months or more was required in nine of the patients. The restriction of sodium intake was continued after the patients were ascites-free in almost every instance, sometimes for many months. After this, all nine of the patients to whom a moderate sodium challenge was administered were able to excrete the load, maintain sodium balance, and continue to be free of ascites. Presumably strict sodium restriction was unnecessary after ascites disappeared in the patients in whom it was continued; however, it was considered better not to alter the regimen too rapidly, particularly early in the study before the rapid regaining of sodium tolerance was realized. Usually liberalization of sodium intake was begun by increasing the meat allowance for the day. If this were well tolerated, regular milk was substituted for the sodium restricted milk product. Then regular bread and salted butter were allowed. Most of the patients continued not to use salt at the table and avoided highly salted foods.

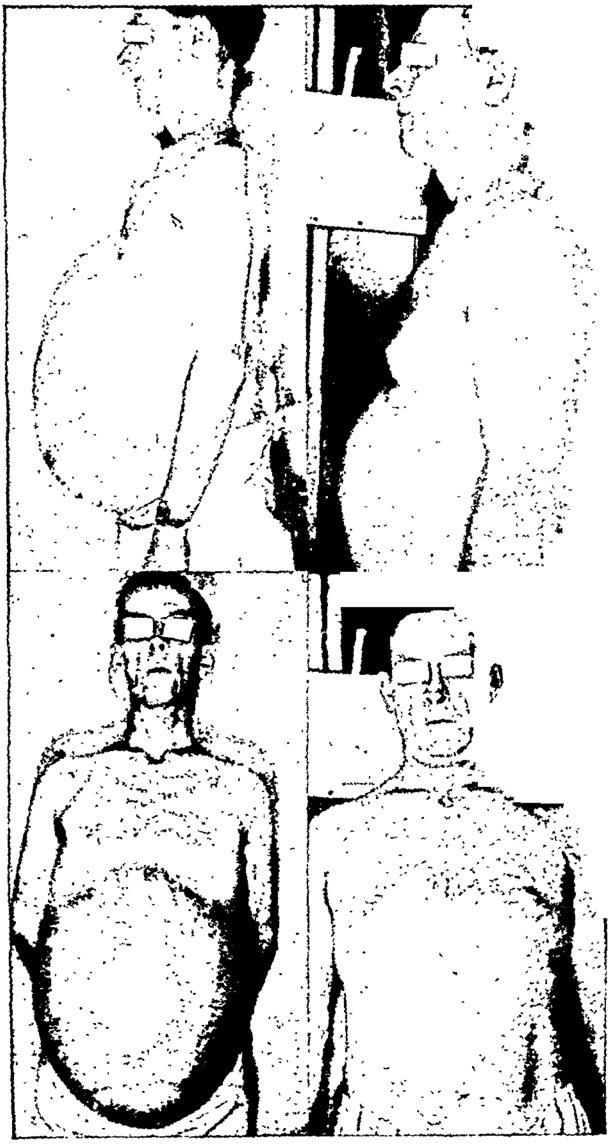

Fig. 3.—Gradual loss of ascites and marked improvement in nutritional status of patient with cirrhosis of the liver. Disappearance of abdominal collaterals is evident. First picture was taken Dec. 24, 1951, and last, Aug. 20, 1954. Treatment was an adequate diet with about 200 mg. of sodium daily, after alcohol withdrawal.

The improvement in nutritional status experienced by most of these patients was striking and usually coincided with evidences of improved liver function (see below), increased feeling of well being, and improved appetite. It was not possible to determine which of these changes came first. The results demonstrate that relatively severe sodium restriction even when prolonged and necessitating the use of a sodium-restricted milk is compatible not only with maintenance of adequate nutrition but also with a gain in body flesh and fat.

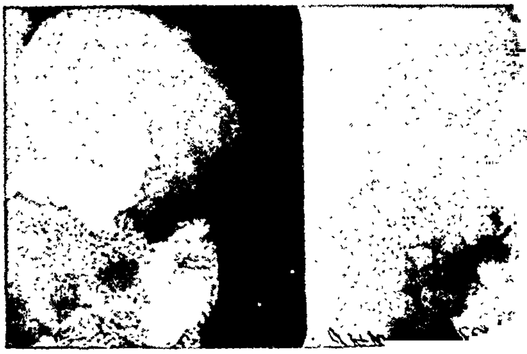

Fig. 4.—Roentgenogram of patient shown in figure 3. X-ray examination with barium shows the stomach pushed to the right by large spleen before therapy (left). Considerable shrinking of the spleen with movement of stomach to more nearly normal position is shown on right.

The improvement in serum bilirubin concentration, sulfobromophthalein excretion, and serum albumin concentration, together with the return of menses, increase in libido and in body hair in the males, and the return of perspiration, strongly suggest that continuance of the adequate diet with sodium restriction permitted improvement in liver function, presumably from liver regeneration.

Although it is possible to maintain patients with cirrhosis of the liver in positive nitrogen balance even when the disease is advanced, the positiveness of the balance usually increases as evidences of disease diminish.[6] Precisely how severe liver disease interferes with the laying down of body tissue protein is not known, although several disturbances in amino acid metabolism have been demonstrated. Increased urinary excretion of amino acids, although often present in patients with severe liver disease, is not great enough in extent to be limiting nutritionally. Improvement in absorption of protein likewise is not a factor, as stool nitrogen is not particularly increased in these patients.[6]

[6] Gabuzda, G. J., Jr., and Davidson, C. S.: Protein Metabolism in Patients with Cirrhosis of the Liver, Ann. New York Acad. Sc. 57: 776-785, 1954.

It is clear that the 12 instances of failure were due to incomplete follow-up, to failure of the patient to cooperate with sodium restriction after discharge from the hospital, to return to alcoholism, or to death from massive upper gastrointestinal hemorrhage or hepatic coma. Of the patients who sustained a diuresis, four have returned to alcoholism again; one died of hematemesis and three of hepatic coma, one after morphine administration; one developed a psychosis of unknown etiology; and four were subsequently lost from the series. Thus, only six remain well. It is evident from these results that, although ascites and edema can be satisfactorily controlled and as liver function improves the fluid accumulation disappears and the patient returns toward a more normal existence, the problems of chronic alcoholism and hepatic coma become the limiting factors in recovery and rehabilitation from cirrhosis of the liver.

The decrease in portal hypertension observed here might be considered to obviate the necessity for accomplishing this result by surgical means (e. g., portacaval shunt). However, to establish this concept firmly it will be necessary to show that esophageal varices disappear and do not bleed during treatment or after.

SUMMARY

The provision of an adequate but sodium-restricted (200 mg. daily) diet prevented the further accumulation of ascites of 30 patients with cirrhosis of the liver. Prompt diuresis occurred in 4 patients but was delayed (3 to 16 months) for 14 and failed to occur in 12. Prolonged therapy resulted in clinical evidences of improved nutrition and liver function and reduction of portal hypertension. A fall of serum bilirubin concentration and sulfobromophthalein retention and rise in serum albumin concentration were usually noted. This form of therapy for portal hypertension may be an alternative to surgical treatment in suitable patients if future study shows that as good or better results accrue.

IMPROVED APPROACH FOR POSTERIOR UPPER THORACIC SYMPATHECTOMY

Hunter J. MacKay, M.D., Seattle

The still popular and standard procedure for posterior upper dorsal sympathectomy was designed and described by Adson,[1] first in 1929 and again in 1931. Experimenting with midline, transverse, and hockey-stick skin incisions only to discard them, he finally adopted the well-known oblique paramedian skin incision. Irrespective of the site, incision is continued down only to the trapezius fascia, followed by undesirable division and separation of the large upper back muscles away from the midline to expose several centimeters of ribs and transverse processes. A large extent of rib and its entire transverse process must then be removed to permit the necessary additional excision of the resected rib neck and head. Distant from the midline, the parietal pleura is intimately applied to the ribs, intercostal muscles, and fascia; the intercostal neurovascular bundles are fixed in the concave costal surfaces, and the superior intercostal artery can occasionally become a problem.

These various architectural obstacles combine to make extensive exposure of the sympathetic chain, positioned immediately subjacent to the rib heads, an awkward, time-consuming, and perilous task. The needless gross muscle division and separation, which has always disturbed me, is also the source of the distressing and prolonged postoperative upper back discomfort almost routinely encountered by the patient, especially when sympathectomy is done on both sides. Other methods of sympathectomy are even more objectionable. The Schulze and Goetz axillary approach via the second intercostal space [2] is equally formidable and needlessly extensive, as are other transpleural procedures, especially when dealing with cardiac problems. Gaza's intercostal space ganglionectomy after transversectomy without rib resection [3] does not provide adequate visualization. Foerster's intradural operation and Guleke's extradural dorsal ramicotomy [3] are both unjustifiably hazardous and subefficacious. Although I was one of Adson's pupils, I have found his operation onerous and too time-consuming. Postoperative complications were too frequent and the morbidity too high for complacence and satisfaction. Accordingly, in October, 1951, I attempted the most direct approach to the upper dorsal paravertebral space and its contained sympathetics that I could conceive. Consisting of a limited upper dorsal costotransversectomy, via a midline laminectomy type of exposure, it proved so simple, speedy, and satisfactory in every regard that it was used in 14 other upper dorsal sympathectomies by myself and my late associate Paul G. Flothow, who previously commented on this technique.[4]

ANATOMIC CONSIDERATIONS

Anatomically, the most direct route to the dorsal sympathetics is via a midline laminectomy type of ex-

posure (fig. 1) for unilateral or bilateral sympathectomy at either one or two operations. Manifestly, but a portion of the transverse process and underlying rib neck need be removed. Two incisions are avoided, cutting and retraction of the large back muscles are obviated, lengthy extent of rib need not be sacrificed, the sympathetic chain is remarkably apparent medial to the ventrad pleural reflection, and depression of the pleura with a lighted retractor is totally unnecessary. Illumination is excellent under ordinary operating room conditions, and the procedure is quickly and comfortably completed under direct vision rather than by a struggle laterally under a virtual overhang or shelf of tissue. The sympathetic chain is so accessible that the operator is at first likely to remove it in part when biting away the rib necks, not realizing its proximity (fig. 1). Although no precedent for this approach appears in the literature the orthopedists understandably overlooked this relationship in devising costotransversectomy drainage of tuberculous spinal abscesses. Neurosurgeons have likewise ignored this path to the sympathetics when performing similar procedures for the removal of dumbbell spinal tumors.

Fig. 1.—*A*, dorsal aspect of upper thoracic spine as seen at operation, illustrating limited costotransversectomy and accessibility of the sympathetics. *B*, oblique view, showing extent and location of rib and transverse process resection.

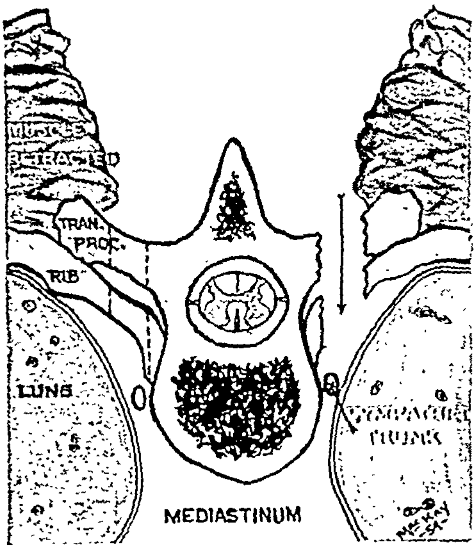

Fig. 2.—Cross sectional view of thorax at level of second rib, showing direct posterior approach to the upper thoracic sympathetics via a limited costotransversectomy and midline laminectomy type of exposure.

TECHNIQUE

It makes little or no technical difference whether sympathectomy by this approach is performed in the upright or face-down laminectomy position insofar as ease and comfort are concerned. I personally insist on the upright sitting position, however, in the firm and definite conviction that persons with cardiac disease, in particular, are thus given every physiological advantage. If such facility is not available, a lateral or oblique modified Sim's position is preferable to the usual full face-down position, which should never be used for a patient with heart disease.

A midline incision is centered over the second thoracic vertebral spine when sympathetic denervation is contemplated for upper extremity vasospastic conditions via resection of the second or third transverse process and rib for the Smithwick procedure, recalling that the second is the first palpable rib. If more extensive denervation for cardiac lesions is intended, incision is extended downward to the fourth or fifth thoracic spine. A typical subperiosteal exposure of the appropriate vertebral spines and laminas is done in the usual manner, on one or both sides. This maneuver is continued laterally, as for routine laminectomy, to the point where the bulbous tips of the transverse processes commence their dorsad upsweep (fig. 1*A* and 2), exposing the longitudinal gutter formed by the laminas and articular facets medially and the transverse processes laterally.

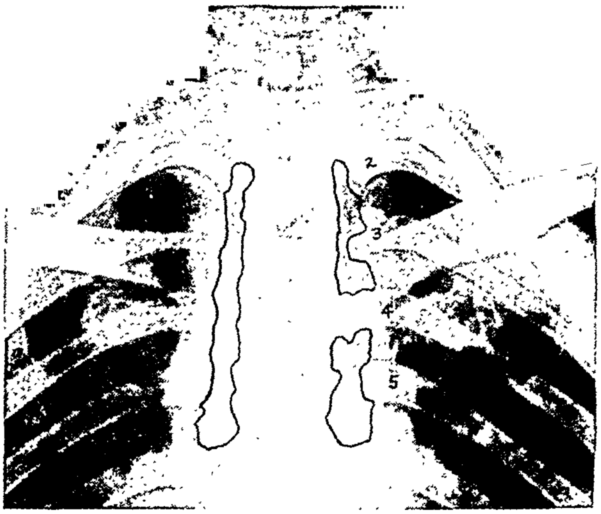

Fig. 3.—Postoperative thoracic spine, showing resection of four ribs and transverse processes on left and three on the right in patient with disabling coronary pain.

The root or stem of the transverse process, which is about 1 cm. in extent, is removed with an angular cranial rongeur, thereby uncovering the neck and head of the underlying rib medial to its articulation with the tip of the transverse process (fig. 2). In this plane, the ventrad reflection of the pleura has already begun and the intercostal neurovascular bundles are not yet intimately associated with the ribs. Nevertheless, as the transverse process is removed, the areolar tissue will be seen to rise and fall between the rib necks with each excursion of the underlying lung, but the pleura itself remains a safe distance removed. The intercostal, intertransverse, and costotransverse ligaments are quickly, easily, and safely stripped from the rib neck with a sharp curved periosteal elevator. Removal of 1 cm. of rib neck, leaving the articulating portion of the rib head in situ, immediately exposes the sympathetic chain, which is not adherent to the vertebral bodies at this level. Additional working space is unnecessary, but, if it is desired, more rib and transverse process can be readily removed medially witn a Kerrison rongeur or a Gilpi perineal retractor can be positioned between the rib end and lamina. It is even quite possible to remove the sympathetics without removing any rib whatever, but this procedure does not adhere to sound surgical principles.

This technical presentation is not concerned with the indications for, nor the actual extent of, upper thoracic sympathectomy. I follow the Smithwick preganglionic procedure via the second or third rib for vasospastic conditions of the upper extremity, except for ligating and dividing the second and third intercostal nerves central to the thoracic root ganglions in lieu of avulsing the roots intrathecally. A short vertical midline or transverse incision leaves minimal traces, which women appreciate. Removal of ganglions T-1 through T-5 (or T6) bilaterally for anginal pain and/or decompensated hearts is necessary and easily accomplished by resection of the second and fourth transverse processes and ribs. The individual operator may also choose to remove the transverse process and rib of T-3 rather than work the sympathetic chain upward beneath it, although this can readily be done. If the removal of ganglion T-6 is also intended, it is better to resect part of the second, all of the third, and all of the fifth processes and ribs. Resection of any or all processes and ribs is permissible, and the amount resected varies with the surgeon (fig. 3). It is occasionally possible to remove the entire stellate (vertebral) ganglion via the second transverse process and rib, provided that gentle traction on the sympathetic trunk delivers it into the upper part of the exposure. The vertebral artery will then be visible anterior to the ganglion, clasped by its tentacle-like rami.

Closure is completed by anatomic approximation with interrupted silk sutures as for any upper thoracic laminectomy. There has been but a single instance of wound disruption in an early case in which catgut was used; the disruption was due to the patient's self-violence during a brief postoperative psychotic episode.

COMMENT

This is a virtually bloodless procedure possessing the main advantages of speed, directness, accessibility of the sympathetics, and avoidance of hazards and morbidity. In serious cardiac conditions, extensive bilateral sympathectomy performed with the greatest facility in the shortest time is of the essence. This is routinely accomplished by the described method in half the time (or less) required for unilateral denervation of but the upper three thoracic ganglions by the Adson approach.

In addition to the more obvious benefits and advantages of this new route, the patient is spared prolonged anesthesia, sustains less trauma, has a single midline incision, and enjoys early mobilization (one to two days) and discharge, which is currently of great economic importance. For me, this procedure is a pleasure rather than a chore, spares time and trauma to patient and surgeon alike, and thus far has not revealed any disadvantages.

Although this approach allows cervicothoracic sympathectomy, the anterior approach remains speedier, easier, and less traumatizing for removal of the stellate ganglion alone or for combined removal of the stellate ganglion and postganglionic resection of the second and possibly the third thoracic ganglions. This is especially true when a modification of the usual anterior approach is used.

SUMMARY AND CONCLUSIONS

A new and improved posterior approach to the upper thoracic sympathetics, used for unilateral or bilateral upper thoracic sympathectomy, has the following advantages: (1) single midline incision and laminectomy type of exposure without muscle division; (2) minimal transverse process and rib resection; (3) direct access to the sympathetic chain medial to the pleural reflection with excellent visibility by ordinary surgical lamps; (4) wound quickly and securely closed; (5) bloodless procedure without intrathoracic complications; (6) operating time decreased by at least 50%; (7) less trauma to the patient by conservation of time, tissue, blood, and anesthesia; (8) greatly diminished postoperative morbidity, allowing earlier ambulation and shorter hospitalization.

While no distinct disadvantage is known, postganglionic cervicothoracic sympathectomy by the modified anterior approach is preferable. This described technique has proved eminently satisfactory and gratifying in 14 cases of posterior upper thoracic sympathectomy (5 unilateral and 9 bilateral, eight patients with heart disease, four with Raynaud's disease, one with causalgia, and one with Ménière's disease).

Multiple Polyposis of the Colon.—[This condition is] characterized by the occurrence of numerous polyps throughout the colon and/or rectum. The polyps usually make their appearance during the first and second decades of life, but occasionally may not arise until the fourth decade or possibly even later. Although the polyps themselves may be associated with symptoms referable to the large bowel, the disease is of clinical significance primarily because of the tendency of one or more of the polyps to become malignant, with death from carcinoma of the colon or rectum at a relatively early age. The disease has long been known to have a familial distribution. . . . Approximately 10 per cent of all adults can be demonstrated by combined sigmoidoscopic and X-ray studies to possess one or more polyps of the colon. However, only a small fraction of these persons has true multiple polyposis. When appropriate diagnostic studies are carried out, there is seldom any problem involved in differentiating between the person who has hundreds or even thousands of polyps—and has multiple polyposis—and the person who has two or three, or even five polyps, but does not have the multiple polyposis with which this study is concerned. The two diseases with which multiple polyposis can most readily be confused are the so-called Peutz-Jeghers syndrome of diffuse intestinal polyposis and abnormal pigmentation, and the syndrome of polyposis of the colon associated with osteomatosis and fibromatosis. Both of these diseases are apparently much rarer than classical multiple polyposis.—T. E. Reed and J. V. Neel, M.D., A Genetic Study of Multiple Polyposis of the Colon, *The American Journal of Human Genetics*, September, 1955.

SCIENTIFIC BASIS FOR THE SURGICAL TREATMENT OF CORONARY ARTERY DISEASE

Claude S. Beck, M.D.
and
David S. Leighninger, M.D., Cleveland

To understand the scientific basis for the surgical treatment of coronary artery disease it is necessary to analyze information obtained by experiments on dogs. One of us (C. S. B.) and his associates have done about 5,000 operations on the coronary blood vessels in the last 23 years, and these are the basis for this presentation. There are several variables inherent in this work, and it is appropriate here to state that these must be properly taken care of, otherwise erroneous conclusions will be made. A report on much of this experimental work has been published in The Journal.[1] In these experiments the reduction in coronary artery inflow was produced by placing ligatures around the coronary arteries. In the human, arteriosclerosis produces reduction in coronary artery inflow. The net result is reduction in arterial inflow. This is not a study of arteriosclerosis. Even if this disease could be produced experimentally in adequate numbers of dogs the occlusion probably could not be localized nor could the degree of occlusion be controlled with the precision demanded by the experiment, and as a method of investigation it would be inferior to the ligature.

The surgical treatment of coronary artery disease is based upon four considerations. 1. Operation adds 4.7 cc. of blood per minute (282 cc. per hour) to an area of myocardium made ischemic by complete ligation of the artery that normally feeds this muscle. This quantity of blood is of little or no significance if it is delivered to myocardium that is fed by a normally patent artery or if the artery is occluded by three-fourths of its diameter. But if the artery is totally occluded then this quantity of blood is protective. When the circumflex artery is ligated in a normal dog the average amount of blood available to the muscle beyond the ligature is 3.8 cc. per minute. Operation adds 4.7 cc. to this quantity, making an average total of about 8.5 cc. per minute. 2. This quantity of blood accomplishes three favorable results: It reduces mortality following test coronary artery occlusion, it likewise reduces the size of the infarct in these dogs that live following the arterial occlusion, and it provides time for additional blood to run into this low pressure area of occlusion from adjacent high pressure areas of myocardium. In a few days this ischemic but viable myocardium begins to contract. In 24 dogs the average amount of blood available to the myocardium beyond the ligature was 62 cc. per minute. 3. Of all the people who die of coronary artery disease about 90% die because the heart becomes electrically unstable. The hearts in these people are capable of continued function under slightly altered circulatory conditions, and these are the patients who can be helped by surgical operation. The remaining 10% of the patients who die from coronary artery disease have extensive myocardial degeneration, and these patients die in circulatory failure. Little or nothing can be accomplished by surgical operation in these patients (fig. 1). 4. The transfer of this information from the laboratory to the human patient is being made without conflict in the science.

ELECTRICALLY STABLE AND UNSTABLE HEARTS

An electrically stable heart is a uniformly well oxygenated heart. Emphasis is placed upon the uniformity of oxygen tension throughout the myocardium (fig. 2*A*). Stability persists when the oxygen tension is reduced provided the reduction is uniform throughout the myocardium. A uniformly cyanosed heart is also a stable heart, as indicated by observations made in our laboratory on about 60 dogs in which the intratracheal tube was clamped off for periods of six to nine minutes. The heart in these experiments became increasingly cyanosed; it dilated; the beat became weak, and then it stopped in standstill. *In none of these experiments did* the heart fibrillate. When oxygen was again delivered into the lungs and the heart massaged a few times a strong vigorous beat was restored. Thus the mechanism

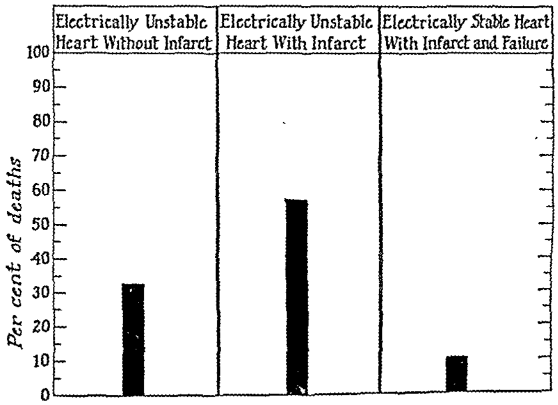

Fig. 1.—One-third of all victims of coronary artery disease have no infarct, either old or recent, according to Yater.[4] In this group, column 1, the hearts became electrically unstable. Approximately 10% of all victims die of circulatory failure. In this group, column 3, the currents incidental to progressive occlusions were never strong enough to fibrillate the heart and stability was maintained from one occlusion to another until failure supervened. Of the remaining 57%, column 2, both muscle damage and instability were present, and, in many of these specimens, the destruction of muscle was not so great but that continued function would have been possible were it not for the electrical potentials that destroyed the coordinated mechanism. In the first group of patients there was no muscle damage, and continued function was possible in this group, provided the heart remained electrically stable.

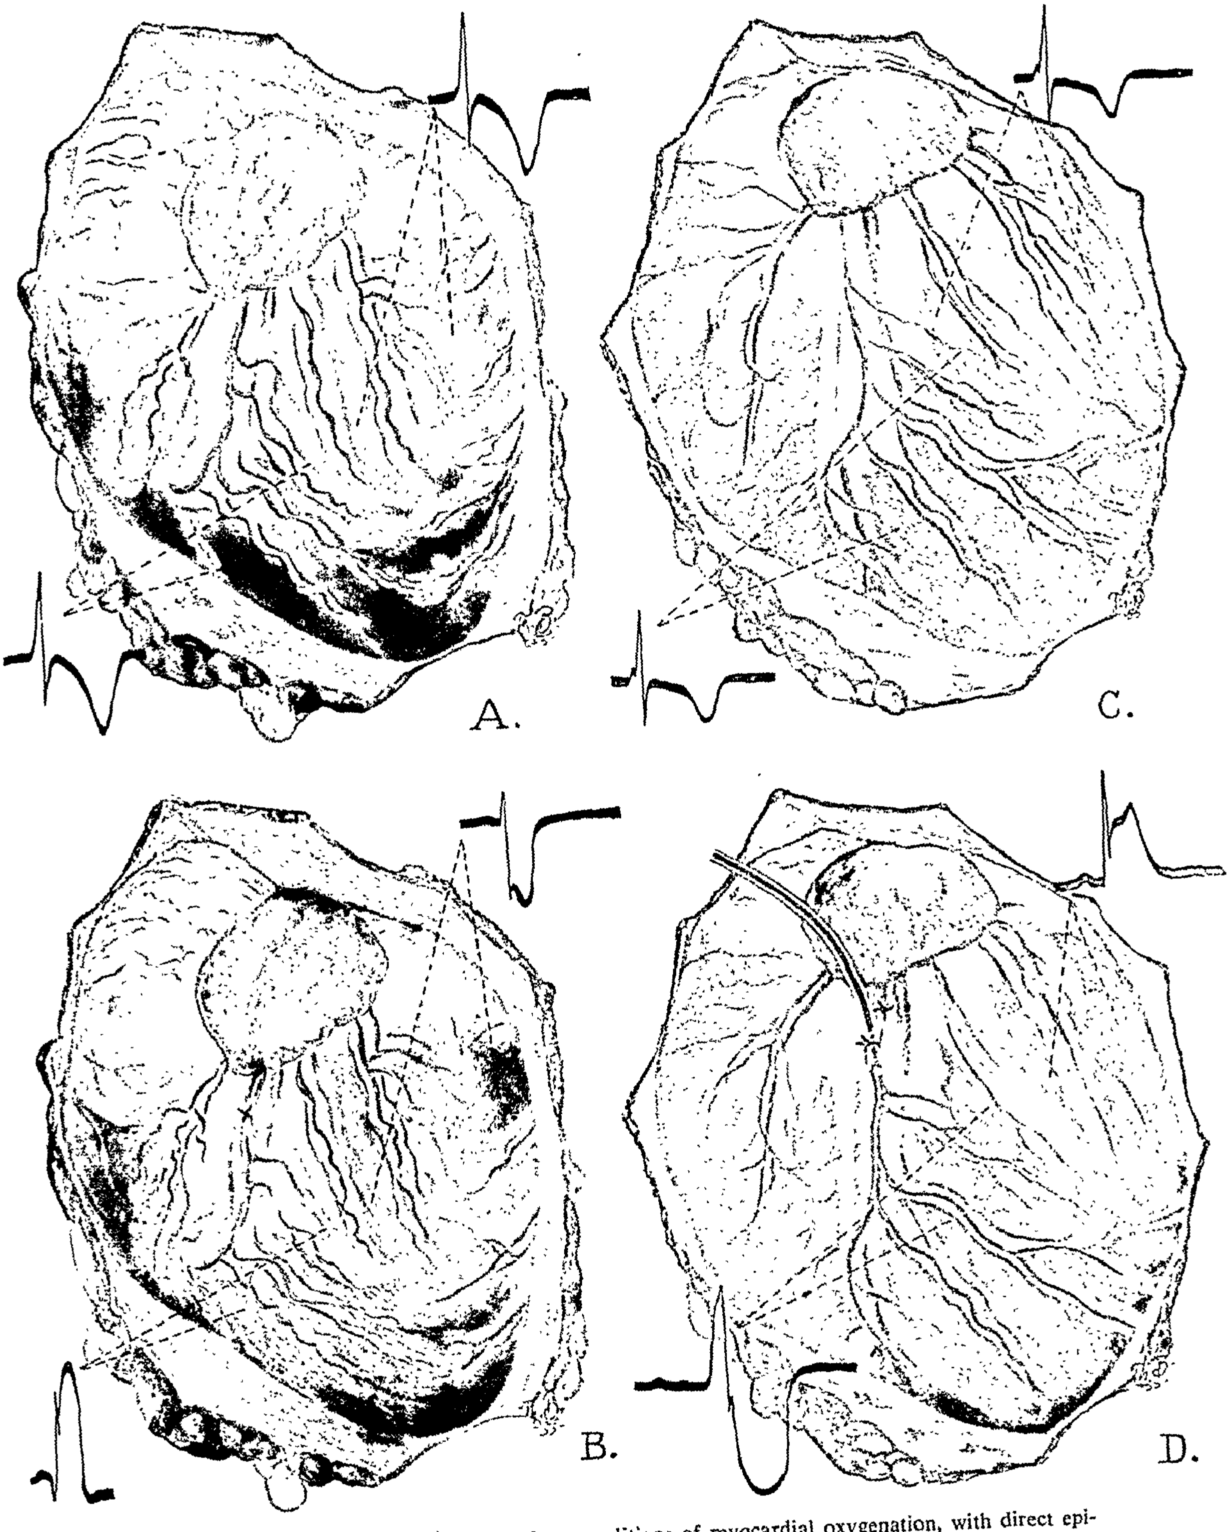

Fig. 2.—Dog hearts illustrating four conditions of myocardial oxygenation, with direct epicardial electrocardiograms demonstrating measurement of electrical potentials. *A* and *C* are the same heart; the one is uniformly well oxygenated, and the other is uniformly and severely cyanosed. These hearts are electrically stable as shown by the isoelectric S-T segment in each condition. *B* and *D* are electrically unstable because the oxygen *tension* in each heart is not uniform throughout. The S-T segment is depressed over the pink or well-oxygenated myocardium and elevated over the blue or cyanosed myocardium. These differences in potentials are often strong enough to fibrillate the heart. The term "current of oxygen-differentials" is introduced to replace "current of injury," which is obviously incorrect. A uniformly cyanosed heart is not an injured heart.

remained coordinated as the heart changed in color from pink to blue and back again to pink. Direct epicardial electrocardiograms taken from the surface of the uniformly pink and the uniformly cyanosed heart are shown in figure 2*A* and *C*. The heart becomes electrically unstable and may fibrillate when the oxygen tension is not uniform throughout the myocardium. Thus a cyanosed area surrounded by well-oxygenated myocardium or a well-oxygenated area surrounded by cyanosed myocardium are conditions that produce electrical instability. These conditions are produced experimentally by ligation of one or more coronary arteries in a well-oxygenated heart and by delivery of pink (arterial) blood through a catheter in a coronary artery in a deeply cyanosed heart. The appearance of these two types of trigger and the electrical potentials from the surface of these hearts are shown in figure 2*B* and *D*. These differences in electrical potential from pink and blue areas measure 5 to 20 mv.[2] They are produced at the precise plane of contact between blue and pink and pink and blue muscle. They are produced by differences in oxygen tension, and we use the term oxygen differential to refer to this phenomenon. The term "current of injury" has been commonly used to refer to currents produced by ligation of a coronary artery, but this term is probably not correct. The terms stable and unstable heart are also of recent origin and seem to have a place in cardiac nomenclature.

No doubt the amount of current and the voltage produced under experimental conditions vary in different dogs. The same current may fibrillate the heart in one dog and fail to do so in another. In different dogs and under different conditions there appears to be a difference in what might be referred to as the threshold for fibrillation. The threshold for fibrillation is lowered by hypothermia in the absence of coronary artery occlusion, and in a series of experiments in which the descending ramus of the left coronary artery was ligated the heart fibrillated in every experiment, whereas under normal temperatures the incidence of fibrillation was 50%.[3]

Electrical instability leads to fibrillation and death in a large number of people. The classic example of this occurs in the man who goes out and shovels snow and in a few moments is dead. The exercise improves oxygenation of myocardium everywhere except in an area supplied by a coronary artery that is not normally patent although it may not be completely occluded. In some instances the arterial disease is slight. Under these conditions an oxygen differential is produced that in turn produces sufficient current to fibrillate the heart. Had this man remained indoors without this vigorous exercise the circulation of red blood into the myocardium would have been less brisk; the heart under conditions of rest would have been less pink; and the oxygen differential probably would not have produced sufficient current to have fibrillated the heart. To society the loss produced by these currents is incalculable. These currents occur in people who could live productively provided small alterations were present in the coronary artery circulation. One-third of all victims of coronary artery disease have no damage in the myocardium, either old or recent,[4] and many of the remaining two-thirds have heart muscle that probably could continue to function for years were it not for these currents. In about 10% of the victims of coronary artery disease these currents were never severe enough to fibrillate the heart; the patient continued to live, and the occlusive disease advanced to the point where extensive damage and failure occurred. It appears then that oxygen differentials of a fatal nature can be produced in the absence or in the presence of myocardial destruction. It also appears that myocardial destruction can proceed to the stage of failure without producing currents strong enough to fibrillate the heart. The production of currents and the destruction of muscle are both related to oxygen, but they are different biological processes. The purposes of surgical operation are to reduce these currents and to preserve viability of muscle although the occlusive process may proceed later on even to the point of cardiac failure.

SURGICAL OPERATIONS

The principles for aiding a crippled coronary circulation were previously presented in THE JOURNAL.[1] According to our experience the most important aid is provided by the presence of intercoronary arterial communications, so that a red blood cell entering the descending ramus or one of its branches can get over to the circumflex ramus or one of its branches, where it fulfills a more important function. The addition of blood from outside sources is less effective than the distribution of blood that is already in the coronary system. We tried to add blood to the heart in many different ways, one of which was to enter it through the coronary sinus system of veins in a retrograde direction. This method provides the greatest amount of protection of all methods that we tested, but retrograde flow tapers off in the dog after six to eight weeks and is replaced by a protective set of intercoronary channels. Whether retrograde flow tapers off in the presence of coronary artery-inflow disease in the human patient cannot be stated at this time. Other sources of flow from the outside, such as from parietal pericardium, mediastinal fat, lung, internal mammary arteries, chest wall, omentum, spleen, and intestine grafted upon the heart, are yet to be measured.

Considerable work on this subject has been done, and anatomic channels large enough to carry blood have been demonstrated between graft and coronary arteries, but so far measurements of flow have not been done. No doubt these measurements will be made, because methods for measurement are available and some of these surgical procedures may be found to be effective. For the present we have laid aside the operation that diverts arterial blood into the coronary sinus system of veins because the long-term condition of the circulation in the human heart will not be known until a number of specimens are examined. This operation is technically difficult. It requires two stages. It has a definite mortality and also some side-effects from the arteriovenous fistula produced by the operation. However, as stated above, it produces the greatest amount of benefit, and we might apply it in those patients who still have pain after the number 1 operation has been used.

The Number 1 Operation.—The number 1 operation consists of the following steps. 1. The lining of the parietal pericardium and the surface of the heart are abraded or roughened by special burs. This produces mechanical trauma, which in turn produces inflammation and intercoronary arterial channels. We experimented with necrotizing chemicals for the removal of epicardium, but no satisfactory chemical agent has been found, and strong chemicals such as carbolic acid should not be used. 2. Application of 0.2 gm. of coarsely ground asbestos is made to the entire surface of the heart. This produces mild inflammation, which persists for a period of months and which in turn produces intercoronary arterial channels. We experimented with many different inflammatory agents, and asbestos is the most effective agent. 3. The coronary sinus is occluded to a diameter of 3 mm. Ligation of this vein is not beneficial when the arterial circulation in the heart is normal because it reduces arterial inflow, but when a major coronary artery such as the circumflex is occluded then ligation of the sinus affords protection against loss of coordinated mechanism, and it also provides for greater absorption of oxygen from the blood in the occluded vascular bed.[5] Ligation also aids in the development of intercoronary arterial channels. 4. Parietal pericardium and mediastinal fat is applied to the surface of the heart. This grafted tissue stimulates the development of intercoronary arterial channels and in some instances probably becomes the source of additional blood to the heart.

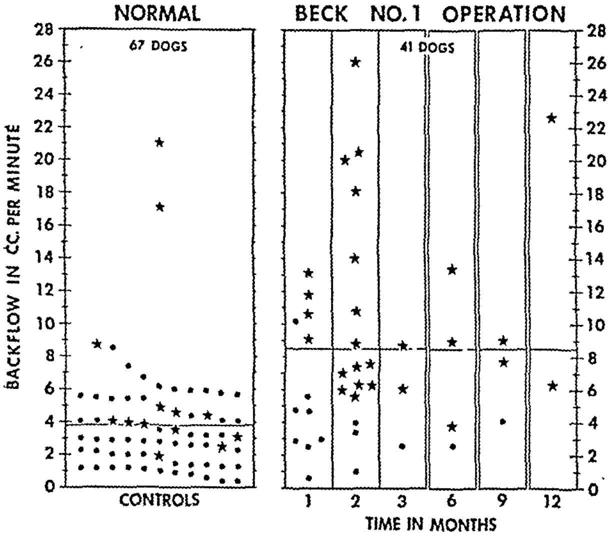

Fig. 3.—Mautz-Gregg backflow measurements in normal control dogs and in dogs upon which number 1 operation was done. Average in 67 normal dogs was 3.8 cc. per minute and in 41 dogs in which the number 1 operation was done was 8.5 cc. per minute. This increased backflow was present one year after operation. Star indicates that electrocardiographic evidence of protection was present, and solid circle indicates it was absent.

This operation has been well tested in the experimental laboratory. The protection of the number 1 operation in terms of mortality and size of infarct has been reported.[1] In normal dogs the mortality following complete ligation of the descending ramus of the left coronary artery at its origin in one step was 70%. In 30 dogs in which the number 1 operation was done and sometime thereafter the same artery was ligated, the mortality was 26.6%. This is a reduction of 43.4% produced by the operation. The hearts in each group that survived test artery ligation were examined and the size of the infarct measured. In the hearts that were protected by operation the infarct was 60 to 70% smaller than in the control group. In some specimens there was no gross infarct, and this was never observed in a specimen of the control group.

Backflow.—The Mautz-Gregg method of backflow yields important information and was used in many experiments.[6] This method consists of ligation of either the circumflex ramus or the descending ramus of the left common coronary artery. One of these vessels is ligated proximally and cut distal to the ligature. The amount of blood from the cut artery is the backflow. A third measurement of protection, which has also been reported,[1] consists of the response made by the circulation *after test artery ligation, provided the animal lived and* the heart muscle was not destroyed by the ischemia. Backflow measurements made in an artery that was occluded one day were 10.8 cc. per minute; two days, 42.0 cc.; three days, 68.0 cc.; and six days, 20.0 cc.; the average up to four months in 24 dogs was 62.1 cc. per minute. The important consideration here is the fact that 4.7 cc. per minute of additional blood provided by operation carried the dog over the crisis of the arterial occlusion and also preserved the viability of myocardium. Under these conditions additional blood ran into the ischemic, low-pressure myocardium from adjacent myocardium where the pressure was higher, and later on this ischemic but viable myocardium had sufficient blood *supply to restore contractility to this area of myocardium.*

[6] Mautz, F. R., and Gregg, D. E.: The Dynamics of Collateral Circulation Following Chronic Occlusion of Coronary Arteries, Proc. Soc. Exper. Biol. & Med. 36: 797 (June) 1937.

Recent measurements obtained by one of us (D. S. L.) are presented in figure 3. In 67 normal dogs the average backflow was 3.8 cc. per minute. After the number 1 operation was done the backflow in 41 dogs was 8.5 cc. per minute, or an increase of 4.7 cc. This increase in backflow was found one year after operation, so that the improvement is probably of a permanent nature. The relationship between backflow and electrocardiogram is shown in figure 4. Any quantity of blood added to that which is already present is protective. When the total quantity of backflow is 6 to 10 cc. per minute the electrocardiogram shows S-T segment depression less than 2 mm. and is indicated by a star. When the total backflow is 2 to 4 cc. per minute it shows greater S-T segment depression or the heart may fibrillate, and this is indicated by a solid circle. The various components of the number 1 operation were measured, and these are shown in figure 5. Each component contributes something to the backflow.

Thompson[7] advocated the introduction of 4 to 6 gm. of talc into the pericardial cavity for the treatment of coronary artery disease, and backflow in such experiments is given in figure 6. The average backflow in 20 dogs was 4.8 cc. per minute. This figure is 1.0 cc. greater than the average normal but is 3.7 cc. less than obtained in the number 1 operation. Vineberg[8] implanted the internal mammary artery into the myocardium of the left ventricle for the treatment of coronary artery disease. This artery is ligated and severed, but an intercostal branch is left open. The artery is placed in a tunnel in the myocardium with the expectation that branches will develop from it and these branches will connect with the smaller branches of the coronary arteries. Backflow measurements were made, and the results are shown in figure 6. The average backflow in 20 dogs was 3.9 cc. per minute. This operation did not increase backflow measurements over the normal, and the measurements were about the same with the mammary artery occluded by clamping or not occluded. In these experiments there was no increased backflow even from intercoronary arterial channels. When the artery was severed the proximal end bled freely but the distal end yielded either no blood or less than one drop per minute. Vineberg stated that the implant should be made into ischemic myocardium for anastomoses to develop, and that was not done in these experiments.

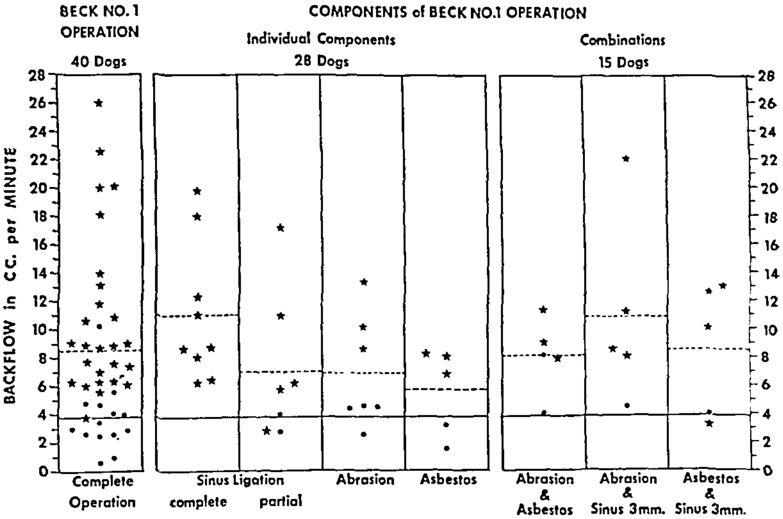

Fig. 5.—Mautz-Gregg backflow and various components of number 1 operation. Solid horizontal line indicates the average normal backflow. Broken lines indicate average backflow in each procedure. Each procedure adds something to backflow.

OPERATION ON PATIENTS

The patient is given 0.6 mg. of atropine sulfate and 10 mg. morphine sulfate one-half hour before being moved to the operating room and in the operating room is given 50 mg. of diphenhydramine (Benadryl) hydrochloride intravenously together with 0.4 gm. of thiopental (Pentothal) sodium and 60 mg. of succinylcholine chloride. He is given 100% oxygen for three to six minutes, and he is then intubated with a properly fitting cuffed endotracheal tube. Ether and oxygen are then given, and respiration is assisted until he breathes on his own. The next step is the intravenous administration of 10.5 mg. of tubocurarine chloride. The Rand-Wolfe mechanical respirator is used and is recommended. Nitrous oxide and oxygen, 5 liters of each, making a flow of 10 liters per minute, are given. A little ether is given, but usually curare and nitrous oxide maintain the anesthesia. The amount of ether used is about 2 to 3 oz. (60 to 90 cc.) per patient. We do not use rebreathing.

The drugs used are as follows: pentobarbital (Nembutal) sodium, 0.2 mg., given the night before operation; digitoxin (Crystodigin), 0.1 mg., given just before the patient is moved to the operating room; and desacetyllanatoside C (Cedilanid-D), 0.2 mg. given intravenously if the heart rate is over 110 beats per minute. This is repeated if necessary, or 0.4 mg. may be given in one dose. This digitalis preparation for intravenous use is an important aid in slowing the heart rate, and its use should not be overlooked. It requires 20 minutes to become effective. Atropine in doses of 0.2 to 0.4 mg. is given intravenously for nodal rhythm. Procainamide (Pronestyl) hydrochloride, 100 mg. diluted 10 times in saline solution, is given intravenously for ventricular extrasystoles. Tachycardia and S-T segment changes in the electrocardiogram are treated by stopping the operation for several minutes and oxygenating the lungs well. The lungs should come up well and then relax with each respiration. If the blood pressure falls, mephentermine (Wyamine) sulfate, 7.5 mg., is given intravenously and twice this amount is given intramuscularly.

The patient is placed on his right side with the left side up. If the blood pressure falls below 90 mm. Hg the operation is not started. Time is taken to observe the blood pressure. If the pressure remains below 90 mm. Hg for the next half-hour, the operation is not done

8. Vineberg, A.; Munro, D. D.; Cohen, H., and Buller, W.: Four Years' Clinical Experience with Internal Mammary Artery Implantation in the Treatment of Human Coronary Artery Insufficiency Including Additional Experimental Studies, J. Thoracic Surg. **29**: 1 (Jan.) 1955.

and the patient is not acceptable for operation. By experience we learned to regard this as a rule not to be broken.

The incision is placed between the sixth and seventh ribs, extending from a point about 8 cm. from the midline in front to a point about 6 cm. from the midline in back (fig. 7). The ribs are spread apart by a self-retaining retractor for a distance of 12 to 14 cm. The pericardium is opened by an incision from apex to base about 4 cm. to the right of the left phrenic nerve. Traction sutures are placed in the pericardium and held up by the weight of a hemostat. The lining of the parietal pericardium is abraded everywhere by special burs. Another incision is made parallel to the first incision but to the left of the nerve, and a third incision splits the pericardium at right angles down to the coronary sinus. Traction sutures are applied to the cut edges of the pericardium (fig. 8). Exploration of the myocardium and coronary vessels is carried out. The common left coronary artery is lightly palpated by the right index finger. This vessel is normally patent, thickened but pulsatile, or it may be calcified. The descending ramus is palpated, as is also the first part of the circumflex ramus. The branches of these vessels are observed as to pulsation, beading, or streaking. The myocardium is observed for the presence of an infarct. The infarct is observed for size, location, and paradoxical pulsation. The coronary sinus is observed.

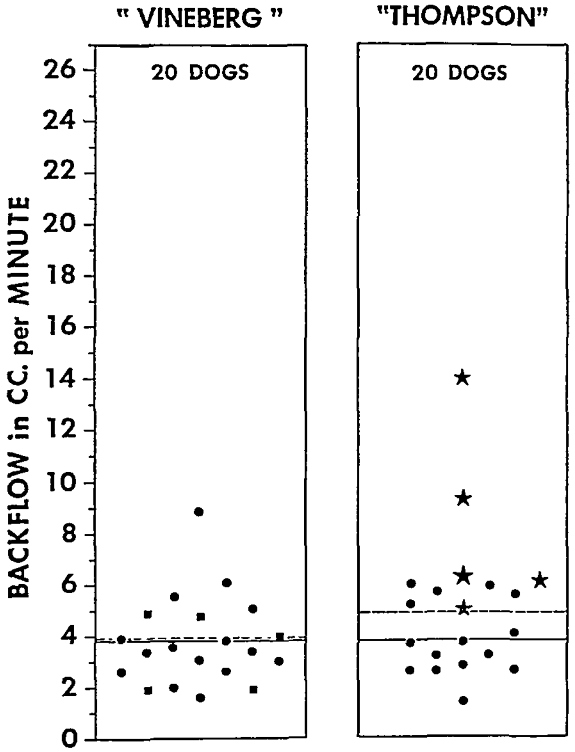

Fig. 6.—Mautz-Gregg backflow measurements in two groups of dogs. In one group the Vineberg procedure was done. Average backflow was 3.9 cc. per minute; in normal dogs it is 3.8 cc. per minute. In the other group the Thompson procedure was done. Average backflow was 4.8 cc. per minute, which is 1 cc. greater than normal.

A point is selected between the middle and posterior veins of the ventricle. The epicardium just below the sinus is nicked with scissors, and a small opening is made and the tissues are gently spread with the point of a hemostat, separating the sinus slightly from its bed. A curved needle that contains silk is passed directly into the right auricle parallel to the sinus. This curved needle is then turned 90 degrees so that the point comes out of the auricle just superior to the sinus (fig. 9). The circumflex artery lies close to the passage of the needle, but with care it can always be missed. The ligature is tied around the sinus plus a stilet 3 mm. in diameter. The stilet is removed and partial occlusion of the sinus is accomplished (fig. 10). This ligation is done after the surface of the heart is abraded (fig. 11) and also after 0.2 gm. of coarsely ground asbestos is applied to the surface of the heart (fig. 12). The mediastinal fat is then brought into contact with the heart over as wide an area as possible, and the pericardium is loosely closed (fig. 13). A drainage tube is placed in the left pleural cavity and attached to a water-seal. If a cartilage is broken, it is carefully wired together. The sixth and seventh ribs are sutured with a wire. The soft parts are closed with silk. The patient is given oxygen intranasally or is placed in an oxygen tent for 24 hours and ambulation is started. The patient is discharged in about two weeks.

INDICATIONS FOR AND LIMITATIONS OF OPERATION

Operation is indicated in the treatment of coronary artery disease. Any patient in whom the diagnosis of this disease is established is a candidate for operation provided the disease has not advanced to the point where the risk of operation is too great. Diagnosis will not be discussed. The problem is to determine the stage of the disease when the operation should or should not be

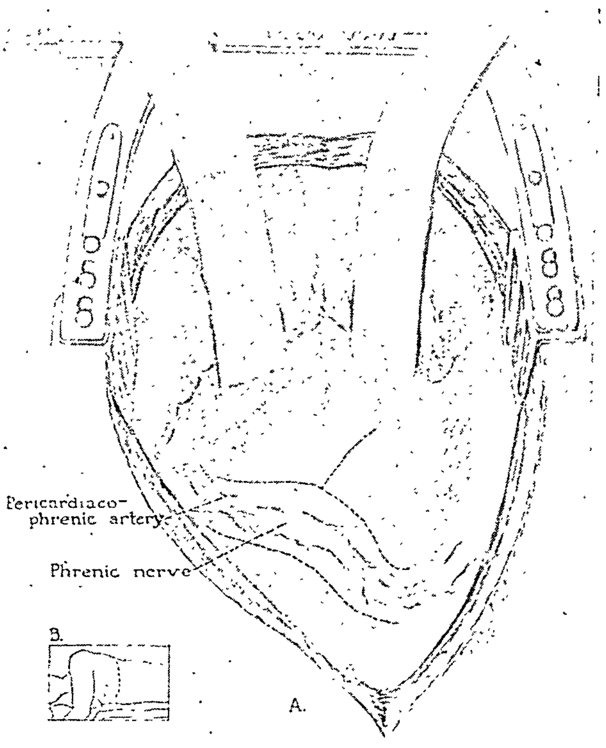

Fig. 7.—Left side of chest is opened by incision between the fifth and sixth or sixth and seventh ribs as indicated in the inset. The pericardial incisions are indicated by the broken lines.

done. Patients with signs of failure, nocturnal dyspnea, and marked enlargement of the heart are almost automatically excluded. Patients with slight or moderate enlargement of the heart without failure are accepted. Operation is delayed in patients with rapidly increasing pain and disability because these symptoms may indicate progress of the disease and an impending infarct. If decision for or against operation is difficult, it is advisable to delay decision for several months after which reappraisal is made. Patients with status anginosus have been accepted. We prefer not to accept patients addicted to drugs, but in several patients this habit, if present, was broken. Operation is indicated early in the course of the disease rather than late. The experience usually has been that the disease is worse at the operating table than anticipated.

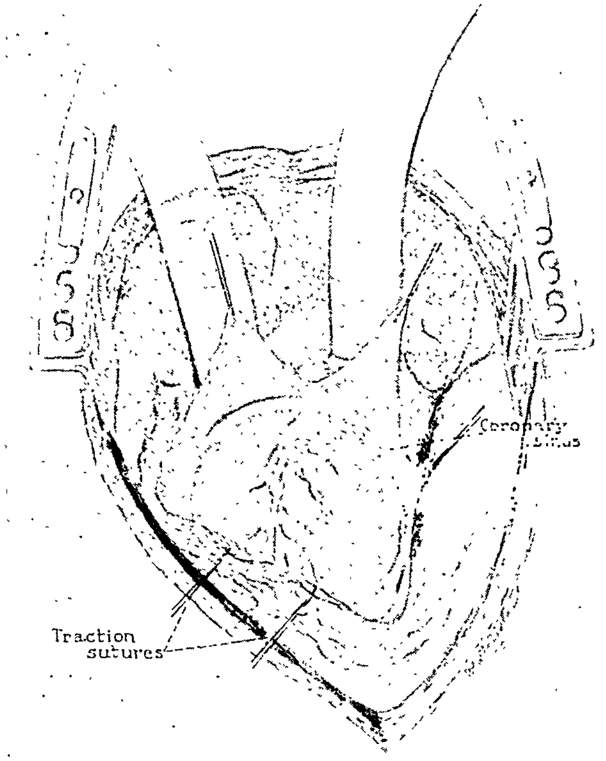

Fig. 8.—Pericardium opened for observation of coronary arteries, myocardium, and coronary sinus. Common left coronary artery and circumflex ramus of left artery cannot be seen but can be palpated. Right coronary artery cannot be seen or palpated.

After an infarct has occurred, a period of four to six months is given before operation is done. This delay serves several purposes. It affords time for intercoronary channels to develop after the low pressure bed has been established by the occlusion, and clinically it gives the patient time to "level off" so that his condition can be compared before and after operation. Also, electrical instability accompanies occlusion, and an anesthetic plus manipulation of the heart at operation may lead to ventricular fibrillation. This instability becomes less after the scar has formed and has become electrically inert. Another reason for delay applies to patients in whom one occlusion is followed by another. These patients have progressive arterial disease, and they are not candidates for operation. The disease is more likely to be progressive in patients in the 20's and 30's than those in the 40's, 50's, and 60's. The youngest patient operated upon was 27 years of age and the oldest 71.

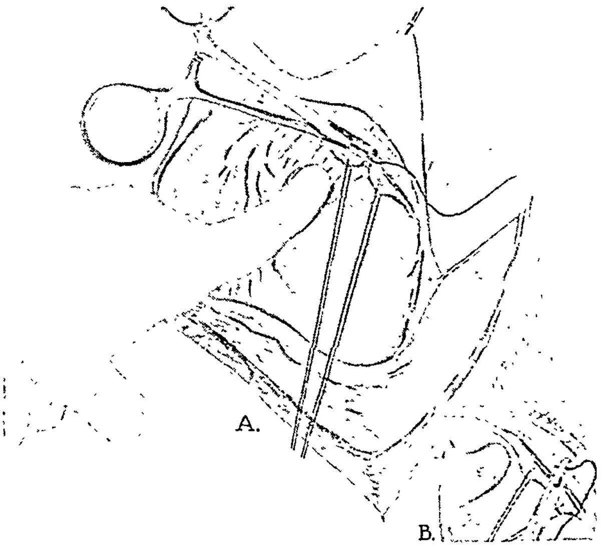

Fig. 9.—Placing a suture around the coronary sinus; *B*, needle penetrating the left atrium in a direction parallel and close to the sinus. Needle is then turned in a clockwise direction 90 degrees to emerge just superior to the sinus. Temporary traction sutures are in the fat to expose sinus.

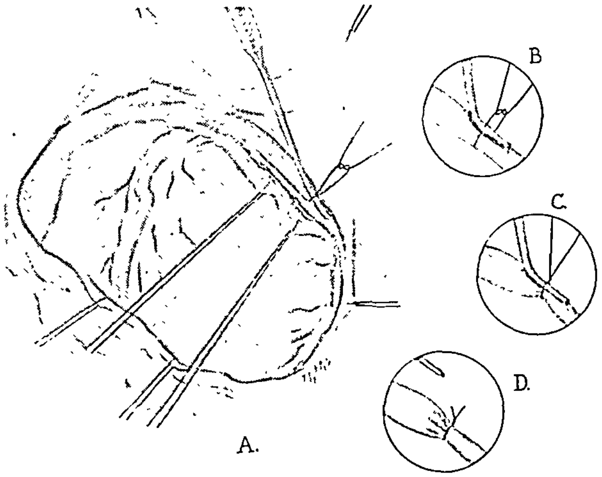

Fig. 10.—Partial ligation of the coronary sinus. The ligature is tied on a stilet 3 mm. in diameter, as in *A*, *B*, and *C*, and the stilet is removed after the ligature is tied, as in *D*.

The operation has limitations that, if properly understood, will make its beneficial effects more readily acceptable. It does not treat coronary arteriosclerosis; it treats alterations in inflow produced by the disease. It therefore does not reduce the disease in the arteries, nor does it stop its progress. It may become more marked after operation. A similar statement may be made about the myocardium. Operation does not restore an infarct to functional myocardium; however, it does reduce the size of the infarct or even prevent the formation of an infarct if another artery becomes occluded. It is possible for the symptoms to become worse in a patient who has shown clinical improvement after operation. This is brought about by the progress of the arterial occlusion, so that it is possible for the patient to be in worse condition clinically sometime after operation; yet the operation has saved the patient's life. The patient may die of coronary disease sometime after operation, but the experience so far seems to indicate that the operation prolongs life.

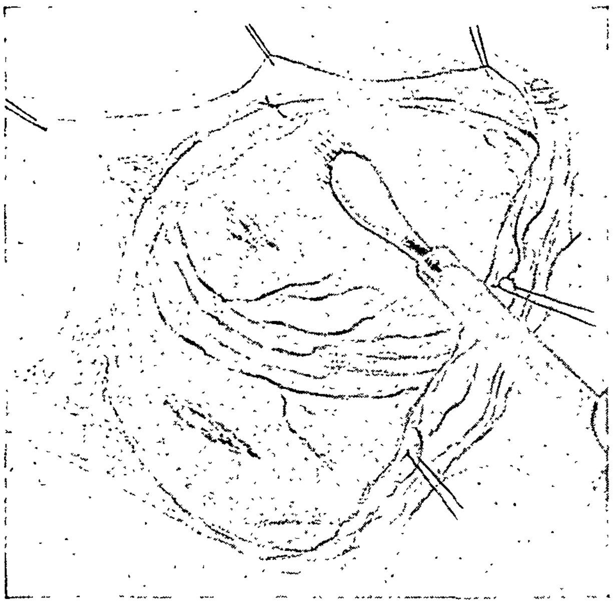

Fig. 11.—Epicardium removed by special burs. Necrotizing chemicals should not be used for this purpose.

RESULTS OF OPERATION

The results of operation can be determined by three measurements, as follows: (1) symptoms before and after operation, using the patient as his own control; (2) ability to work and to exercise, again using the patient as his own control; and (3) prolongation of life after operation. The first two items are shown in figure 14. Approximately 90% of the patients have less anginal pain or no anginal pain after operation. Several patients were operated upon who did not have any pain before operation, and these are not counted in these results. Some patients state that the angina is better three days after the operation. This improvement may be mental, but early changes in the circulation, as shown by experiment, do occur. When such mild therapy as a small quantity of whiskey or a glyceryl trinitrate (nitroglycerine) pill can reduce angina, it is not inconceivable that a few drops of blood to ischemic muscle could also give relief. As a rule the patient operated upon for coronary artery disease complains less of incisional pain than does the patient operated upon for mitral stenosis, and the incision in each is almost the same.

Some patients do not show improvement for several months after operation. The explanation for this cannot be given. A small percentage of the dogs failed to show increased backflow after operation. About 10% of the patients do not show any improvement after operation, and this aspect of the problem requires further investigation. Some of our patients are classified as salvage. These patients have severe arterial disease in the common left coronary artery or in each of the major branches of this artery. They also have extensive infarcts, sometimes with aneurysm of the myocardium. In these patients not only is the operative risk high but it is often difficult for us to understand how they can be helped by the operation, and yet some of the best clinical results are obtained in this salvage group.

The best results are almost unbelievably good. In some patients pain and disability are completely relieved. Such almost miraculous results are occasionally seen in patients without operation, and the explanation is the same as in the operated patients. Each patient develops a good set of intercoronary channels, one without operation, the other after operation, and the occlusive disease does not get worse. The end-result is the same. Indeed, operation accomplishes what nature can do but fails to do in a sufficiently large number of patients. In about 90% of the patients the ability to work is improved. Many of the patients return to jobs that they could not do before operation. It is gratifying to see this type of result; however, the patient is advised before operation that there is a good probability he will be better after operation but that he will not be cured of his disease.

It is difficult to make definite statements concerning the prolongation of life after operation. The arteriosclerotic process in the coronary arteries follows a variable and unpredictable course. These variable factors were eliminated in the experimental work because by use of the ligature the arterial occlusion was a known factor. In the dog it would be undesirable to reduce coronary artery inflow by the arteriosclerotic process even if it were possible to do so. This study of coronary artery occlusion would not exist if it were not for the fact that controlled occlusion by the ligature was used. It is a fact that a surgical operation can be done on a normal dog heart, and sometime thereafter a coronary artery can be ligated completely and in one step, and the dog has a

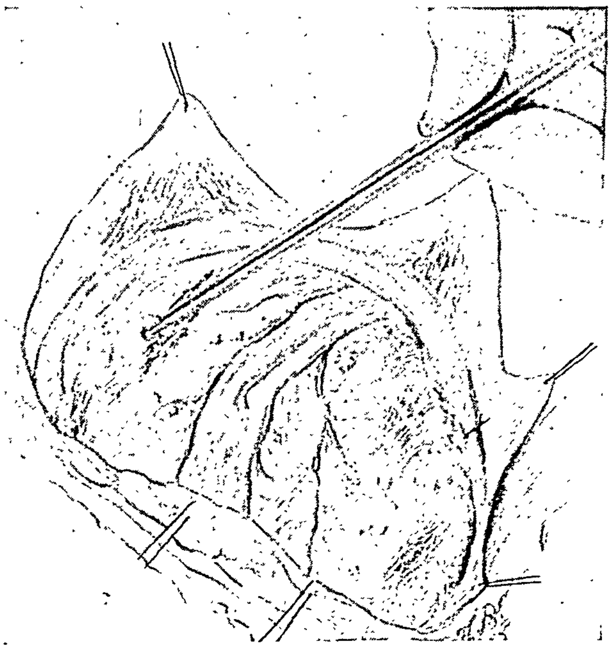

Fig. 12.—Sprinkling of an inflammatory agent (0.2 to 0.3 gm. coarsely ground asbestos) over the entire surface of heart.

better chance to continue to live than it would had the operation not been done.

It is desirable to present information on the patients concerning arterial occlusion and mortality subsequent to operation, but it is scarcely possible to do this with the data available at the present time. Our medical cardiologist, Dr. Bernard Brofman, is working on this subject, and our belief is that arterial occlusion occurs after operation and the clinical evidence is often not adequate to make a diagnosis. This is favorable for the operation. It is likewise our belief that the operation prolongs life, but to prove this statement on a statistical basis requires two identical groups of cases. Lindgren reported mortality in a group of 88 patients who were acceptable candidates for sympathectomy for angina pectoris, but the operation was not done in these patients because of nonmedical reasons.[9] The mortality was 17% the first year and 13% the second year, for a total of 30% for two years. These figures may be compared to our experiences, but the two groups probably are not strictly comparable. The operative and postoperative mortality with the number 1 operation in 75 patients was 6.6%. This mortality rate is lower than our previous figures. In the last 49 patients operated upon at Mount Sinai Hospital, Cleveland, the mortality was 2, or about 4%. The mortality in 136 patients occurring from the time of discharge from the hospital up to one year was 6.6% and in 83 patients from one year to two years was 4.8%. If these figures are added together the total operative and two year postoperative mortality is 11.4%, which is lower than Lindgren's figures without operation. We expect life to be prolonged by operation, and this is the most important purpose of our extensive studies on this subject. It is desirable to measure this aspect of the work by operating on alternate patients and determining mortality in both groups, but this is for the future.

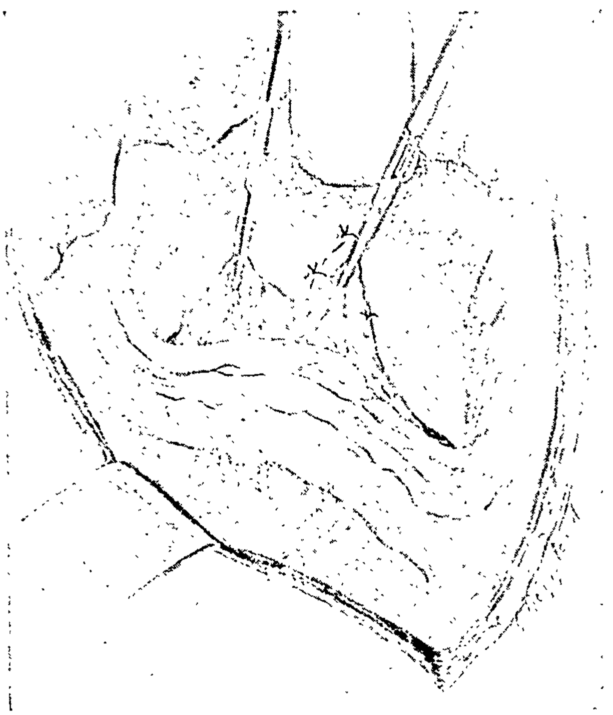

Fig. 13.—Pericardium partially closed. Mediastinal fat is used to cover the heart as much as possible. Here it is brought beneath the bridge of pericardium containing the pericardiacophrenic artery and vein. In most instances it is attached to the right border of this bridge of tissue.

SUMMARY AND CONCLUSIONS

Uniform distribution of oxygen to myocardium produces an electrically stable heart; lack of this uniformity produces an unstable heart. Differences in electrical potentials of the heart are produced by "oxygen differentials." The term "current of injury" is probably not correct. A uniformly cyanosed heart is not an injured or an unstable heart. With the number 1 operation for coronary artery disease, operative mortality has been reduced to 6.6%. The more important component of this so-called operative mortality is the disease rather than the operation. Operation relieves symptoms in 9 out of 10 patients. So far the trend of experience seems to indicate that operation prolongs life. Operation adds 282 cc. of blood per hour to ischemic myocardium, and this blood is present at the crisis of arterial occlusion. This is comparable to a transfusion of arterial blood into ischemic muscle. There is no experimental evidence to indicate that medical therapy adds or subtracts a single drop of blood to ischemic areas of myocardium. In view of this limitation the patient with coronary artery disease should be told there is a more effective treatment. Operation should be done early in the course of the disease before irreparable damage occurs in the myocardium.

DIFFERENTIAL DIAGNOSIS OF CHEST DISEASES

Andrew L. Banyai, M.D., Milwaukee

The problem of differential diagnosis of chest diseases may arise in medical practice in four ways. 1. Patients are seen by the physician because of symptoms referable to the chest. 2. Abnormal findings may be noted on routine chest x-ray examination on admission to general hospitals. 3. Abnormal chest findings are discovered on mass x-ray surveys and preemployment examinations. 4. Chest disease may be found in persons who are seen at periodic examinations on their own initiative or in groups, as in private industry and public institutions. The cardinal points of efficient diagnostic approach are: (1) accurate history (chronologic, environmental, occupational, and surgical), (2) thoracic and general physical examinations and correlation of pertinent findings to chest diseases, (3) interpretation of x-ray shadows in chest films, (4) expedient use of laboratory methods, and (5) adjunct diagnostic procedures. Symptoms that establish the first contact between patient and physician may serve, individually and collectively, as useful clues to considering appropriate means for correct diagnosis.

PULMONARY HEMORRHAGE

Expectoration of blood, particularly in large amounts, is often an alarming event. Assuming that one can rule out bleeding from peptic ulcer, esophageal varix, and the oropharynx, it is well to evaluate pulmonary hemorrhage in relation to the patient's age. Children, adolescents, and young adults should be scrutinized, first of all, for possible bronchiectasis, mitral stenosis, and tuberculosis. Persons 50 years of age or older, particularly men, should be studied for carcinoma of the lung and tuberculosis. Should this orientation fail, other possible sources of pulmonary hemorrhage should be explored. Some sources of pulmonary hemorrhage are given in the following four groups: (1) severe bronchitis (caused by infection, noxious fumes, gases and dusts, or allergens), benign or malignant tumors, lung abscess, bronchial ulcers, bronchial varicosities, broncholiths, and infestation with animal parasites; (2) cystic disease of the lung, pulmonary arteriovenous fistula, hereditary hemorrhagic telangiectasia, essential pulmonary hemosiderosis, and increased capillary fragility; (3) pulmonary infarction, myocardial failure with pulmonary congestion, sclerosis of the pulmonary artery, hypertension, and perforating aneurysm; and (4) aspirated foreign body, thoracic trauma, blood dyscrasias, perforation of abscess or tumor of adjacent organs and structures, and pulmonary manifestations of systemic diseases.

COUGH

Searching for the cause and origin of cough, one should consider affections of the respiratory tract and diseases of the heart. Respiratory diseases of this type include acute and chronic infections, allergic changes, and irritation of the mucous membrane by noxious fumes, gases, dusts, and tobacco smoke. Aspiration of a foreign body is usually associated with sudden gagging, choking, coughing, wheezing, and dyspnea. This episode may be followed by a symptom-free interval of one or more days and even months or years. Dislodgment of aspirated foreign bodies results in recurrence of these symptoms. There are a great many instances in which a history of aspiration is lacking, particularly in young children, in forgetful senile persons, and in cases when the accident took place under intense emotional tension or in unconscious states. Bronchospasm may provoke cough. It may be encountered not only in cases of allergic bronchial asthma but also in cases as the result of pulmonary infection, fibrosis, congestion (overt or latent), emphysema or irritation by aspirated foreign bodies, or broncholiths. Cough due to allergic bronchitis may precede asthmatic attacks by years. It may be easily mistaken for bronchitis caused by other factors. This type of cough may come on during the night only. Because of tenacious secretions, cough may be strenuous. Cough that is more pronounced at night should bring to mind heart failure, lung tumor (especially carcinoma), enlarged lymph nodes, and tumors of the mediastinum as possible provocative causes. In failure of the right ventricle of the heart, edema of the lower extremities decreases when the patient goes to bed. At the same time the lung becomes "water logged." An enlarged left auricle in long-standing mitral valve disease may exert pressure upon the left main bronchus and cause cough.

Cough occurring when the person changes position from erect to horizontal, stoops down, or bends over may signify spilling of exudate or foreign material from smaller into larger bronchi. Complaint of this sort may be heard from patients with bronchiectasis, infected lung cyst (congenital, dermoid, or parasitic), lung abscess, bronchopleural fistula, cardiospasm, and diverticulum of the esophagus. Cough on swallowing occurs in persons with developmental anomalies in the oropharynx, esophagotracheal, or esophagobronchial fistulas and in instances where there is a sensory or motor dysfunction of the laryngeal nerves. Increase in cough after meals is seen in persons with chronic lung disease. It is attributable to a reflex through which bronchial secretions are augmented in consequence of stimulation of the gastric sensory receptors of the vagus nerve. Recurrent episodes of cough in children should be scrutinized for allergy, bronchiectasis, tuberculosis, and aspirated foreign body. Children may have coughing spells after strenuous exercise. Their asthma may be mistaken for recurrent bronchitis or bronchopneumonia.

In cases of primary bronchogenic carcinoma, cough usually develops gradually. It may cause a change in the cough pattern of persons with "cigarette cough." It is persistent and difficult to control. There are some instances of lung cancer where the onset of cough is sudden and signalizes the presence of secondary lung ab-

---

Chairman's address, read before the Section on Diseases of the Chest at the 104th Annual Meeting of the American Medical Association, Atlantic City, June 8, 1955.

scess. On the other hand, cough may suddenly disappear with the development of atelectasis distal to the neoplasm. Unproductive cough is observed when its cause is outside of the lung, as in diseases of the upper respiratory tract (postnasal drip secondary to paranasal sinus infection, partial nasal obstruction, enlarged tonsils, elongated uvula, swelling of the mucosa of the pharynx, larynx, and trachea, and tumors that may be encountered in this region), enlarged lymph nodes and tumors of the mediastinum, aortic aneurysm, and diseases of the pleura and the diaphragm. Also, patients may complain of unproductive cough in the early stages of lung infection (bacterial, viral, rickettsial, and parasitic) when there are considerable mucosal congestion and formation of viscous exudate, moreover, in allergy and with neoplasms of the lung and adjacent structures. Paroxysmal cough (fits of coughing) is seen not only in cases of whooping cough but also in cases of bronchial asthma, allergic bronchitis, and fibrinous bronchitis; in some cases of chronic bronchitis; and in cases of acute pulmonary edema, lung abscess, fluid-containing cysts, bronchial fistula during periods of evacuation of inflammatory material, aspirated foreign bodies, and broncholiths.

PAIN IN THE CHEST

Pain is a common subjective signal of organic disease. Chest pain may originate from diseases of the pleura, lung and cardiovascular system, from pathological changes in the mediastinum, esophagus, trachea, diaphragm, chest wall, and abdominal organs, or from other miscellaneous causes. The site of pain in pleurisy usually coincides with the site of maximum involvement. Patients with diaphragmatic pleurisy may complain of pain in the shoulder region because of transmission of impulses from the sensory receptors of the phrenic nerve to the cervical cord and from here to the neck and shoulder. Also, in these cases one may note tenderness along the costal margin and in the epigastrium. In some instances extensive pleurisy may exist without pain. In diagnosing pleurisy one should not rely on roentgenograms alone. Pronounced friction sounds may be audible in some cases of pleurisy without demonstrable changes in the x-ray film. In the latter small pleural effusion may not be seen unless a roentgenogram of the chest is taken with the patient lying on the diseased side. In large pleural effusions the liver may be palpable from 2 to 3 cm. below the costal margin. Children may have vomiting with pleural effusion. In adults exploratory thoracocentesis is preferably done at the eighth or ninth interspace in the scapular line, in children at the site of greatest dulness of the percussion note. Infralobar (supradiaphragmatic) and interlobar pleural effusions occur more frequently than is generally realized. Bacteriological, chemical, cytological, and other laboratory studies are mandatory for establishing the etiology of pleural effusions. In tuberculous pleural effusions from 75 to 100% of the white blood cells are lymphocytes, except in early phases of the disease when neutrophilic leukocytes may predominate. Long-standing transudates, nontuberculous exudates, pleural effusion associated with Hodgkin's disease, and rheumatic fever may show a predominance of lymphocytes.

Clinically significant hydrothorax is most often the result of heart disease, but it also occurs as a complication of nephritis and as a complication of tumors of the lung, pleura, mediastinum, and diaphragm. Pleural transudate is a characteristic finding in Meigs' syndrome. The pleural effusion is secondary to peritoneal transudate, caused by a fibroma of the ovary, and reaches the pleural cavity by diffusion through the lymph channels of the diaphragm. Ascites starting from other abdominal and pelvic diseases may be associated with hydrothorax. In heart disease the effusion is more frequently on the right side than on the left side. This is attributed to pressure of the greatly enlarged right aurical upon the pulmonary veins. Possibly, the larger pleural surface of the right lung favors the penetration of transudate. Thoracic pain originating from the pleura may be caused by infarction, primary and metastatic neoplasms, silicosis, asbestosis, spontaneous pneumothorax, hemopneumothorax, chylothorax, trauma, and formation of bronchopleural fistula. In spontaneous pneumothorax and in tumors of the pleura, pain may be precordial and angina-like. Parenchymal and interstitial infections of the lung (lobar pneumonia, bronchopneumonia, disseminated forms of virus pneumonia, and lung abscess) may result in chest pain. In some of these instances pain may be retrosternal and oppressive in character. Bronchitis and bronchiectasis may be associated with chest pain. The latter is brought about by pressure of accumulated inflammatory exudate upon the bronchial mucosa. In some of these instances pain may be pronounced, but it is relieved by adequate bronchocatharsis. Bronchial ulceration caused by infection or new growth may provoke pain in the chest.

Tumors of the lung may lead to chest pain either by direct pressure or by bronchial occlusion followed by atelectasis and infection. Sudden massive atelectasis from any cause is likely to be associated with thoracic pain. Other possible causes of this symptom are pulmonary congestion, broncholiths, air embolism, arteriovenous fistula, interstitial emphysema, bronchospasm with retention of secretions, and pathological alterations associated with systemic diseases. In many instances pain is exaggerated on deep inspiration (ponopnea) or on coughing. In lung tumors the pain may radiate to the arm. The significance of pain resulting from cardiovascular diseases cannot be overemphasized. Depending upon the medical history and physical, x-ray, electrocardiographic, functional, and other clinical findings, the following conditions should be given due consideration: coronary artery disease, mitral stenosis, aortic stenosis, myocarditis, pericarditis, aortitis, aneurysm of the aorta, dissecting aneurysm, ruptured aorta, coarctation, hypertension (systemic or pulmonary), neurocirculatory asthenia, and abuse of nicotine and coffee.

Almost any mediastinal disease may cause retrosternal pain, including mediastinitis and enlarged hilar and paratracheal lymph nodes caused by tuberculosis, severe generalized infections, fungous disease, sarcoidosis, infectious mononucleosis, syphilis, silicosis, diseases of the hemopoietic system, and diseases associated with erythema nodosum. Pain in the chest may be caused by benign and malignant tumors of the mediastinum; intrathoracic, nontoxic, nodular goiter; mediastinal cyst and hernia; and perforation of the esophagus by a foreign body. Pain exhibited by patients with mediastinal tumors and intrathoracic goiter may be anginoid in character. Pneumomediastinum is likely to cause considerable chest pain together with dyspnea of various degrees.

Affections of the esophagus, with or without dysphagia are the sources of thoracic pain more frequently than generally realized. The discomfort varies from mild burning sensation to severe pain anteriorly or posteriorly. It may be localized in the midline or laterally. In some instances it is identical with anginal pain. In addition to esophagitis caused by infection or poisons, the cause of pain may be carcinoma or other tumors, foreign body, rupture, diverticulum, stricture, and megaesophagus. Anginoid pain may result from esophageal spasm at the cardia. Nonsphincteric esophageal spasm, between the upper and lower ends of this structure, may result in dull, or severe, shooting pain. Fluoroscopic examination, roentgenograms with contrast medium, and, if necessary, esophagoscopic examination reveal the nature of the disease. Hiatus hernia as a possible cause of pain in the chest is often overlooked. Pain originating from this source may be localized at the lower part of the chest, at the left costal margin, or in the scapular region. It is worse when the patient is lying down, particularly after heavy food intake. The pain may be angina-like, and it may radiate to the left shoulder and arm, but it is rarely provoked by physical exertion or by emotional distress. On the contrary, this type of substernal distress may be relieved at night by sitting up in bed or getting up and walking around. Diagnosis is established by roentgenograms of the esophagus with contrast medium with the patient in the Trendelenburg position and by other auxiliary x-ray methods. In standard chest x-ray film a curved linear density parallel to the left cardiac silhouette is suggestive of hiatus hernia. Awareness of this disease is of particular importance because of its increased incidence in advanced age and because mistaking it for heart disease implies faulty therapeutic management, uncalled for heart consciousness, and, possibly, loss of gainful occupation and needless invalidism.

Of other diseases that may cause pain in the chest, mention should be made of acute diaphragmitis (Joannides-Hedblom syndrome) and involvement of this muscle by trichinosis, in periarteritis nodosa, and in cases of benign and malignant tumors. Some patients with pseudohypertrophic emphysema of the lung complain of pain in the lower part of the chest. Most likely, the pain is attributable to hypoxia of the diaphragm and intercostal muscles. A great many diseases of the chest wall may cause pain that may be misinterpreted as originating from pulmonary or cardiovascular affections. In this category belong myositis, fibrositis, diseases of the interspinous ligaments, osteomyelitis, periostitis, and tumors or fracture of the cervical or thoracic vertebrae, the ribs, and the sternum. Moreover, one should keep in mind the possibility of herniation of an intervertebral disk in the cervical or upper thoracic spine, with pressure on the spinal cord, spinal arthritis, Tietze's syndrome, slipped costal cartilage, and suppurating intercostal lymph nodes. Herpes zoster may be associated with severe pain in the chest prior to its characteristic skin manifestations, thus simulating acute pleurisy. Mastitis, trauma, post-thoracotomy muscular imbalance, and spinal radiculitis are other possible sources of thoracic pain.

Pain originating from some of the abdominal organs may be referred to the chest through mediation of the major splanchnic nerves to the posterior root ganglions of the dorsal spine, anastomosis of branches of the superior mesenteric plexus and the phrenic nerve, or direct pressure upon the sensory nerve endings of the phrenic nerve at the lower surface of the diaphragm. Furthermore, it is known that lymph vessels of the gallbladder have connections to retrosternal and diaphragmatic lymphatics. Substernal pain simulating angina pectoris may be noted in diseases associated with distention of the biliary tract; in some cases of acute gastritis, gastric ulcer, duodenal ulcer, perigastritis, and periduodenitis; in distention of the stomach due to aerophagia; and in distention of the splenic flexure of the colon. Precordial pain may also result from pylorus spasm and pronounced gastric ptosis. In some of these instances pain may be referred to the neck, shoulder, and arm. In patients with peptic ulcer, thoracic pain may be exaggerated by coughing and it may be more pronounced at night.

Pain below the right scapula or in the right shoulder is of common occurrence in cholecystitis and cholelithiasis. Pancreatitis and carcinoma of the pancreas, hepatodiaphragmatic adhesions, sudden hepatomegaly due to congestion in failure of the right ventricle of the heart, liver abscess, and subdiaphragmatic abscess may cause pain in the lower part of the chest or in the shoulder. Acute and chronic appendicitis may be the source of pain in the right supraclavicular region. Also, in some of these instances pain may be elicited in this area by manual pressure at the right lower quadrant of the abdomen. In addition to an accurate clinical history, with special attention to the timetable of pain in relation to food intake, physical examination, electrocardiographic and x-ray studies, and other methods are necessary for correct diagnosis.

Thoracic discomfort varying from slight to severe pain may be encountered in other disorders. Precordial pain may be present in cases of hyperthyroidism, hypothyroidism, pernicious anemia, and severe secondary anemia. Pain may be referred to the chest in tumors of some of the cranial nerves, tumors of the base of the skull, neoplasms of the spinal cord and spinal nerves, supranumerary cervical rib, carotid sinus syndrome, and tabes dorsalis. Other diseases that may be associated with chest pain are scalenus anticus syndrome, epidemic pleurodynia (Bornholm disease), lead poisoning, hypoglycemia, thiamine chloride deficiency, and hyperventilation. In the subconscious mind of some individuals pain may serve as a disguised escape mechanism from distressing emotional or mental situations. Clarification of physical and x-ray findings in the aforementioned instances may require serologic, hematological, biochemical, metabolic, and other studies.

DYSPNEA

Dyspnea is regarded in most instances as a serious warning signal of disorders of the cardiorespiratory mechanism. Space does not permit a detailed consideration of dyspnea resulting from sudden occlusion of the air passages by an aspirated foreign body or of their gradual obstruction by neoplasm, goiter, aneurysm, cyst, and other mediastinal diseases. Severe thoracic trauma may interfere with normal respiration and circulation. Pulmonary ventilation may be gravely disturbed by poliomyelitis, myasthenia gravis, encephalitis, meningeal hemorrhage, and cerebellar tumors. Hemorrhagic, traumatic, and surgical shocks interfere with the normal rate of blood flow and cause dyspnea. Dyspnea may be the result of severe anemias and poisonings that disturb the transportation of oxygen to and utilization of oxygen by the tissues; it also can be caused by pressure of diaphragmatic hernia and by elevation of the diaphragm in ascites. Women may complain of dyspnea during the later part of pregnancy though the heart is normal.

In the symptomatology of dyspnea one should consider the possibility of sighing hyperventilation (hyperventilation syndrome), hyperventilation of nephritic and diabetic acidosis (central type of dyspnea), and shortness of breath due to pain in the chest. Special attention to the psyche of the patient may be of utmost importance, for anxiety, frustration, and other adverse psychogenic factors may cause subjective difficulty in breathing. The following conditions are common causes of dyspnea: infections and tumors of the lung and pleura, including various types of pneumonia; severe bronchitis; interstitial pneumonitis; atelectasis; extensive pulmonary fibrosis; congenital cystic disease of the lung; interstitial emphysema; pulmonary embolism; pulmonary hypertension; and pseudohypertrophic emphysema. Allergic bronchial asthma belongs in this category. Here dyspnea is attributable to bronchospasm, tenacious bronchial exudate that occludes the lower air passages, and consequent atelectasis and emphysema. Spontaneous pneumothorax and large pleural effusion represent loss of large respiratory areas of the lung and lead to dyspnea.

Pulmonary edema blocks the alveoli, thus interfering with oxygen and carbon dioxide exchange. Although it may result from inhalation of noxious fumes and gases, its most frequent source is failure of the left ventricle of the heart. Pulmonary congestion or edema from this source may be seen in the form of nocturnal cardiac asthma, evening dyspnea, dyspnea in the recumbent position, and exertional dyspnea. I have observed that in some patients with dyspnea on exertion, without basal rales on auscultation, prompt relief from this symptom was secured by digitalization and diuresis (latent pulmonary edema). Dyspnea may be observed in patients with paroxysmal auricular tachycardia, auricular fibrillation and fluttter, and pulmonary congestion due to mitral stenosis or to strain of the left ventricle resulting from acute glomerulonephritis. Another point that deserves special attention is the hitherto unrecognized high incidence of bronchospasm. As mentioned previously, it occurs in a great variety of lung diseases, such as allergy, infection, mechanical and chemical irritations of the air passages, pulmonary fibrosis, and emphysema. Experience has shown that bronchorelaxant drugs are bound to bring about salutary results in these cases.

CONCLUSIONS

Accurate diagnosis is the key to successful treatment of chest diseases. Thus, it is mandatory that the physician approach this problem with a wide orientation in medicine, an inquisitive mind, and sound logic. The welfare of the patient demands that the physician take full advantage of diagnostic aids derived from x-ray and laboratory studies. One should also avail himself of other diagnostic methods, such as skin testing, biopsy, bronchoscopy, and cardiorespiratory function tests as circumstances may require. It is inexcusable to omit a thorough physical examination.

PROBLEM OF ECZEMA

Ralph Bookman, M.D., Los Angeles

Among the major manifestations of allergic disease, eczema is a frequent problem in diagnosis and treatment. When the skin is the shock organ, it is as necessary to understand the important role of secondary changes as it is to recognize the allergic mechanism and the associated allergic factors. While a diagnosis of eczema is not characteristically difficult, the discovery of the etiological agents and actual management of the case can baffle the practitioner. This is derived partly from the persistence of certain ideas and practices that are contrary to observed facts and that disappoint those who attempt to apply them. With a knowledge of basic allergic principles and a common sense assessment of therapy, the disease should be less of a problem in etiology and its treatment, both symptomatic and specific, will become more successful.

The identification and limitations of eczema has been made difficult not only by a tendency to regard it as a skin disease but also by the use of many terms that confuse rather than clarify the condition. It is more accurate to regard the various superficial manifestations as different phases of a single process.[1] Of the many terms in use, "allergic" or "atopic dermatitis" is perhaps most descriptive but "eczema" has more historical support. The condition is not limited to childhood and is seen in every decade although it is not common in the aged.[2] Eczema is always bilateral and somewhat symmetrical. Not only is the classical flexural distribution seen in the bends of knees and elbows, but the exposed areas of the body are commonly affected. The face and neck and extremities may be partly or completely involved. Rarely,

however, do the lesions invade the hairy scalp or the palms or soles. Occasionally, the trunk can be the site of lesions but only in association with the other areas noted. The earliest manifestation of the disease is actually an urticarial wheal that is quickly masked and distorted.[3] Pruritus of a persistent, agonizing, and exacerbating character causes constant scratching and rubbing and a traumatic alteration of the skin that totally submerges the initial urticarial phase of the lesions. Upon the thin and insubstantial skin of the infant and younger child, this itching and rubbing produces erythema, then vesiculation, and finally exudation of serum from the edematous, involved areas. Crusting is naturally associated with this process. When the skin of the older child and adult is submitted to this same incessant scratching and rubbing, it becomes leathery and lichenified and exfoliates constantly. Many crusts are seen as are local thickenings where healing competes with repeated injury. During severe exacerbations of this older group, areas may develop the same characteristics as in the infantile type. Eczema is the same disease in all age groups. Despite the differences in the duration of the scratching and variations in the age of the skin and its reactions, all are responses to the same allergic stimuli.[2]

Differential diagnosis is not a problem as a rule. Such diseases as scabies, psoriasis, dermatitis venenata, and id reactions to fungus disease may have a similar appearance in some cases, but they also possess characteristic features that will identify them. Contact dermatitis has been mistakenly associated with eczema possibly because of the frequent use of the misleading synonym "contact eczema." Actually, there is a great difference between the two conditions. The contact lesion does not represent an allergic phenomenon except in the most strictly local sense. The basic difference in the vast majority of cases depends upon a characteristic location of the lesion in relation to some contactant and a history that also incriminates this contactant as a cause. Allergic investigation is of no value in contact dermatitis, and even patch tests are so frequently falsely positive or falsely negative [4] that the diagnosis often rests upon the location of the lesion, the clinical history, and avoidance of contact. Parenthetically, we have made it a practice in lesions of this type to seal them completely with adhesive tape when their location permits, such as the fingers or hand. Thus covered for several weeks, the involved area will show dramatic clearing in many instances.

DIAGNOSIS AND TREATMENT

The etiological diagnosis is the beginning of perplexity for many practitioners who attempt to care for the patient with eczema. Here is where the allergy history, the most valuable of diagnostic tools, can assemble pertinent facts and establish a continuity of events. In order to obtain a good allergy history, one must approach it free from prejudicial interpretation or anticipation of the facts one wishes to obtain. The statements of the patient must be accepted at face value and neither minimized nor emphasized to fit some preconceived theory. The most common failing in this category is to seek out and stress emotional factors. These patients are irritable and fatigued from sleepless nights of itching and scratching. Any psychoneurotic manifestations are understandably exaggerated, and any emotional upset will act as a trigger to start an exacerbation of the pruritus. This sequence of events is no more unusual in eczema than in any chronic disease state.[4]

It is important to seek evidence of other associated allergic phenomena in the history and physical examination. Not only does this lend support to the allergic character of the skin lesions, but the pattern of these other symptoms can give clues and relationships that may be obscured in the history of the skin lesions alone. Thus, an associated allergic rhinitis may have seasonal exacerbations suggesting that the skin lesions may also be partly the result of a pollen sensitivity. Both rhinitis and bronchial asthma are commonly seen, not only associated, but also alternating with the eczema over periods of months and years.[5] During quiescent or latent phases, it will be found that a blocked nose, rhinorrhea, or a cough and wheeze are present as persistent evidence of the allergic constitution. Infection also has an effect upon the course of eczema, and it has been observed that exacerbations will occur associated with the common bacterial infections. However, there is a pronounced tendency of the disease to subside or even temporarily disappear during the course of viral type disease, particularly the infectious exanthems.[6] Previous treatment of the eczema should be investigated, and it is often possible to relate exacerbations to a certain medicament or ascertain the failure of others. After seeing large numbers of these cases, one hears of remarkably few medicaments that have more than temporary value in the opinion of the patient who becomes a most critical judge as he continues to seek relief.

Skin Tests.—While great emphasis is given to the allergy history, it is equally important not to minimize the value of skin tests. Yet statements that disparage this procedure are seen, and many practitioners are unable to shake the doubt that such assertions create. Some believe that there is no value to skin testing [7] and that the patch test is the procedure of choice. They deny relationships with asthma and hay fever and believe that causal agents are rarely found or proved.[8] Statements of this character disappoint and confuse those who must encounter eczema in their practice and yet who lack the time and special experience to evaluate such concepts. Patch tests in eczema have been tried and discarded by all who have had experience with them.[9] The intimate association between eczema and respiratory allergy was described as early as 1881.[10] Finally, skin testing in the hands of those who regard it as a corroborative procedure that supports and further delineates the history becomes a potent factor in the ultimate long-range treatment of the causes of eczema. The skin test will always disappoint those who demand from it a final answer to etiology. There is no test in the field of medicine whose results are better than the physician who interprets them. This is particularly true of the skin test procedure in allergy. Variables such as false positive or negative reactions or potency of the testing materials can only be assessed by the physician who measures his test results in the light of a detailed history of the case.

Elimination Diet.—The widespread use of the elimination diet as a diagnostic procedure is an attempt to reduce allergy diagnosis to a relatively simple procedure. Considerable experience indicates that the elimination diet cannot be related to the known facts of allergic disease and therefore does not supply the answers being sought. Food as a cause of eczema plays no larger role than it does in other manifestations of allergic disease where inhalant factors such as pollen, feathers, animal danders, and dust are at least as important.[11] The infant is the exception to this generalization, but the simplicity of its diet makes elimination procedures superfluous. In infants and younger children, there is the danger of malnutrition that has occurred with the use of the elimination diet. Such a hazard is less desirable than a skin condition in a well-nourished child. In an analysis of the test results in 4,589 cases of allergic disease, Piness and Miller [12] concluded: "The insidious appeal of what superficially appears to be not only a practical but a simple method of diagnosis and treatment probably explains the popularity of the method. . . . [Since] the elimination diet does not eliminate . . . pollens from the air and epidermals, etc., from the environment how can we say that the patient is being assaulted by no offending substance. One is as important as the other and yet it is only foods that are eliminated by the elimination diet, and individuals who are sensitive to foods alone are extremely rare. Our statistics show only one person in one hundred as being sensitive to foods alone." This and similar observations [13] indicate that this procedure has little value in allergic diagnosis.

Drugs.—Complications are not commonly encountered in eczema. The involved areas are quite resistant to infection considering the character of the acute lesions. When infection does occur, it is usually of a staphylococcic nature with a pustular appearance. Response to systemic antibiotics in adequate and maintained dosage is prompt, but the condition will recur if treatment is not prolonged several days beyond the clinical evidence of improvement. The local use of antibiotics is less effective and more likely to cause skin reactions. Occasionally, particularly in children, the lesions will be refractory to usual treatment and a low-grade temperature with an elevated white blood cell count is discovered without known cause. Such patients also respond to antibiotics and must be considered as secondarily infected. A relatively rare complication of eczema, yet one with serious consequences, is Kaposi's varicelliform eruption, which is an involvement of the eczematous areas with the virus of herpes simplex or of vaccinia.[14] An obvious and oft-repeated corollary to a discussion of this condition is the warning never to vaccinate in the presence of eczema. Treatment consists of supportive care and administration of chlortetracycline (Aureomycin), which has been shown to be of some value.[15] Finally, the most important and above all the most common complication observed in eczema is the result of treatment.[16] Dermatitis medicamentosa can be the result of innumerable topically applied substances and will produce a superimposed rash that is not always clearly discernible from the underlying disease. In such instances, there is often marked improvement with the cessation of all medication. Systemic toxic reactions may occur from a medicament applied to large areas of skin, particularly in the infant, where considerable absorption of the product may occur in water-miscible creams and ointments.

Symptomatic treatment of the patient with eczema should be related to an understanding of the factors that potentiate the pruritus both in the skin and in the patient himself. In addition to the whealing and edema produced by allergic causes, the presence of crusts and scales as well as exposure of the lesions to the air [10] intensify the discomfort. Relief of these mechanical factors is accomplished by the use of epsom salt baths and boric acid ointment. The baths may be used three or four times daily and during the night if needed, and, after drying, the patient applies the boric ointment liberally to the involved areas. It will be found that the baths remove the crusts and scales, and the ointment both lubricates the skin and, by coating it, protects from exposure to air. Persistence of this simple regimen often brings comfort and rest. In addition to the skin, the patient and his family also require treatment. Explanation and calm reassurance have a more salutory effect than ill-advised predictions that had probably been disillusioning on some previous occasion. Mild sedation such as phenobarbital or chloral hydrate may be used for emotional instability, but large doses seem to increase discomfort. Sleep will occur with the relief of pruritus, not with narcosis. The development of corticotropin (ACTH) and the adrenal steroids have not mitigated the problem of treatment in eczema.[17] While dramatic clearing of the lesions will often occur, disappointments are frequent and the invariable recurrence after cessation of therapy may be of greater intensity than the original complaint. There is growing evidence of the dangers of these substances,[18] and their use in ointment form does not justify the high cost of covering large areas of skin. In the last analysis, it is still necessary and ultimately more fruitful to seek specific causes for eczema.

COMMENT

Allergic management represents an interpretation of the history, the physical examination, and skin test results into a program of elimination and specific desensitization. The patient must understand the physician's objectives and the reasons for his own cooperation. There is a limit to the exclusion of foods from the diet. Those that produce clinical reactions have probably been eliminated already. But the removal of a wide range of items based upon literal interpretation of skin test reactions is unrealistic. It is more reasonable to suggest constant rotation of a wide variety of foods, thus reducing the exposure of any one in particular. Naturally, there are many cases in which the selective character of the test results indicate the need to remove a number of foods from the diet. The inhalant group is equally and sometimes more important than foods. Desensitization to pollen must be calibrated to the season and the botanical peculiarity of a given area. In the case of environmental factors, removal of offending substances, particularly from the bedroom, can effectively reduce the patient's exposure especially at night when he needs it most. Desensitization is also indicated here, when the perennial nature of the problem must be understood and stressed. These are the broad principles of allergic management that, when intelligently practiced, will bring comfort and relief to the patient with eczema and gratification to his physician.

SUMMARY AND CONCLUSIONS

Eczema, or allergic dermatitis, is not a problem if it is regarded as a skin manifestation of allergy intensified by prolonged scratching. Symptomatic relief of itching is most effective when simple medication is used. Certain practices such as patch testing and elimination diets are found to be of little value in handling eczema. The ultimate goal of therapy is discovery and treatment of specific causes. These are determined by a careful history corroborated by skin testing.

THE GENERAL PRACTITIONER AND THE DISCHARGED MENTAL HOSPITAL PATIENT

Kenneth E. Appel, M.D.
and
Albert Scheflen, M.D., Philadelphia

One in every 12 United States citizens will spend some part of his life in a mental hospital. Each year over a quarter of a million mental patients are discharged to the community. Most of these discharged patients will require help. Under stresses some will relapse and some will develop psychosomatic illness; some will sit dejectedly on the communities' doorsteps; some will sullenly declare war on society; and some will adjust. Who is going to help these people? Continued outpatient therapy, social service follow-up, vocational rehabilitation programs, and family placement services exist. The discharged mental patient needs a society that will "count him in" through love, understanding, patience, and effort. Yet something more is needed. Knowledge and experience are needed to work with the mental patient. We shall have to depend upon physicians to furnish knowledge and to provide both individual treatment and community leadership. The psychiatrists, constituting about 4% of the medical profession, cannot do the job unaided. When patients leave our mental hospitals, the chances are 10 to 1 that they will seek the help of their family doctor in their readjustment to community living. What can the general practitioner do to help?

KNOWLEDGE THE PHYSICIAN NEEDS

A basic knowledge of clinical psychiatry is important. For centuries some physicians have been doing a good job of handling emotionally ill persons without any formal training in psychodynamics. Such physicians have had a feeling for and an awareness of the basic needs and drives of human beings. They have intuitively understood the motivations of behavior. The doctor should be able to recognize psychosis and suicidal, homicidal, or psychopathic tendencies. The ability to take a good history results often in sufficient information from past behavior to permit some predictions about the future. The physician should know what therapies the hospital or the specialist has to offer, so that he knows when to make referral and what he can expect from hospital or psychiatrist.

The physician needs to know his patient. This includes his assets and vulnerabilities; his life goals and how he goes about achieving them; what he fears, loves, and hates; and where his breaking point appears to be, what situations lead him into attack, flight, depression, or physiological upheaval. How satisfactory an adjustment can a patient make at his best? How dangerous is he at his worst? What helps him? Of course, every person is so complex that one never collects all these data, but observation and repeated conferences will gradually increase understanding.

Professor of Psychiatry and Chairman of the Department of Psychiatry, School of Medicine, University of Pennsylvania (Dr. Appel). Assistant Professor of Psychiatry, School of Medicine, Temple University (Dr. Scheflen).

Read before the Section on Nervous and Mental Diseases at the 104th Annual Meeting of the American Medical Association, Atlantic City, June 8, 1955.

There is a need to know the patient's environment and its interaction with him. What persons are important to him and how does he feel about them? Who can assist him? Who might he blame for his troubles if he then becomes paranoid? What persons gratify and which ones frustrate his needs? Some families through undue anxiety, intolerance, anger, or motives of gain may exaggerate the patient's symptoms and press for his recommitment. Others may be overprotective or blinded by similar traits in themselves, being unaware of the severity of the illness. The physician needs to understand the prejudices, intentions, feelings, and viewpoints of the important figures in the patient's life so that he can assess what difficulties or help they are furnishing. There should be appreciation of the demands that the patient's environment makes upon him. Sometimes complaints of patients, seemingly bizarre, have an unexpected degree of reality. Whenever serious crime is committed in a community there is often a tendency to blame discharged mental patients, though their records show that they commit fewer crimes than the average of the population. The physician should know about community services and what they can offer patients.

The physician needs knowledge of himself. He needs an awareness of his own attitudes and feelings toward mental illness in general and each patient individually. There is a need for self-examination as to how he feels about the patient and whether he tends to overidentify either with the patient or with the community when there is friction. Some physicians are extremely intolerant of overdependency, lack of responsibility, or some form of childish behavior. Some react very unfavorably to any expressions of hostility or negative feelings and quickly decide that the community should be relieved of such a person. A physician may think of mental hospitals as horrible "snake pits" and feel excessive degrees of pity and sympathy for the patient, thus delaying necessary rehospitalization. He may feel antagonism to members of the family or an employer of the patient and tend to foster the patient's rebelliousness and refusal to readjust. Some physicians are overfearful about the threats of their paranoid patients and fail to realize that, after successful treatment in a hospital, these patients are often grateful. Patients who exhibit primitive emotional behavior or transgress social codes tend to build up anxiety and hostility in us from which it is very difficult to dissociate ourselves. For these reasons the mentally ill were burned as witches during the Middle Ages, and we still tend to locate our mental hospitals in isolated communities far from our best facilities for diagnosis and treatment.

The problems of the novel, unconventional, or "different" patient need thought. Many persons are immediately threatened by newness or difference. Great men such as Copernicus, Darwin, and Freud threatened whole societies by their challenging ideas. In less significant ways the maturing patient may shed old patterns, become assertive, show constructive hostility toward his relatives, loosen up his miserliness, drop excessive inhibitions, and break old ties.

THE PHYSICIAN AS GUARDIAN OF THE PATIENT AND THE COMMUNITY

The emotionally ill patient may endanger himself in many ways. Suicide is spectacular but less common than many mundane hazards. Patients may make unreasonable expenditures of money and fall into debt. They may expose themselves to injury through impulsiveness, inattention, or self-destructive urges. The dischargee's behavior may threaten the community. Aggressive sexual perversions, dangerous management of automobiles or other machinery, a need to exploit others, paranoid campaigns, or assaultiveness are common problems. These, however, appear to be less dangerous than community opinion assumes. The patient may endanger the mental health of his wife and children.

The physician must assume a reasonable degree of responsibility for both patient and community. At times these interests may conflict. The easiest course is often to seek the readmission of the patient to the hospital, but this expedient may be a serious setback to the patient's rehabilitation, justifiable only when the risk is real. The calculated risk takes courage, but has its place in all phases of medicine. Resourcefulness often permits a better solution.

The threatening behavior may stop when realistic dangers or consequences are pointed out with kindliness. A simple, gentle interpretation of apparent motives for behavior may put an end to it. Sedation or reassurance may reduce pressure so that there is a greatly lessened need to discharge anxieties in undirected behavior. Less dangerous outlets may be substituted. Bowling, boxing, walking, competitive games, or work may be excellent channels for aggression. The resourceful physician may enlist the aid of family, social agencies, psychiatrists, and friends in solving problems that are sources of hostility or anxiety, to help find constructive new directions.

When recommitment or return to the hospital is necessary, it is to be hoped that the physician has the kind of human relationship with his patient that enables the patient to accept the proceedings even if they are painful. Such a relationship comes from genuine interest and understanding between doctor and patient. If the patient is uncooperative, he may have to be returned to the hospital under restraint. A physician's resorcefulness in such situations can devise gentle and nondramatic methods for accomplishing this. Large doses of sedatives may minimize the unpleasantness of the transfer. Reassurance, kindliness, and firm but friendly insistence are much better than lost tempers, deception, or physical force. The physician may have many conflicts about commitment. In deciding about recommitment the physician's own feelings may be the greatest threat to objectivity. Overidentification with the patient or with hostile members of his community has been mentioned. He may realistically or unrealistically consider the local hospital a "snake-pit" and the psychiatrist a "crack pot." A visit to the hospital might confirm the doctor's notion, but, on the other hand, he might be pleasantly surprised.

Outdated pessimistic attitudes about the incurability of mental illness handicapped many physicians and their patients' treatment. Throughout history the mentally ill have stirred anxiety and then hostility. We feel uncomfortable with the mental patient and cover our anxiety with jokes. One reason there is so little education, medical teaching, and remedial action in the field of mental health is that people feel anxious and prefer not to think about it. Our thinking is often limited by lifelong attitudes. There is a tendency quickly to recommit a disturbing fellow.

THE PHYSICIAN AS THERAPIST

The doctor offers the discharged mental patient the same medical services that he offers the community as a whole. The mental patient is obviously subject to any of the somatic illnesses, and there are reasons why the emotionally ill are even more prone to physical illness. It is well known that schizophrenic patients show considerable susceptibility to tuberculosis. Diseases of malnutrition and anemia are common among psychotic patients. It has long been known that certain psychosomatic conditions may have a reciprocal relationship with psychosis. The patient with an ulcer may lose his ulcer during a psychosis only to regain it when the psychosis has disappeared. This reciprocity is seen in skin disorders, asthma, colitis, and migraine. It is common that the discharged mental patient whose psychosis has been alleviated may return to the community to develop a psychosomatic disorder. On the other hand, schizophrenic, hypomanic, and certain other types of psychotic patients do not show exaggerated bodily symptoms in a hypochondriacal way but actually may exhibit a strong tendency to minimize or fail to mention physical complaints. The well-known hypochondriacal neurotic patient who repeatedly returns to the physician's office may lead some persons to generalize that somatic complaints are always characteristics of emotional disorders.

Experienced psychiatrists do not take every physical complaint lightly merely because a patient has a neurosis or a psychosis. Not infrequently mental symptoms are initial manifestations of an underlying organic disease. Notorious examples are brain tumors, carcinoma of the pancreas, and the blood dyscrasias.

After the patient is discharged from the hospital the community physician who is keeping in close touch with him may realize that new symptoms reveal the presence of an unsuspected illness. Some doctors, anxious and nonaccepting of emotional disorder, search incessantly for demonstrable physical pathology. Their patients are aware of this search and are glad to avoid the acceptance of a psychotherapeutic relationship and the discomfort of searching themselves for unwholesome attitudes and emotions. This makes proper treatment progressively more difficult or even impossible.

TREATMENT METHODS IN GENERAL PRACTICE

Establishing Interpersonal Relationships.—Establishment of interpersonal relationships, essential for mental health, requires interest or regard and understanding. There are several ways to give help. The physician may directly help the patient make contact with others, encourage him to do so, or advise him how relationships can be maintained. Most important, the physician himself should establish a warm, friendly relationship with the patient. Through this experience the patient learns how to establish relationship with others. A common factor in mental illnesses is the patient's tendency to become paralyzed with anxiety and search endlessly about the same stereotyped circles for some solution to his difficulty. The physician with calmness and reassurance can decrease this anxiety and encourage imagination and resourcefulness in finding new approaches and solutions. These can often be suggested but more solidly come from tactful and insightful questioning by the doctor. On occasion it is necessary that authoritarian firmness be used with patients, but, in general, suggestion and permitting the patient to turn ideas over and make his own decisions are the most effective approaches. The physician must be a good listener.

Relieving Anxiety.—Relief from anxiety, undue tension, and pain are necessary goals. A physical examination made with confidence, thoroughness, and sympathy can be of great therapeutic value. The discharged patient can be reassured that he is not having another psychotic episode. The simple statement that all of us at times have depressive thoughts, panicky feelings, antisocial fantasies, and feelings of anger, envy, or jealousy can bring great relief. Appropriately used sedation can interrupt vicious circles and allow a much needed chance to rest. This helps reorganization to take place. Amphetamine (Benzedrine) sulfate may sometimes lift a depression sufficiently to permit a new solution to be found. Sometimes tension can be reduced by suggesting some outlets for aggressiveness such as bowling, walking, boxing, bicycle riding, or swimming.

Abreaction.—Abreaction, or the ventilation of strong feelings, is of great therapeutic value. If the emotional roadblocks that have produced the piling up of such feelings are not modified, they will of course reaccumulate and cause further difficulty, but their mere ventilation may relieve the patient. Paralyzing anxiety or inhibition may be sufficiently reduced by this means so that new insight, new outlooks, and new solutions are forthcoming. Very common is the frustrated patient who is too passive or too dependent to express his resentment to anyone he knows. It accumulates. He feels he must handle it by extreme guardedness (tension) or by projecting it on others and feeling that they are hostile or by turning it against himself in guilt, self-criticism, self-punishment, and depression. If the doctor can permit some discharge of this feeling onto himself, the patient may be much relieved. To do this a satisfactory relationship must exist, and the doctor must make the patient feel that it is permissible and acceptable to bring out some of his anger. This may be done by eliciting why the patient has heretofore been unable to express his anger. When they feel acceptance in the releasing of emotions, patients have made a great stride forward. Children express aggression and anger at all ages. These are biological as well as social matters; they are natural and necessary. The mature parent expects and accepts these reactions and patiently, understandingly, and lovingly applies social restraint and training and encouragement, gradually facilitating growth and self-control. The unlucky child is hurt, ridiculed, and rejected for his biological and uncooperative urges. He grows reluctantly, with resentment, rejects himself, and expects society to reject him. He develops inferiority and guilt and feels alienated from himself and others. The parent has met the natural but unsocialized drives with anger and criticism instead of acceptance and guidance toward doing better. The physician can offer what the parent did not give.

Acceptance, of course, does not mean encouraging instinctual expressions beyond the age in which they are normal. The mental patient, in response to frustrations in his life, has gone backward to more childish, primitive, and archaic levels of behavior. He needs from the physician not the acceptance of his behavior but the acceptance of himself as a person. When he feels this he ceases to reject and hate himself. He can then find satisfaction in adult reality and repudiate his infantile motivations. He can begin to seek love and recognition for mature creativeness, giving, loving, and doing.

Achieving Balance.—The physician can help the patient achieve a balance between socially permissible satisfaction of basic human needs and reasonable social standards. In medicine we recognize the need for a balance between intake and output of fluids and calories. In psychology there is an analogous need to balance receiving and giving of love, praise, care, and pleasure. In mature living there is a balance between giving and receiving. The overdependent person can be brought to realize he can be loved only if he acts toward others in a way that evokes love, not by being sick, helpless, or martyred. On the other hand he may be unable to receive because he is afraid of being engulfed by his dependency or because he feels so guilty and unworthy. This may lead to renunciation of food, approval, sexual satisfaction, happiness, success, and even health.

Emotional depletion often results from a conflict between strong cravings and an overly strict conscience or set of ideals. The patient feels "I want but I ought not to want or have." When there is this conflict, the need for comforts, satisfactions, emotional support (the dependency needs) may produce shame, and self-denial may produce the anger of frustration. Anger results in guilt. Guilt and shame lead to self-punishment and renunciation of all satisfactions, which in turn produce more frustration and anger. This combination of dependency needs and shame leads to a need or even desire for illness or some other face-saving process or protection for dependency. This may be a mechanism in hypochondriasis.

Therapy requires opening avenues for reasonable satisfaction to reduce frustration on the one hand and on the other hand willingness on the part of the patient to be satisfied with realistic demands. Realistic means (1) what is reasonable to expect of an adult in our culture and (2) earned rewards for mature behavior and giving to others. In psychotherapy this may be accomplished by insight into guilt feelings and their purposelessness and the adoption of reasonable standards. The fear of dependent needs appears to be basic in psychosis. To protect himself the patient relegates these needs to the unconscious and may go to the other extreme of not asking for anything from anyone. This and the fear of his own anger may make him seclusive, ascetic, or coldly overcontrolled. He gets nothing from life. He may try substitute gratifications such as drugs, alcohol, overeating, or phantasy, or may feel justified in dependency only when physically ill. In some patients the conscience is temporarily abrogated, permitting some unacceptable or antisocial behavior. This is then followed by an unrelenting, intense self-punishment that is, however, ineffective in preventing a later recurrence of the same unacceptable behavior. Often the antisocial behavior is prompted largely by a rebellious need against the overly strict conscience.

Offering Information.—The physician can offer information. In addition to offering new solutions or ways to solution of conflict he can give simple explanations about psychology, about the nature of the human need for love, or about the reaction of hostility and how it can be handled.

Encouraging What Is Positive.—The physician needs to find and encourage what is positive in the patient. This involves encouraging and helping him to develop his natural talents by persistence, further education, or in any other way that occurs to him. Plans for constructive effort should not be discouraged. Successful psychotherapy cannot be done by merely pointing out what is negative. When the patient is discouraged, his achievements and abilities should be reviewed. Often the patient's self-defeating tendencies may cause him to relinquish progress along productive avenues, and these tendencies will then need to be interpreted. The patient needs help to find his assets and develop them.

Mediating Social Reintegration.—Finally, the physician can act as a mediator in social reintegration by (1) aiding the patient to find a place to live, a job, friends, and recreational opportunities; (2) dealing with unfavorable environmental factors; (3) cooperating with another physician if a psychotherapeutic program is being undertaken; and (4) educating the community in mental health and in constructive attitudes toward mental illness.

Except in unusual situations we would not consider psychotherapy successful unless the patient, if a man, had found gainful and useful employment; anchorage or a place to which he could belong; and friends, adequate relationships with other persons, and some philosophy of life. The patient can be helped in these things by a more active intervention on the part of the physician in his social milieu; at times this is the only method open to the doctor whose patient is unaccepting or unprepared for psychotherapy. The federal government, by a public law, provides for discharged mental patients on-the-job training, vocational guidance, job placement, books, tuition, transportation, and all other things necessary to prepare the dischargee for a gainful economic existence. The physician needs to be acquainted with these facilities. Sometimes it may be necessary to provide foster home placement or family care for the returning patient if his own family has disintegrated, lost interest in him, or demonstrated themselves incompatible with him. At times the physician can talk to employers, giving them some awareness of the patient's problems and helping them decide upon a suitable niche in a factory or business.

One of the commonest problems is to aid the family in adjusting to the patient. Sometimes the physician serves not as psychotherapist but as an assistant or catalyst in connection with the patient's psychotherapy with someone else. This may require suppression of his own doubts, disapproval, or antagonism to the other therapist. On the psychiatrist's part it necessitates close collaboration, explanation, and interchange of ideas so that the physician may understand the goals and procedures. A discharged mental patient may have therapeutic ties to some physician at the hospital or sometimes just to the hospital itself, standing in his mind as a symbol for protection, health, and understanding. A physician who is aware of this relationship may preserve it and utilize it to the patient's advantage. A person may find it difficult to deal with the hostilities that build up toward his marriage partner. The most well-meaning wife may be distressed to find her paranoid husband constantly suspicious of her sexual fidelity. The physician can sometimes explain the patient to the family and achieve for him a greater degree of tolerance and acceptance. At other times he may find it necessary to advise them to treat the patient as a normal citizen rather than to overprotect or pamper him. Sometimes joint conferences between the patient, the physician, and the family are helpful in bringing to the surface unfavorable attitudes and working them out.

Often the community attitude is a source of considerable frustration and pain to the discharged patient. He may be met with distrust, suspicion, avoidance, fear, or well-meant oversolicitousness. There are so many existing misconceptions about mental illness that need to be dispelled. As physicians, this is our responsibility. The public must be educated to dispel notions that psychiatric illness is always caused by heredity, overwork, or masturbation, or that daydreaming or leading a "bad" life per se cause mental breakdown. In the minds of many there is still a stigma attached to mental illness, and many persons still feel that the mental patient has only to "shake out of it" or "forget it." Many states have excellent pamphlets or films explaining the basic principles of mental health. It is hoped that in the future the physician will accept increasing responsibility to attend parent-teacher, church, and other civic meetings where he will have an opportunity to bring correct and accurate information about mental illness before the public. This not only will aid in the rehabilitation and social reintegration of the discharged patient but will be of immeasurable value in prophylaxis for those in the community who have not yet been to a mental hospital.

SUMMARY AND CONCLUSIONS

Comprehensive medicine includes treatment of the patient as a person as well as of his cells and concern with his emotional instabilities as well as his chemical equilibrium. The patient is not an isolated object for physical and laboratory study but a psychophysiological organism reacting in a social context. Family, job, and friend relationships may be guided by the alert physician, thus helping the preservation of health and the prevention of illness or its recurrence. Social and psychological factors are important in the salvaging of the patient who has been in a mental hospital. The family doctor often has a greater opportunity in helping patients maintain mental health than does the psychiatrist. Three points should be emphasized: 1. Psychiatry must move out of the mental hospitals into the community. 2. The future general practitioner will practice more and more psychiatry. 3. There are areas and methods in which the general practitioner can function effectively in emotional and psychiatric problems.

PAIN IN THE NECK AND SHOULDER, COMMON CAUSES AND RESPONSE TO THERAPY

Edward M. Krusen, M.D., Dallas, Texas

This report is based on a study of 800 patients with complaints of pain in the neck and shoulders and headaches, classified as "cervical syndromes." Patients having this particular type of complaint were studied because, although their problem is common, I feel that such patients are often not properly handled in both diagnosis and treatment. Frequently these patients are told there is nothing wrong with them because there are no marked x-ray or neurological findings. However, when the condition persists or progresses after a period of weeks or months or even years, everything from herniation of the nucleus pulposus in the neck to brain tumor is considered; and the patients are submitted to a multitude of tests, including myelograms, arteriograms, pneumoencephalograms, electroencephalograms, and ventriculograms. Rarely does anyone take the time to palpate the neck muscles or check range of motion of the neck before making tests. Certainly negative tests are of help in reassurance of the patient, but one wonders if they are necessary in many instances. For example, in my experience proved herniation of the nucleus pulposus in the neck comprises only a very small percentage of cervical problems.

COMMON SYMPTOMS AND FINDINGS

Symptoms and findings, with certain exceptions to be mentioned, were remarkably similar for all patients. As already mentioned the most common symptoms in this entire series were neck and shoulder pain and headaches. These were not necessarily associated. Headache was usually occipital but often involved temporal or parietal regions. It could be constant or occur in sharp twinges. Pain, paresthesia, weakness, and sensory changes in the arm and hand were also common symp-

toms. Less common were face pain, earache, blurring of vision, dizziness, and chest pain. Often definite psychogenic symptoms were present, such as globus hystericus, gastric upset, fainting spells, and a general anxiety state.

Findings usually included tense neck muscles, with limitation of rotation, lateral bending, and flexion. Tender areas were present in a high percentage of cases and were either nodular or in the form of rigid strands. X-rays frequently showed reversal of the normal lordotic curve with limitation of motion of a portion of the cervical spine and often gave the appearance of a subluxation. Some physicians have a tendency to overemphasize these x-ray findings and treat the patient by rigid immobilization in a collar or brace. In my experience this serves only to fix the condition in the patient's mind, and, although it may give temporary relief, compounds the problem of treatment when it becomes necessary to overcome the effects of prolonged immobilization.

ANALYSIS OF CASES

At first glance, all patients fell into one of two main groups: those with a history of relatable injury (328 patients) and those without injury (472 patients). The group with relatable injury was broken down according to four types of injury or accident. 1. One hundred thirty-nine patients received injuries in auto accidents. These injuries usually occurred when the patient was in a stationary car that was hit from the rear, the resulting whiplash motion causing strain of the patient's neck muscles. 2. Ninety-four patients received direct injuries to the head and neck. The majority of these injuries were sustained while the patient was either at work or engaged in sports activities. 3. Forty-nine patients were injured in falls. The greatest number of such injuries were found among construction workers who fell off scaffolds at varying heights. 4. Forty-six patients received indirect injuries. These were caused in numerous ways, often quite bizarre. For example, one lady caught the feather of her hat in a door, one man hurt his neck when his finger was yanked, and another was butted by a ram when he was bending over.

The time elapsing between injury and beginning of treatment varied from one day to several years. Many patients gave a long history of mild intermittent pains that were greatly aggravated by the injury. I feel that the discomforts complained of were not necessarily caused by the injury in all cases, but in each case the patient was convinced that the injury was responsible. Most patients in this group were those eligible for compensation insurance payments. Many others had complaints with definite psychogenic features after injury. An extreme example is that of a woman who developed headaches, with no physical basis, after she was beaten over the head by her husband. It was interesting but not too surprising to find that in this entire group of 328 patients, only 57, or 17%, had associated demonstrable injuries such as fractures.

The 472 patients without history of injury were divided into five groups: 1. Eighty-eight patients had acute cervical fibrositis or myositis. The typical history in this type of case was one of cervical symptoms occurring only a short time before treatment was started. Frequently there was a drawing of the head to one side, usually described as a "crick in the neck" by the patient. Results of treatment in this group will be discussed separately from results in the other groups, since treatment time and prognosis were found to be entirely different from all the others. 2. Thirty patients had advanced cervical osteoarthritis. This group included only patients with appreciable hypertrophic spurring of the vertebra and narrowing of the intervertebral disks as revealed by x-ray. Most of these patients had radicular symptoms aggravated by extension of the neck. Obviously, this group would have been much larger if all patients with minimal osteoarthritis had been included. 3. Thirteen patients suffered from scalenus syndrome. The main complaint in this group of patients was paresthesia and pain along the ulnar aspect of one or both arms, with varying degrees of cervical symptoms Some had typical cervical ribs. Scalenus maneuvers were positive in all cases given a diminution of pulse on turning of the head to the unaffected side or on downward pressure on the arm. 4. Twenty-four patients had a herniation of the nucleus pulposus in the neck. This group included only those patients having symptoms typical of the disorder accompanied by demonstrable organic findings, such as weakness, atrophy, sensory changes of radicular type, reflex changes if the appropriate dermatome was involved, and preferably changes in the myelogram. These objective changes were considered of paramount importance in making a definite diagnosis. Pain and paresthesia down the arm associated with limitation of neck motion, cough and sneeze effect, functional weakness, and sensory changes were found not to be pathognomonic of herniation. When myelograms were obtained in such patients for compensation claim purposes, many were found to be negative. Therefore, these patients were included elsewhere and not considered as a part of this group. 5. Three hundred seventeen patients had "tension neck." This was by far the largest group in the entire series. In these patients typical cervical symptoms were associated with environmental factors producing tension. No attempt was made to psychoanalyze the patients, but many facts were volunteered by the patient or discovered on routine questioning.

DISTRIBUTION BY AGE AND SEX

Distribution by age is shown in figure 1. The distribution curves were very similar for injury and noninjury groups, with a definite sharp peak between 30 and 50 years of age. As a matter of fact, 57% of all patients in the series were in their 30's or 40's. Distribution by sex is shown for the main groups in figure 2. Roughly, 60% of the total group were women and 40% were men. In the injury group, there were more men (55%) than women (45%). This was especially true for direct injuries, which involved over twice as many men as women. Auto accidents were the only type of injury that included more women than men. In contrast, in the noninjury group, 70% were women and only 30% men. This difference was most marked in the tension group, where women outnumbered men by more than three to one.

TREATMENT

Methods.—Treatment for cervical syndrome in general consisted of the application of heat, usually shortwave or microwave diathermy for 30 minutes, deep stroking and kneading massage, and, if tolerated, frictional massage. Except in the very acute cases, this was followed by vertical traction in a Sayre head sling according to the method of Hanflig,[1] which combines traction for one to three minutes with gentle manual rotation starting with approximately 30 lb. and with gradually increased amounts. All patients were given supervised active neck exercises. Particular stress was placed on rotation and lateral bending, with avoidance of extension. In addition, some patients received stimulation by a tetanizing current from a low-voltage stimulator in an effort to relax the tense neck muscles.

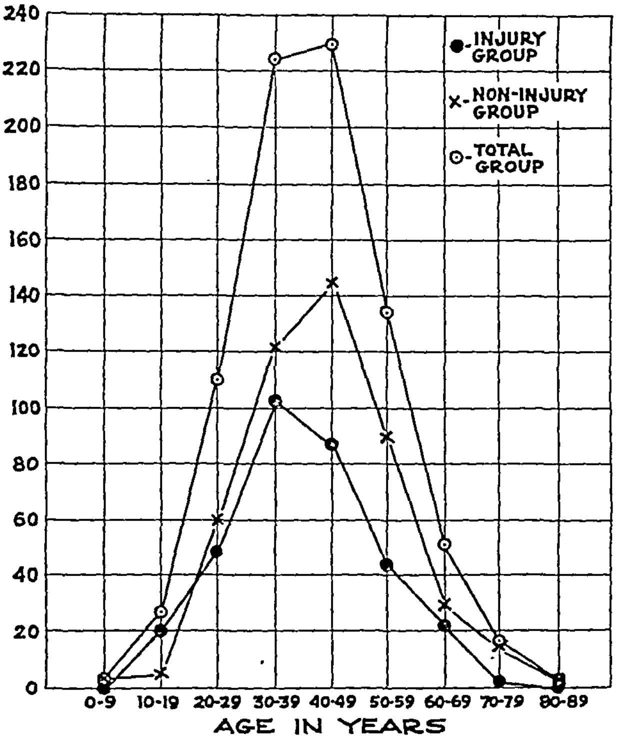

Fig. 1.—Distribution by age, showing numbers of patients in each decade for the main groups, of those having cervical disorders.

Evaluation.—Results were analyzed according to the degree of improvement in relation to the type of case, to the duration of the complaint before treatment, and to the duration of treatment. Average treatment times were also determined. Degree of improvement was defined in one of three ways: (1) good improvement, requiring marked or complete relief of symptoms with corresponding improvement in objective findings, (2) moderate improvement, signifying a variable amount of subjective relief but a definite change in objective findings; and (3) no improvement. A number of patients in each group of this series were not available for evaluation of final results. These included patients sent to the physiatrist primarily for diagnostic or disability evaluation, persons instructed in home treatment, and patients who discontinued treatment on their own before evaluation could be made. These cases were omitted from the statistical analysis to avoid confusion.

Improvement in Relation to Type of Involvement.—The degrees of improvement for the main groups are shown in figure 3. When the group with acute fibrositis was analyzed separately, the results for the remaining noninjury group were remarkably similar to those of the injury group. In the injury group 40.3% showed good improvement, 47.1% moderate improvement, and 12.6%, no improvement. In the noninjury group, 41.9% made good improvement, 38.5%, moderate improvement, and 19.6% no improvement. Results for the subdivision by specific complaint of these two main groups of patients except those given a diagnosis of fibrositis were essentially similar to these averages. They were analyzed individually, but the figures are not included here because some of the groups were too small to be significant. In marked contrast to approximately 40% good improvement in these groups, there was 90.9% good improvement in the group with fibrositis. The percentages for moderate improvement and

no improvement were correspondingly lower than in the other groups: moderate improvement, 7.3%, and no improvement 1.8%.

Average Treatment Duration.—Determination of the average time of treatment further demonstrated this difference in results. For the injury group, treatment time varied from a few days to over one year. Average treatment time was four to five weeks, and mean treatment time was three to four weeks. By the end of five weeks, 68.4% of patients had been dismissed. For the noninjury group, treatment time varied from a few days to 34 weeks. Average treatment time was three to four weeks, mean treatment time two to three weeks. By the end of four weeks, 75.4% of patients had been dismissed. For the group with acute fibrositis, duration of treatment was measured by individual treatments rather than in weeks. Treatment time varied from 1 to 29 treatments. Average treatment time was 7.7 treatments; mean treatment time was 5 treatments. Sixty-two per cent of patients were dismissed by the end of eight treatments.

Improvement in Relation to Duration of Complaint.—The length of time elapsing from the onset of the complaint until start of treatment had minimal effect on the degree of improvement. Contrary to our expectation, there was no striking difference in results. Improvement was slightly better in the group treated less than one month after onset than in those treated from one month to one year later; results in the group in which treatment was started over one year later were slightly inferior. Patients with acute fibrositis are not included here because of the short duration of complaint.

Improvement in Relation to Duration of Treatment.—The effect of the duration of treatment on the degree of improvement was also insignificant. Again, there was no marked difference in results. There seemed to be no optimal treatment time. The percentages of the different degrees of improvement obtained in later weeks were quite similar to those obtained for the first few weeks. The group with acute fibrositis is not included in this analysis because of the short treatment time.

COMMENT

One of the most striking findings in this study was the dramatic response of patients with acute fibrositis to only a few treatments. This fact must be kept in mind by anyone evaluating methods of treatment for cervical problems. The response of these patients to simple conservative measures is so prompt that it will upset results of studies of treatment of cervical disorders unless patients with this condition are considered as a separate entity. I feel that results for this group would probably have been even better if those patients who discontinued treatment without consultation could also have been included in the study.

I was surprised to find a marked similarity between the group of patients who had been injured and those who had no history of injury. It must be remembered that in private hospitals these latter patients had to pay their own treatment fees, while most of the former were being compensated. The results obtained strengthen my belief that the one factor common to both groups was tension and that an injury was often the precipitation factor producing or aggravating a tension state. A vital factor in the treatment of these patients that should be mentioned is an explanation of the mechanism of the pain. The idea that muscle tension from any cause produces pain and pain in turn produces muscle tension is often reassuring to the patients and helpful in their understanding of treatment procedures.

From the standpoint of prognosis, one cannot promise a patient with a cervical problem complete cure, although one can hope for considerable relief. From a compensation standpoint, there frequently remains some degree of permanent disability. However, many of these patients can be kept quite comfortable by intermittent professional physical therapy.

SUMMARY

Eight hundred cases of complaints of pain in the neck and shoulders, classified as "cervical syndrome" were broken down into various entities and analyzed according to age, sex, and results of treatment. Over half of all patients were between 30 and 50 years of age; 60% were women and 40% men. Acute fibrositis was found to be a separate and distinct category, with over 90% of patients showing good improvement and 7% moderate improvement, with an average treatment time of 7.7 treatments. Results for injury and noninjury groups were similar to each other, with approximately 40% and 42% of patients making good improvement and 47% and 39% moderate improvement respectively. The injury group had an average treatment time of from four to five weeks, while the noninjury group had an average treatment time of three to four weeks. Only a slight difference was found in the degree of improvement as a result of treatment of patients having complaints of varying duration before treatment was started. No significant difference was found in the degree of final improvement of patients needing treatment of varying durations, and no optimal treatment time could be determined.

Lower Nephron Nephrosis.—Tubular degeneration of the kidney has been popularly called lower nephron nephrosis. Often it has been spoken of as renal shutdown or acute renal failure. The clinical manifestation of tubular degeneration is signalized by oliguria or anuria and it is thought to be associated with an electrolyte imbalance. Hardaway refers to three phases of lower nephron nephrosis in illustrating a case. These phases are oliguria, diuresis and final recovery. He mentions that during the phase of oliguria the tubular cells are so damaged that all of the glomerular filtrate leaks into the interstitial spaces where it is reabsorbed; therefore, there is no infiltrate remaining to be excreted from the kidney. This period of oliguria lasts about seven days. The tubular cells then begin to recover and although they are water-tight, allowing the glomerular filtrate to pass out of the kidney, they have little absorptive power and little excretion function and consequently electrolytes are lost during the phase of diuresis. This is associated with a fixed specific gravity of the urine corresponding to the specific gravity of the glomerular filtrate. The third phase is that of recovery in which the kidneys resume their normal function.—C. O. Rice, M.D., and J. H. Strickler, M.D., Lower Nephron Nephrosis: II. The Function of the Kidney When Tubular Degeneration Exists, *The American Journal of Surgery*, October, 1955.

FURTHER EVALUATION OF HEATING BY MICROWAVES AND BY INFRARED AS USED CLINICALLY

Gordon M. Martin, M.D.
and
J. F. Herrick, Ph.D., Rochester, Minn.

Although a number of basic studies of the heating effects of infrared energy and diathermy have been made, there still remains considerable confusion regarding the comparative effectiveness of various sources of heat on human tissue. Infrared energy for radiant heating has been used for many years. The infrared generators are safe, simple to use, and inexpensive and are known to provide effective heating of at least the more superficial tissues. During the last 25 years physicians have followed with interest the development of various types of generators of high-frequency electromagnetic energy (diathermy equipment) for heating tissues at relatively greater depths than can be effectively heated with infrared. Diathermy machines have been expensive, more difficult to use, and, if improperly used, fraught with some danger of burns and discomfort. Since it has been shown that the temperature in muscular tissue can be raised significantly with a 20 minute application of infrared energy [1] as well as with diathermy, one might be inclined to conclude that infrared energy may be as effective as some types of diathermy. Likewise, on the basis of certain theoretical considerations and some experimental data, it has been stated [2] that microwave apparatus operating at 2,450 megacycles will not provide a significantly greater increase of temperature in deep tissue than will infrared.

In order to clarify certain points regarding the effectiveness of infrared and of microwave diathermy as used clinically we have made a comparative study of the heating of deep human muscle tissue by these two types of energy. The measurements of heating were made in the quadriceps femoris muscle of normal individuals according to procedures used in evaluating diathermy equipment for the Council on Physical Medicine and Rehabilitation of the American Medical Association. Certain standards were established by this Council for heating of deep tissue by a diathermy machine in order for it to be rated as acceptable.[3] The Council required that such a machine must be able to develop a temperature of 40 C (104 F) at the end of 20 minutes in the deep tissues of the quadriceps muscle on the anterior part of the human thigh. In 1947, the first commercial microwave-diathermy machine was tested under the auspices of the Council and it satisfactorily met these requirements. In 1954, two commercial models of microwave-diathermy generators were made available to us for further study. The heating effects of these two commercial generators have been compared with three standard sources of infrared radiation.

RESULTS OF STUDIES WITH MICROWAVE GENERATORS

The heating effects of two microwave-diathermy generators using three standard directors, namely A, B, and C, were studied. The frequency of these generators was 2,450 megacycles with a wave length of 12.2 cm. in air. This is one of the microwave frequencies allocated by the Federal Communications Commission for medical equipment. Twelve normal persons were used as subjects. Temperatures were measured by means of a thermocouple in a 20 gauge needle. This was inserted into the quadriceps muscle to a depth of 5 cm. (about 2 in.) from the skin surface, and temperatures were recorded before and immediately after a heating period of 20 minutes. The observations of temperature were made as nearly as possible under the region where the radiation of energy by the microwave directors was maximal. The output of the machines was varied according to the maximal comfortable tolerance of the patient, which is the usual criterion for clinical dosage. Energies from 50 to 100% of the maximal output of the machines were used. Directors were placed at a standard distance of 5 cm. from the skin. Six observations were made with each director of each machine, resulting in a total of 36 tests. The results of the changes in temperature are recorded in tables 1 and 2.

Consistent readings of 40 C (104 F) or higher were obtained in the quadriceps muscle at a depth of 5 cm. Previous studies on the heating effects of microwave diathermy in human muscle reported by Gersten and associates [4] utilized temperature measurements made at depths of 1.5 cm. in the volar aspect of the forearm of normal persons. These observations were made in muscle with relatively little overlying subcutaneous fat. Since it is considered that the amount of subcutaneous fatty tissue may greatly modify or limit the heating of the deeper muscles, it was interesting to note that consistent temperature increases ranging from three to five degrees (centigrade) could be obtained in muscles beneath layers of subcutaneous fatty tissue of varying thicknesses. Estimates of the thickness of skin and subcutaneous tissue were made in a number of subjects by means of soft-tissue roentgenograms in which the distance from the skin to the anterior surface of the quadriceps muscle could be determined approximately. The thickness of skin and subcutaneous tissue over the quadriceps muscle varied from 4 to 25 mm.

In the subjects in whom the maximal comfortable tolerance required that the output of the machine be maintained at 50% of maximum, rises of temperature were obtained that were comparable to the rises noted in subjects for whom the output was maintained at 80 to 100% of maximum. Gersten and his associates[4] studied the temperatures at the end of five-minute periods of heating with microwave diathermy and showed that a substantial rise in temperature occurred by the end of the first five minutes of heating. This early rise in temperature of the deep tissues indicates a primary type of heating with penetration of microwaves into the muscle. He noted that the temperature then increased slightly for 10 to 15 minutes to a maximum, which occurred usually between 15 and 20 minutes after the heating was started, and then decreased if the heating was continued to 30 minutes or longer.

RESULTS OF STUDIES WITH INFRARED GENERATORS

In a study of the heating effects of three commonly used sources of infrared energy for comparison with the effects of microwave diathermy, observations were made of the temperature in the quadriceps muscle at a depth of 5 cm. from the skin surface before and after 20-minute applications of infrared radiation. The three sources of infrared energy used were (1) a 250 watt reflector heat bulb applied at distances of 35 to 40 cm. (about 14 to 16 in.), (2) a 300 watt, ordinary frosted tungsten-filament bulb with a reflector applied at a distance of about 35 cm. (14 in.), and (3) a 450 watt carborundum-rod unit applied at a distance of 90 cm. (about 36 in.). The first two units are considered to be sources of near or short infrared energy and the carborundum-rod unit a source of far or long infrared radiation. The distance from the skin to the source of infrared radiation was based on the maximal comfortable tolerance of the patient. Temperatures of the deep tissue of the thigh indicated rises of a maximum of one degree (centigrade) in a series of normal subjects tested with the three sources of infrared (table 3). These studies were conducted in a room in which the temperature and humidity were controlled (80 F and 40% humidity).

Table 2.—*Summary of Changes in Temperature (Degrees Centigrade) with Microwave Diathermy at a Depth of Five Centimeters in the Quadriceps Femoris Muscle with Twenty-Minute Exposure*

* 40 C = 104 F.

† Rise of 4.3 degrees (centigrade) = rise of 7.7 degrees (Fahrenheit).

It is well known that the major amount of the infrared energy is absorbed in the first few millimeters of skin and subcutaneous tissue and that heating of deeper subcutaneous tissue and muscular tissue occurs secondarily. Gersten has shown that this type of secondary heating produces an almost linear increase in temperatures in the subcutaneous and muscular tissues over a period of 15 minutes when the infrared energy was applied over the volar aspect of the human forearm. Although in our study slight rises of temperature occurred in the muscular layers following the use of infrared radiation, certainly the degree of heating at depth is extremely limited and one can predict with some certainty that the rise of temperature at a depth of 5 cm. will be almost negligible. Our data showed that the highest rise in temperature observed in the deep thigh muscles was one degree (centigrade). These observations are in agreement with those of Sweeney and associates,[5] who found rises of less than one degree (centigrade) in muscular tissue of the thigh and buttock at a depth of 4.5 cm. and noted no significant differences in heating between the carborundum-rod units and the luminous sources of infrared energy. Likewise, Murphy and associates[6] showed no significant deeper heating with infrared radiation in experimental animals. These observations with infrared radiation are in marked contrast to our observations with microwave diathermy.

4	0.4	0.8	0
5	0	0.1	0.1
6	0.4	0.4	0.6
7	0.5	0.5	0.3

CONCLUSIONS

Microwave diathermy at 2,450 megacycles consistently raised the temperature deep in the quadriceps muscle to levels of more than 40 C (104 F) when applied for 20 minutes with the usual clinical techniques and dosages. Infrared radiation derived from three standard sources did not produce consistently significant elevations of temperature in the quadriceps muscle at a depth of 5 cm. from the skin surface. It is possible that other frequencies of microwave energy may be more effective than the presently used 2,450 megacycles in heating the muscles at deeper levels. However, at the present time, this frequency is certainly providing a suitable source of heat for producing significant increases in temperature in the deep muscular tissues of human subjects.

CLINICAL NOTES

ESCHERICHIA COLI MENINGITIS IN FIVE-DAY-OLD INFANT

REPORT OF A CASE WITH COMPLETE RECOVERY

H. Samson Gordon, M.D.
and
Julius Aronow, M.D., Chicago

Meningitis is uncommon during the first weeks of life. The mortality incidence of meningitis has changed for the better as a consequence of the introduction and availability of newer and more effective antibiotics, such as chlortetracycline (Aureomycin), oxytetracycline (Terramycin), and chloramphenicol (Chloromycetin). By way of example, before the advent of these antibiotics, of 74 infants less than 2 weeks of age with primary bacterial meningitis, only 7 survived.[1] The morbidity incidence, in the form of impaired cerebral function as a result of meningitis, persists.[2] The high morbidity is partly attributable to poor resistance of the infant to infection and partly to delayed diagnosis.[2]

DIAGNOSIS

It is well known that, in some cases, the diagnosis of meningitis in the young infant may be extremely difficult, mainly because of the absence of the characteristic signs: the bulging anterior fontanel; nuchal rigidity; projectile vomiting; and positive Brudzinski's and Kernig's signs.[3] Cyanosis, fever, vomiting, or, perhaps, icterus, which in themselves are not symptomatic of meningitis, may nevertheless be present and misleading. An unexplained sepsis makes a cerebrospinal fluid study imperative, for that alone may disclose meningitis. The physician should be alert to the least suggestion of meningitis in obscure conditions, for earliest possible recognition of meningitis and isolation of the causative organism are essential to recovery. In some cases, direct smears can be made and the organism identified; otherwise cultures are required to reveal the causative organism. Escherichia coli meningitis is the most frequent form found in the infant.[3]

REPORT OF A CASE

A full-term infant, weighing 10 lb. 8 oz. (4,762.7 gm.) was born on April 7, 1953, with the aid of outlet forceps. On physical examination a few hours later, the infant was apparently normal. The mother had been in good health throughout pregnancy. The day after birth, however, a right cephalhematoma over the parietal area was observed. The temperature peak that day was 101 F (38.3 C) but dropped to normal at the end of the day. The infant had begun to feed and was taking the offerings well. On the fifth day the temperature was elevated to 103.2 F (39.6 C). The infant did not appear acutely ill but had a fulness of the anterior fontanel and a bilateral internal squint. The cephalhematoma was still present. Because of the physical findings, a tentative diagnosis of meningitis was made. A spinal tap revealed 1,450 cells per cubic millimeter; 90% lymphocytes; Pandy's test for globulin, +3; protein, 105 mg. per 100 cc.; sugar, 26 mg. per 100 cc.; and chlorides, 732 mg. per 100 cc. A direct smear of the centrifuged cerebrospinal fluid specimen revealed an occasional gram-negative bacillus. Culture of the spinal fluid and bacterial sensitivity reactions to the various antibiotics were ordered, but through an error no blood cultures were done. Procaine penicillin was given intramuscularly, 150,000 units twice daily; and chlortetracycline, 25 mg. per kilogram of body weight every 24 hours, was given orally. Medication was arbitrarily chosen. Within the next 24-hour period, the general condition of the infant was improved. The anterior fontanel was less tense; the temperature began to drop until it was normal within 48 hours after the onset of therapy.

Three days after the spinal tap had been done, the laboratory reported a positive Esch. coli growth. The sensitivity tests showed maximal reaction for chloramphenicol and streptomycin and only moderate reaction for oxytetracycline and chlortetracycline. With the offending organism identified, therapy was modified. Penicillin therapy was discontinued, and the dosage of chlortetracycline raised to approximately 35 mg. per kilogram of body weight every 24 hours. The infant tolerated this dosage well. A spinal tap done six days after the original one revealed 263 cells per cubic millimeter. The cultures were negative for growth. The infant was discharged from the hospital at 20 days of age, 15 days after the onset of illness. Medication continued at home consisted of chlortetracycline, given in doses of 25 mg. per kilogram of body weight every 24 hours. There still remained an internal squint in one eye, and the size of the cephalhematoma remained unchanged. Repeated blood cell counts as well as urinalyses were within normal range. Roentgenographic examination revealed no evidence of abnormalities in the osseous components. An 8 by 5 cm. diameter soft tissue density was present in the right parietal area representing a rather large cephalhematoma.

The infant was seen at home at three-day intervals. Two weeks after discharge from the hospital, he was returned for a spinal tap, which revealed 48 cells per cubic millimeter. The eye squint had disappeared. Two weeks subsequently another spinal tap revealed 16 cells per cubic millimeter. It was thought safe to discontinue medication at this point. The patient had been treated for six weeks. The size of the cephalhematoma, however, had still not changed. At the age of 2 months, when the child was seen at the office, the cephalhematoma was breaking down at its medial aspect as evidenced by a fluctuant erythematous area, 2 cm. in diameter. The child did not appear ill; temperature was not elevated. The impression at that time was of a secondary infection of the cephalhematoma. After treatment with hot wet dressings and with penicillin injected intramuscularly for six days without significant improvement, the cephalhematoma was incised. A thin watery material obtained from the area suggested an Esch. coli infection, which was confirmed by culture study. At this time the sensitivity report read: "sensitive to Chloromycetin, streptomycin and terramycin; moderately sensitive to Aureomycin."

Oxytetracycline therapy, 25 mg. per kilogram of body weight every 24 hours, was instituted and continued for a month. After that period, the head returned to normal size and has remained so during one and one-half years of close observation. The infant appears normal in every respect.

TREATMENT

Occasionally among the wide-spectrum antibiotics, one drug is more specific against an organism than another. It is important that the drug chosen have the widest spectrum of bacterial activity; otherwise decisive time may be lost because of a less active drug. In the case presented, the organism had not been identified; therefore, penicillin and chlortetracycline were chosen in combination. The antagonism of drugs was considered. Inasmuch as it was not known which would be the more efficacious, both drugs were used. Therapy

was readjusted when the identity of the organism became known. Laboratory tests indicated only moderate sensitivity of the organism to chlortetracycline; nevertheless, clinically it appeared that the child was reacting well to the medication, as indicated by lowered temperature and decreasing prominence of the fontanel. For this reason, it was decided to make no changes.

COMMENT

What relationship existed between the meningitis and the cephalhematoma is not clear. The cephalhematoma might have become secondarily infected, although no signs of fracture were seen in the roentgenogram.[4] Kendall and Woloshin [4] have reported that in cephalhematomas there is a 25% incidence of skull fracture in the same area. A similar case has been reported of a cephalhematoma that was sterile on aspiration.[5]

SUMMARY AND CONCLUSIONS

A 5-day-old infant who developed an Escherichia coli meningitis was followed for one and one-half years. Mental and physical development has been normal. Delay in diagnosis of the primary condition is generally the cause of poor results. It is emphatically important to identify the causative organism. Culture studies are therefore necessary. Clinical judgment in therapy, however, takes precedence over laboratory reports.

ABSCESS OF THE EPIGLOTTIS

PROBLEM IN DIFFERENTIAL DIAGNOSIS

Nina C. Ellenbogen Raim, M.D.
Jerome Raim, M.D.
and
Louis Lytton, M.D., Miami, Fla.

The following report concerns the case of a patient with acute epiglottic abscess of Pseudomonas origin. This case report serves to illustrate the difficulty of differentiating epiglottic abscess from an attack of bronchial asthma. Primary abscess of the epiglottis is a rare entity. Epiglottic abscess formation is more frequent in adults than children. In a 10 year period at the Graduate Hospital of the University of Pennsylvania only four cases of epiglottic abscess in adults were observed. They most commonly occurred as a complication of acute pharyngitis associated with abscess of the lingual tonsil.[1] The pathogenic micro-organisms vary. Streptococci are isolated most frequently. In a report of 13 cases of epiglottic suppuration in which cultures were taken, Streptococcus hemolyticus was found in pure culture in 6 cases. Other organisms reported were Hemophilus influenzae, Escherichia coli, Pseudomonas aeruginosa, Micrococcus catarrhalis, Micrococcus (Staphylococcus) aureus, and pneumococci.[2]

REPORT OF A CASE

A 42-year-old man came into the emergency ward of Jackson Memorial Hospital complaining of shortness of breath of two hours' duration. Nine hours prior to admission, the patient ate a hamburger and shortly thereafter became nauseated. In an attempt to induce vomiting, he put his finger down his throat and vomited and immediately had the feeling that "something was stuck in his throat." Shortly afterwards, he experienced pain and dysphagia. Past history of significance revealed asthma since childhood and recurrent attacks of acute tonsillitis. Physical examination revealed a well-developed, extremely muscular white man with a thick, bull neck. When first seen, approximately eight hours after vomiting, he was extremely apprehensive, but no dyspnea was noted. The temperature was 101 F (38.3 C) rectally, respirations 34, and pulse rate 140 per minute. His mucous membranes were observed to be pink, although his face was cyanotic. The nares were clear. The anterior tonsillar pillars and posterior pharynx were deeply erythematous. The palatine tonsils were both enlarged, met in the midline, and were intensely edematous and infected. Inspiratory and expiratory rales were heard throughout both lung fields. No suprasternal, intercostal, or sternal retraction was noted.

The patient was given 200 mg. of phenobarbital (Luminal) intramuscularly, 50 mg. of diphenhydramine (Benadryl) hydrochloride, and 0.5 gm. of aminophylline intravenously. He became steadily worse. Dyspnea was now apparent, and the patient became more apprehensive. He suddenly developed a crowing inspiratory stridor, extreme hoarseness, and marked cyanosis, and then he lost consciousness. A blood pressure reading could not be obtained. A tracheotomy was done immediately. When an airway was established, the patient regained consciousness; however, dyspnea persisted for some period of time. A posterior pharyngeal culture was obtained at this time. With the tracheotomy tube in place, a gloved finger was used to palpate the pharynx. Palpation revealed marked swelling and edema of both tonsils. The right posterior pharyngeal area was indurated. An indirect laryngeal examination could not be done at this time because of marked edema. The day following admission another throat culture was taken. The patient could not swallow, and he was maintained on intravenously administered fluids. Treatment with combined penicillin and dihydrostreptomycin (Combiotic) was started. The first culture obtained grew a pure culture of Pseudomonas. Sensitivity studies were not returned for several days, and because of the dysphagia, nitrofurantoin (Furadantin), 100 mg. dissolved in a glass of water was used as a gargle by the patient three times a day.

The second culture grew Pseudomonas, alpha Streptococcus, and Micrococcus catarrhalis. Pseudomonas sensitivity studies when obtained revealed: chloramphenicol (Chloromycetin), streptomycin, dihydrostreptomycin, and polymyxin, slightly sensitive; chlortetracycline (Aureomycin), oxytetracycline (Terramycin), bacitracin, and penicillin, resistant; nitrofurantoin studies were not obtained. The second day after admission an indirect laryngoscopy examination was performed. The vocal cords appeared normal, but the epiglottis was large, red, and edematous. In the center of the epiglottis, an elevated yellow area was seen. This appeared to be open and draining. Daily indirect mirror examinations of the epiglottis revealed the edema, erythema, and the size of the abscess to be steadily decreasing as was the tonsillar swelling and dysphagia. Seven days after admission the patient's temperature returned to normal and mirror examination revealed that all epiglottic edema and exudate had disappeared. The tracheotomy tube was withdrawn after a well-tolerated trial period of complete blockage.

COMMENT

This case report illustrates an actual problem in differential diagnoses between an acute bronchial asthmatic attack and an acute upper repiratory obstruction. In this case a history of bronchial asthma was present, along with that of frequent attacks of acute tonsillitis. Asthmatic

rales as well as tonsillar and pharyngeal injection were present. Dyspnea was evident, but no retraction could be seen. A diagnosis of an acute asthmatic attack was made, but the more urgent pathology of epiglottic abscess, edema, and upper respiratory obstruction was not noted until later. The causative organism is interesting in its rarity.

SUMMARY

A case of Pseudomonas abscess of the epiglottis was proved by smear and culture. The problem exists of diagnosis between an acute asthmatic attack and upper respiratory obstruction.

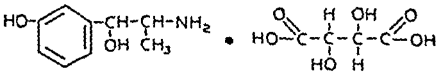
COUNCIL ON PHARMACY AND CHEMISTRY

NEW AND NONOFFICIAL REMEDIES

Monographs and supplemental statements on drugs that appear in this column have been authorized by the Council for publication and inclusion in New and Nonofficial Remedies. They are based upon the evaluation of available scientific data and reports of investigations.

H. D. Kautz, M.D., *Secretary.*

Metaraminol Bitartrate.—$C_9H_{13}NO_2.C_4H_6O_6$.—M.W. 317.29.—*l*-*α*-(1-Aminoethyl)-*m*-hydroxybenzyl alcohol hydrogen *d*-tartrate.—*l*-1-(*m*-Hydroxyphenyl)-2-amino-1-propanol hydrogen *d*-tartrate.—The structural formula of metaraminol bitartrate may be represented as follows:

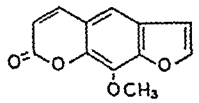


Actions and Uses.—Metaraminol bitartrate, a sympathomimetic amine compound, has vasoconstrictor properties similar to those of ephedrine, but it is more potent and it exhibits less of the central stimulant effects of that drug. It also exhibits both the action of the aromatic hydroxy-substituted compounds and the prolonged effect of the isopropylamines. Metaraminol bitartrate is used topically as a nasal decongestant in the symptomatic relief of nasal edema accompanying the common cold, rhinitis, sinusitis, and nasopharyngitis. It provides relatively prolonged shrinkage of the nasal mucous membranes with virtually no stinging, irritation, or secondary engorgement. Depression of ciliary activity is minimal. Clinical use has revealed no evidence of undue central stimulation. Undesirable side-effects such as tremor, palpitation, tachycardia, and insomnia seldom occur when the drug is administered as indicated; however, because of its vasoconstricting action, care must be taken not to exceed the stated dosage.

Dosage.—Metaraminol bitartrate is administered topically as an isotonic solution containing 0.25% of the base, buffered to a pH of 6, which is within the range of normal nasal secretion. It may be applied with a dropper or an atomizer. The solution should be at room temperature or slightly above for application. The usual dose is 2 or 3 drops or one or two sprays in each nostril, which may be given every 3 hours but not more than four times daily. Treatment may be continued for a period not to exceed one week. The 0.25% solution also may be applied to tampons for intranasal application.

Sharp & Dohme, Division of Merck & Co., Inc., cooperated by furnishing scientific data to aid in the evaluation of metaraminol bitartrate.

Methoxsalen.—$C_{12}H_8O_4$.—M.W. 216.20.—δ-lactone of 3-(6-hydroxy-7-methoxybenzofuranyl)acrylic acid.—8-Methoxypsoralen.—Xanthotoxin.—The structural formula of methoxsalen may be represented as follows:



Actions and Uses.—Methoxsalen, a methoxypsoralen derivative, increases the production of melanin pigment in the skin when exposed to ultraviolet light. Oral administration of the drug decreases, whereas topical use increases, the erythemic response of the skin to ultraviolet rays, possibly because local application produces a higher skin concentration. Methoxsalen is useful for the treatment of idiopathic vitiligo when used in conjunction with exposure of affected areas of the skin to ultraviolet light. Sunlight having an effective ultraviolet component is preferable as a source of such radiation, but a suitable artificial source can be employed effectively. Methoxsalen therapy is not of value in patients who cannot be exposed to ultraviolet light. Methoxsalen has no effect on leukoderma associated with the destruction of melanocytes, which occurs following severe burns and trauma; also it is not known to influence leukoderma consequent to infections such as pinta or leprosy.

Methoxsalen is extremely potent and should be employed only under medical supervision to avoid overdosage and potential toxic effects. Serious burning of the skin can result from incorrect topical use. Whenever blistering occurs, topical application and exposure to sun or ultraviolet lamp should be discontinued. Oral medication may be maintained unless edema occurs at time of blistering. Oral use then should be discontinued until edema is corrected. If acute dermatitis develops, it should be treated before resuming topical therapy. Oral therapy may be unwise in patients with only a few isolated areas of depigmentation, because of the increased danger of systemic toxic effects. Oral administration occasionally is associated with unpleasant side-effects such as gastric irritation, nausea, nervousness, insomnia, and depression. If these occur, oral dosage should be reduced. Since the drug is potentially hepatotoxic, it is contraindicated in the presence of hepatic insufficiency or diabetes mellitus. Liver function tests should be performed monthly on all patients for the first three months and at less frequent intervals throughout the course of therapy. Physicians should weigh the relative importance of possible psychological benefits against potential harmful effects in the employment of methoxsalen therapy for a benign cosmetic disease such as vitiligo.

Dosage.—Methoxsalen is administered orally and/or topically and only in conjunction with appropriate exposure of the affected skin to ultraviolet rays. Since topical application can be applied to only a few lesions at a time, oral therapy is more suitable for patients with extensive areas of depigmentation. Oral therapy also may be employed in conjunction with topical application, provided the locally treated areas, which thus are rendered more susceptible to ultraviolet rays, are protected from overexposure. Examination of the skin under Wood's light before and during treatment will aid in estimating varying degrees of depigmentation and repigmentation as a guide to therapy.

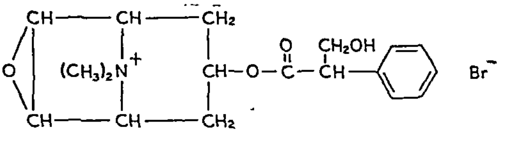
The suggested oral dosage for adults is 20 mg. once daily, administered approximately 2 hours prior to ultraviolet exposure. For children 1 to 6 years of age, an oral dosage of 10 mg. once daily, similarly timed, is suggested; for those 6 to 12 years of age, a dosage of 10 to 20 mg. once daily is suggested. Oral medication may be followed by a drink of milk and/or the use of a sedative to minimize side-effects. When oral therapy is employed alone, the vitiliginous skin is exposed to sunlight or a suitable artificial source of ultraviolet light for 5 minutes daily. This should be increased slowly until the affected areas are being exposed for at least 30 minutes after each oral dose.

Topical therapy is applied in the form of a 1% lotion. It should be applied only once weekly and to only a few of the depigmented areas, followed by exposure of the treated areas to ultraviolet light for a period not to exceed one minute. When an artificial source of ultraviolet light is employed, the initial exposure should be made with one-half the minimal erythemic dose. It is desirable to alternate the sites of weekly topical applications in order to prevent severe erythema and to promote uniform repigmentation.

When oral medication is to be employed concomitantly with topical therapy, it is absolutely essential to protect the topically treated areas from daily exposure to ultraviolet light, or severe burning will result. In conjunction with the stated oral dosage and topical concentration, the locally untreated and topically treated areas should be exposed to ultraviolet rays only as indicated previously. Although repigmentation may begin to show in some patients within a few weeks, other patients may require therapy for as long as 6 months before improvement is observed.

Paul B. Elder Company cooperated by furnishing scientific data to aid in the evaluation of methoxsalen.

Methscopolamine Bromide.—$C_{18}H_{24}BrNO_4$.—M.W. 398.30.—Epoxytropine tropate methylbromide.—The structural formula of methscopolamine bromide may be represented as follows:



Actions and Uses.—Methscopolamine bromide, a parasympatholytic agent, produces the antisecretory and antispasmodic actions characteristic of anticholinergic drugs. It has greater selectivity than atropine in blocking vagal nerve impulses concerned with gastric secretion, and it is capable of suppressing both the volume and the acidity of gastric secretion. Methscopolamine bromide also delays gastric emptying and reduces peristaltic activity of the intestinal tract. The drug also inhibits salivary secretion and sweating.

Methscopolamine bromide is useful as an adjunct in the management of peptic ulcer, certain forms of gastritis associated with hyperacidity and hypermotility, hypermotile dysfunction of the intestinal tract such as functional diarrhea (irritable bowel, mucous colitis, spastic colon) and diarrhea associated with extensive bowel resections and ileostomies, hyperhydrosis or sweating that aggravates certain dermatoses, and excessive salivation. Its effectiveness in biliary dyskinesia or for ureteral and vesical spasm has not been established.

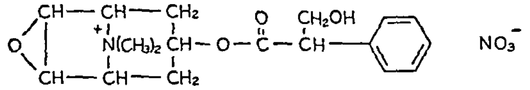
In doses exceeding those usually required to produce its peripheral atropine-like effects, methscopolamine may induce a ganglionic blocking action similar to that of tetraethylammonium chloride. Its ganglionic blockade potency is about 60% that of tetraethylammonium, and doses of methscopolamine sufficient to induce such action may produce serious side-effects. With still higher doses, the drug produces a toxic curare-like blocking action at the myoneural junction.

The most commonly reported side-effects are dryness of the mouth, constipation, and blurring of vision caused by the cycloplegic and mydriatic actions of the drug. Because of the latter, the drug is contraindicated in patients with glaucoma. Less commonly observed side-effects are difficult urination, dysphagia, heartburn, dizziness, palpitation, flushing or excessive dryness of the skin, drowsiness, headache, and nausea. The occurrence or degree of some of these side-effects frequently diminishes with continued administration of the drug or after temporary withdrawal and reduction in dosage. Chewing gum may mitigate mouth dryness. Patients who experience blurred vision should be warned against operating vehicles or other machinery. Constipation, caused by reduction in intestinal motility, also may be troublesome. Because of the action of the drug in delaying gastric emptying, it should be used cautiously, if at all, in pyloric obstruction. Caution likewise is necessary in prostatic hypertrophy, in patients with a history of urinary retention caused by other anticholinergic drugs, and in patients generally intolerant to anticholinergic therapy or in whom the desired actions are not obtained before the dosage approaches toxic levels.

Dosage.—Methscopolamine bromide is administered orally. The usual daily oral dosage for adults is 2.5 to 5 mg. administered one-half hour before meals and at bedtime. The bedtime dose may be as high as 10 mg. Dosage must be individualized, and, unless the symptoms associated with the condition under treatment are unusually severe, it is advisable to begin therapy with the minimum doses. This is essential in patients with a history of intolerance to anticholinergic drugs. In peptic ulcer, control of symptoms with small doses usually can be achieved in conjunction with appropriate use of antacids and management of the diet. When symptoms are severe, the higher dose level may be administered initially, but it should be reduced if unpleasant side-effects develop. When the minimum doses are ineffective initially, they may be increased gradually to tolerance until the desired response occurs. If severe side-effects appear, therapy should be temporarily discontinued and then resumed at a lower dose level. When side-effects overshadow the desired action, the drug should be completely withdrawn.

The Upjohn Company cooperated by furnishing scientific data to aid in the evaluation of methscopolamine bromide.

Methscopolamine Nitrate.—$C_{18}H_{24}N_2O_7$.—M.W. 380.41.—Epoxytropine tropate methylnitrate.—The structural formula of methscopolamine nitrate may be represented as follows:



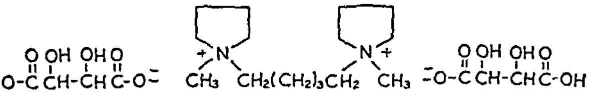
Actions and Uses.—Methscopolamine nitrate is a parasympatholytic agent that has the same actions, uses, and contraindications as methscopolamine bromide. See the monograph on methscopolamine bromide.

Dosage.—Methscopolamine nitrate is administered orally or parenterally by either subcutaneous or intramuscular injection. Injection of the drug should be reserved for patients requiring unusually prompt action or in whom oral medication is not feasible. The dosage of methscopolamine nitrate is approximately equal to that for methscopolamine bromide since, on the basis of their molecular weights, the same amount of the nitrate salt contains only slightly more of the base.

The usual oral dosage for adults is 2 to 4 mg., administered one-half hour before each meal and upon retiring. The duration of action of a single dose is about 6 hours after absorption into the blood. A 2 mg. dose in enteric coated form to delay action of the drug can be given at bedtime to provide a more prolonged effect. Larger daily or bedtime doses may be required for severe symptoms. The total daily oral dosage should not exceed 12 mg. In peptic ulcer small doses usually are adequate to control symptoms when used in conjunction with appropriate dietary measures and antacids. The usual parenteral dose for adults is 0.25 to 0.5 mg. injected in a suitable solution, either subcutaneously or intramuscularly, three or four times daily until oral medication can be instituted.

R. J. Strasenburgh Company cooperated by furnishing scientific data to aid in the evaluation of methscopolamine nitrate.

Pentolinium Tartrate.—$C_{23}H_{42}N_2O_{12}$.—M.W. 538.61.—Pentamethylene-1,1′-bis-(1-methylpyrrolidinium bitartrate).—The structural formula of pentolinium tartrate may be represented as follows:



Actions and Uses.—Pentolinium tartrate, a quaternary ammonium compound, is a potent ganglionic blocking agent, qualitatively similar in action to tetraethylammonium and hexamethonium compounds. It inhibits the transmission of nerve impulses mediated through both sympathetic and parasympathetic ganglions of the autonomic nervous system. Blocking of sympathetic ganglions, which mediate impulses causing vasospasm, particularly in the lower extremities, produces increased blood flow and hypotension. Similar interference with parasympathetic stimuli may produce loss of ocular accommodation, decrease or cessation of motility of the gastrointestinal tract, and alteration of bladder function. The dose of pentolinium required to produce ganglionic blockade is smaller than that of hexamethonium, and it has a longer duration of action, necessitating less frequent administration. When administered orally, pentolinium tartrate appears to exert less costive effect than does hexamethonium chloride. Tolerance to pentolinium develops with continued use, as with hexamethonium, but a significant degree of cross tolerance has not been observed.

Pentolinium tartrate is useful clinically in the selective management of severe, moderately severe, and malignant stages of hypertension. Ganglionic blockade usually is more effective for controlling severe episodic elevations of blood pressure than for mild labile hypertension. Like other ganglionic blocking agents, the drug may be expected to prove beneficial in the diagnosis and treatment of peripheral vasospastic disorders, but appropriate clinical studies will be required to determine its usefulness, route of administration, and dosage for that purpose.

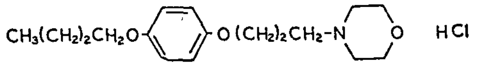
Pentolinium tartrate is associated with the same side-effects as other ganglionic blocking agents. Parasympathetic blockade may produce blurring of vision and dryness of the mouth. Urinary retention or delayed emptying of the bladder may occur, especially in older patients with prostatic enlargement. The hypotensive effect of sympathetic blockade usually predisposes patients to some degree of postural hypertension and syncope. Overdosage may induce peripheral circulatory collapse. Its use is dangerous in patients who have lost blood recently because the drug blocks normal compensatory vasoconstrictor mechanisms. As the drug is more slowly and less completely absorbed orally than parenterally, larger oral doses are required to produce the same effect. Either injection or oral administration may be associated with constipation or diarrhea, depending on the dominance of sympathetic or parasympathetic blockade, but constipation is more commonly encountered, especially when the drug is given orally. The oral costive effect aggravates erratic absorption and may lead to an exaggerated response to the drug unless strict attention is paid to maintaining regular bowel evacuation. The drug is contraindicated in organic pyloric stenosis, recent myocardial infarction, severe coronary insufficiency, and cerebral arteriosclerosis (encephalopathy). Renal disease is not an absolute contraindication, except when impairment of renal function can lead to systemic accumulation of the drug or when lowered blood pressure leads to further renal insufficiency, as in patients with a blood urea nitrogen above 80 mg. per 100 cc. that persists in the presence of lowered blood pressure.

Dosage.—Pentolinium tartrate is administered orally or by intramuscular or subcutaneous injection only. Slow dissociation of the bitartrate ion makes response to the drug unpredictable when given intravenously. Dosage is expressed in terms of the salt. Injection therapy preferably should be instituted in the hospital. In hypertension the dosage of the drug should be aimed at producing a gradual decrease in blood pressure and care must be taken in estimating dosage to distinguish between casual (office) versus basal (home) blood pressure determinations. The initial single parenteral dose should not exceed 3.5 mg., and, in patients known to be susceptible to the drug, 2.5 mg. If this dose does not produce the desired response, increments of 0.5 to 1 mg. then are administered at not less than 4 to 6 hour intervals to avoid cumulative effect. Maximum effect usually occurs 2 hours after each injection. When an effective dose is established, this can be supplemented with smaller doses at 6 to 8 hour intervals until a satisfactory daily regime is achieved for the individual patient. The total effective parenteral daily dosage usually ranges from 30 to 60 mg., divided as indicated previously. Patients should be requested to lie down if giddiness occurs and should not be permitted to rise suddenly after injection.

The initial oral dosage should be 20 mg. every 8 hours for 2 to 7 days in ambulatory patients and for 2 to 3 days in hospitalized patients. Increases in oral dosage of 20 mg. are then made at 2 to 7 day intervals until the minimum effective dosage is reached. The total oral daily dosage may vary from as low as 60 mg. to as high as 600 mg. in exceptionally refractory cases. Termination of hypotensive therapy by either route should not be abrupt unless severe side-effects supervene. Severe postural hypotension may be combated by the administration of vasopressor drugs, pending readjustment in dosage of pentolinium. Physostigmine or pilocarpine may be used to overcome blurring of vision or severe mouth dryness. The drug should be temporarily discontinued if constipation cannot be controlled.

Wyeth Laboratories, Inc., cooperated by furnishing scientific data to aid in the evaluation of pentolinium tartrate.

Pramoxine Hydrochloride. — $C_{17}H_{27}NO_3.HCl$. — M.W. 329.88. — 4-[3-(*p*-Butoxyphenoxy)propyl]morpholine hydrochloride.—The structural formula of pramoxine hydrochloride may be represented as follows:



Actions and Uses.—Pramoxine hydrochloride is a surface anesthetic agent chemically distinct from local anesthetic compounds of the benzoate ester type such as procaine. Its index of sensitization appears to be lower than that of procaine derivatives, and its distinct chemical structure is likely to minimize the danger of cross sensitivity reactions in patients allergic to other local anesthetics. Pramoxine hydrochloride produces satisfactory surface anesthesia and is reasonably well tolerated on the skin and less delicate mucous membranes. It should not be injected because of its tendency to irritate tissues; for the same reason it should not be used in the eye or nose.

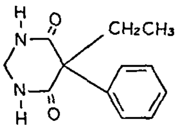
Pramoxine hydrochloride is useful topically for a variety of purposes: to relieve surface pain or itching involving external injuries such as minor burns and wounds, dermatoses, pruritic syndromes, surgical wounds such as episiotomy and hemorrhoidectomy, anal lesions and dilatations, and rectal examinations including sigmoidoscopy; to anesthetize laryngopharyngeal surfaces prior to instrumentation or to obtund laryngospasm during general anesthesia; and to facilitate endotracheal and intragastric intubation (exclusive of bronchoscopic and gastroscopic procedures). In chronic syndromes its prolonged use should be avoided, with efforts directed rather toward correction of the underlying cause.

Pramoxine hydrochloride has a low toxicity and its surface application has not been associated with serious untoward effects. Although its sensitizing potential is low, the possibility of allergic reactions should be borne in mind. Initial burning or stinging prior to the onset of anesthesia is occasionally encountered, but this should not contraindicate its application except in the eye and nose.

Dosage.—Pramoxine hydrochloride is administered topically. It is applied to the affected area in a concentration of 1% as a cream, jelly, or solution. The latter can be applied by means of a spray or gauze pads soaked in the solution. Applications usually are repeated every 3 to 4 hours. From 5 to 7 cc. of a 1% solution is required for spraying the laryngopharyngeal surface. The jelly and cream are used also for lubrication of devices for instrumentation and for digital dilatations or examinations.

Abbott Laboratories cooperated by furnishing scientific data to aid in the evaluation of pramoxine hydrochloride.

Primidone.—$C_{12}H_{14}N_2O_2$.—M.W. 218.25.—5-Ethyldihydro-5-phenyl-4,6(1H,5H)-pyrimidinedione.—5-Phenyl-5-ethylhexahydropyrimidine-4,6-dione.—The structural formula of primidone may be represented as follows:



Actions and Uses.—Primidone, a pyrimidine derivative, is related to phenobarbital but has different chemical and pharmacological properties. Animal experiments indicate that its anticonvulsant activity and toxic effects compare favorably with other similar acting drugs. By most experimental methods of comparison, the anticonvulsant potency and neurotoxicity of primidone are somewhat less than those of phenobarbital. Clinically, primidone is effective in the control of grand mal and psychomotor epilepsy, but further clinical studies are required to determine its usefulness in petit mal, minor motor, or focal types of seizures. As with all anticonvulsants, some patients who are refractory to other agents may respond to primidone and vice versa.

Primidone is readily absorbed after oral administration and uniformly distributed in the body tissues. Approximately 60 to 80% of the ingested dose is excreted in the urine within 24 hours. In therapeutic doses more than 90% of the total urinary excretion consists of approximately equal amounts of unchanged primidone and a metabolite, phenylethylmalondiamide. Although crystalluria attributed to this metabolite has been observed in experimental animals after large doses, subsequent urinary solubility studies in both animals and man indicate that crystalluria in the form of either primidone or its metabolite is unlikely to occur from therapeutic doses, except as an artifact caused by the cooling of urine below body temperature.

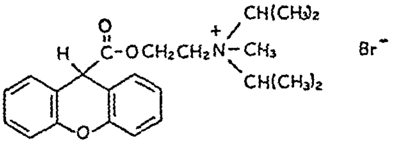
Primidone therapy is associated with undesirable side-effects, but serious toxic reactions have not been reported. No evidence of bone marrow depression or renal damage has been observed. Side-effects include drowsiness, ataxia, psychosis, vertigo, anorexia, irritability, lethargy, general malaise or fatigue, nausea, vomiting, morbilliform skin eruption, painful gums, leg edema, and nonrenal edema of the eyelids. Most side-effects are transitory or mild and may disappear with continuing therapy. When they are persistent or severe, reduction in dosage or complete withdrawal of the drug may be necessary.

Dosage.—Primidone is administered orally. In patients receiving no other anticonvulsant therapy, the usual initial dosage for children over 8 years of age and adults is 0.25 gm. once daily, preferably at bedtime. After 4 to 7 days the dosage may be increased gradually by increments of 0.25 gm. or less at weekly intervals, until the maximum therapeutic effect is attained with minimal undesirable side-effects. When the patient is receiving other anticonvulsant therapy, 0.25 gm. of primidone daily is added to the current medication. This daily dosage is then increased gradually with a concomitant corresponding decrease in the dosage of the agent to be replaced. The transition to primidone should not be completed in less than 2 weeks and, when complete replacement is clinically undesirable, combination therapy may be continued with possible advantage at lower dosage levels for both agents.

In children up to 8 years of age, therapy usually is started with 0.125 gm. of primidone a day, given at bedtime. This is increased by similar weekly increments until the optimal effect is achieved. The same initial dosage is employed for patients in this age group who are receiving another anticonvulsant drug, and, as with adults, gradual increments in primidone dosage should be accompanied by corresponding reductions in the dosage of the drug that is to be partially or completely supplanted. A maximum total daily dosage of 2 gm. should not be exceeded. When the drug is to be discontinued or replaced by other agents, its withdrawal should be gradual unless serious toxic manifestations require immediate cessation of primidone.

Ayerst Laboratories, Inc., cooperated by furnishing scientific data to aid in the evaluation of primidone.

Propantheline Bromide. — $C_{23}H_{30}BrNO_3$. — M.W. 448.42. — β-Diisopropylmethylaminoethyl 9-xanthenecarboxylate bromide. — β-Diisopropylaminoethyl xanthene-9-carboxylate methobromide. — The structural formula of propantheline bromide may be represented as follows:



Actions and Uses.—Propantheline bromide, the isopropyl analogue of methantheline bromide, has the same cholinergic blocking actions, uses, and side-effects. (See New and Nonofficial Remedies under the monograph on methantheline bromide.) Propantheline bromide is somewhat more potent (effective in smaller doses) and exhibits less severe, though not less frequent, side-effects. It should be used with the same precautions as methantheline bromide.

Dosage.—Propantheline bromide is administered orally or parenterally by either intramuscular or intravenous injection. Parenteral administration should be reserved for patients unable to take the drug orally. The average oral dosage for adults is 15 mg. three times daily with meals and 30 mg. at bedtime. For control of patients with peptic ulcer, more than the 15 mg. unit dosage is frequently required and some patients may require up to 60 mg. four times daily or an additional dose about the middle of the night. The average parenteral dosage for adults is 30 mg. every 6 hours intramuscularly or intravenously. For intravenous administration, a dose of 30 mg. should be dissolved in not less than 10 cc. of water for injection. Dosage always should be adjusted to the minimum required to control parasympathomimetic symptoms and should be in accordance with suitable dietary measures and other medication that may be indicated.

G. D. Searle & Co. cooperated by furnishing scientific data to aid in the evaluation of propantheline bromide.

Radio-Gold (Au^{198}) Colloid.—Radio-gold colloid is a radioactive isotope of gold. The radiations emitted by the isotope are negative beta particles and gamma radiations. The half-life of the isotope is 2.7 days.

Actions and Uses.—Radio-gold (Au^{198}) colloid is a colloidal concentrate of radio-gold (Au^{198}) from which suitably dilute solutions are prepared for parenteral injection. The radio-gold particles in the colloid range from 0.003 to 0.007 μ in diameter. The isotope, radio-gold (Au^{198}), is prepared from stable gold (Au^{197}) by neutron bombardment in a nuclear reactor. It has a half-life of 2.7 days and its radiation consists essentially of 0.97-Mev beta and 0.411-Mev gamma rays. Its mean effective life is 3.9 days, and about 95% of the radiation is delivered in 11 days. The colloid is quite stable to heat, but it should not be autoclaved under pressure. It may be mixed with saline or local anesthetic solutions, radiopaque mediums, pectin, and other agents, but it is readily flocculated by metallic ions such as aluminum.

Radio-gold (Au^{198}) colloid, given by intracavitary injection, is useful in dilute solutions for the irradiation of closed serous cavities in the palliative treatment of ascites and pleural effusion associated with metastatic malignancies. Dilute solutions also may be employed as a palliative prophylactic against the dissemination of tumor cells after surgical exposure and/or removal of tumors from these serous cavities, provided healing of the surgical wound by primary intention has begun. In the peritoneal or pleural cavities the radio-gold particles are absorbed on the walls in aggregates, which are then phagocytosed; some may be dispersed by transport via the lymphatics. The exact mechanism of intracavitary action is unknown. Although there is no evidence that it prolongs life, it contributes to the comfort of cancer patients by reducing fluid accumulation. Intracavitary administration should not be employed when the cavities are not definitely closed because of the hazard of radiological contamination by leakage, nor should it be employed when the presence of large tumor masses may indicate the need for other more effective methods of treatment. In the prophylactic intracavitary irradiation of disseminated tumor cells, the possibility of delayed healing or breakdown and leakage of subsequent surgical wounds should be kept in mind if further operative exposure becomes necessary during the effective life of the radioisotope. Intracavitary palliative irradiation with radio-gold should not be undertaken prior to establishing a diagnosis of malignant metastatic involvement.

Radio-gold (Au^{198}) colloid is not recommended for interstitial infiltration of malignant tumors such as discrete prostatic or female pelvic carcinomas and other tumor masses. Conclusive evidence is not available to indicate that its usefulness for this purpose, in comparison with other forms of treatment, is not outweighed by the hazard of radiological contamination caused by leakage from the site of deposition. Leakage may result from surgical exposure or ulcerating lesions that communicate with the exterior. The use of closed techniques for interstitial infiltration may reduce the hazard of leakage from accessible nonulcerating tumors, but this problem requires further study.

Radio-gold (Au^{198}) colloid should not be employed intravenously in the treatment of leukemia, because it is ineffective against acute leukemias and is inferior to the majority of other agents used in chronic leukemias.

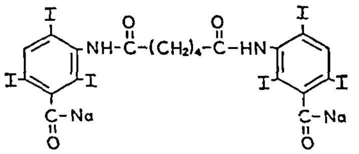
Intracavitary use may be followed by mild radiation sickness after 3 or 4 days and by decrease in the white blood cell count, which usually returns to normal within a few days after injection. Hypoplasia of the bone marrow has occurred in terminal cases treated with radio-gold colloid. Pronounced fibrosis also has been noted occasionally. Since patients become a source of radiation after treatment, appropriate evaluation of this is essential to avoid dangerous exposure of nursing and other personnel involved in their care.

It should be borne in mind in the handling of this radioisotope that the possible untoward effects of its predominant beta ray component (90 to 94%) are not completely understood and that in the use of large doses there is need for further caution to avoid excessive radiation of surrounding normal tissues by the smaller gamma ray component (6 to 10%).

Dosage.—Radio-gold (Au^{198}) colloid is administered by intracavitary injection in doses ranging from 35 to 150 mc. (millicuries). All fluid is removed from the affected cavity prior to injection, which can be made with equipment ordinarily employed for thoracentesis or paracentesis. In pleural effusion, the usual dose ranges from 35 to 75 mc. per cavity; in the larger peritoneal cavity, the dose usually ranges from 100 to 125 mc. To insure adequate distribution in the cavity, each dose should be diluted with isotonic sodium chloride solution to a volume of 250 to 500 cc., and the patient should be urged to move about occasionally after administration. If desired the colloid concentrate may be injected prior to dilution followed by instillation of the diluent. Doses should not be repeated at intervals of less than 4 weeks and then only as reaccumulation of fluid may require it. The colloid is available for shipment as a solution having an activity of 20 to 40 mc. per cubic centimeter.

Abbott Laboratories cooperated by furnishing scientific data to aid in the evaluation of radio-gold (Au^{198}) colloid.

Sodium Iodipamide.—$C_{20}H_{12}I_6N_2Na_2O_6$.—M.W. 1183.83.—Sodium N,N'-adipyl-bis(3-amino-2,4,6-triiodobenzoate).—Sodium iodipamide is prepared by dissolving the free acid in dilute sodium hydroxide and buffering the solution to pH 6.5-7.7. The salt is not isolated from the solution. The structural formula of sodium iodipamide may be represented as follows:



Actions and Uses.—Sodium iodipamide, a radiopaque water-soluble organic iodine compound, is useful as a roentgenographic contrast medium for intravenous cholangiography and cholecystography to visualize the biliary ducts and gallbladder when these structures or their contents cannot be adequately demonstrated by oral or intraductal contrast mediums. It is not recommended for routine gallbladder series, but for the specific indications noted subsequently. Intravenous cholangiography may be particularly useful for nonsurgical visualization of the biliary ducts, especially in patients with postcholecystectomy syndrome, and for cholecystography prior to surgery when the gallbladder has lost its power to concentrate bile. Intravenous administration may permit visualization of biliary structures in patients who are unable to ingest or absorb oral mediums and who cannot be depended upon to take the prescribed dose. Intravenous cholecystography also may be indicated when rapid visualization is essential for differential diagnosis in emergencies and prior to surgery. It is likewise suitable for cholecystography in infants and small children.

After intravenous administration, sodium iodipamide is promptly and rapidly excreted by the liver, the first traces appearing in the bile within several minutes. Within 15 to 20 minutes, a sufficient amount usually has accumulated to produce radiopacity of the hepatic and common bile ducts. Relatively high concentrations are found within 20 to 25 minutes. Concentrations in the bile may reach 30 to 100 times those in the blood. About one hour after injection, it begins to enter the gallbladder; generally the highest concentration is reached in 2 to 2½ hours. About 90% is finally eliminated in the feces, without absorption into the enterohepatic circulation. Unless liver function is impaired, about 10% or less generally is excreted by the kidneys. In the presence of liver damage, it is excreted by the kidneys in about the same time as that required by the normal liver.

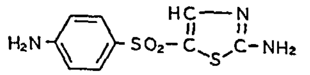
Sodium iodipamide given intravenously usually is well tolerated when administered slowly. Transient restlessness, sensations of warmth, pressure in the upper abdomen, nausea, and vomiting may occur, especially after too rapid administration. Severe reactions have been observed only rarely. It should not be administered to individuals hypersensitive to iodine. It is also contraindicated in patients with hyperthyroidism or with severe impairment of renal function. It should be used with caution in the presence of jaundice or impairment of liver function, especially when the latter is severe or associated with renal dysfunction.

Dosage.—Sodium iodipamide is administered as a 20% solution by slow intravenous injection into the antecubital vein for either cholangiography or cholecystography. An average of 10 minutes should be taken to complete injection of the usual dose. A preliminary test for sensitivity by either intradermal injection of 0.1 cc. or conjunctival instillation of two drops should be made prior to intravenous administration. Appearance of an intradermal wheal or an inflammatory reaction of the conjunctiva within 10 to 15 minutes indicates hypersensitivity.

The usual intravenous dose for adults is 40 cc. of a 20% solution (8 gm.). In thin asthenic patients, 20 cc. (4 gm.) may be adequate. For visualization of the biliary ducts, after usual preliminary preparation for cholecystographic procedures and a "scout film," the patient should be placed in a supine position with the left side elevated about 15 to 30 degrees. Serial roentgen ray exposures at 10 minute intervals should be started 20 minutes after intravenous injection and continued until optimal visualization is obtained. For examination of the gallbladder, exposures are made in the standard positions beginning about 1½ to 2 hours after injection. Additional exposures are made after ingestion of a fat meal. For infants and young children, an intravenous dosage of 0.6 to 1.2 cc. of a 20% solution (0.12 to 0.24 gm.) per kilogram of body weight may be used for cholecystography. A solution of the drug may be stored at room temperature but should be protected from strong light. Solutions kept in the syringe for prolonged periods of time prior to injection also should be protected from strong light.

E. R. Squibb & Sons, Division of Olin Mathieson Chemical Corporation, cooperated by furnishing scientific data to aid in the evaluation of sodium iodipamide.

Thiazolsulfone.—$C_9H_9N_3O_2S_2$.—M.W. 255.31.—2-Amino-5-sulfanilylthiazole.—The structural formula of thiazolsulfone may be represented as follows:



Actions and Uses.—The actions of thiazolsulfone are similar to those of glucosulfone sodium; however, it is less toxic and may be administered orally. The urine of patients receiving the drug may become pink to cherry red in color, caused by the formation of an unidentified dye as a degradation product. The indications for use are the same as those for glucosulfone sodium, but thiazolsulfone seems to be of less value than other sulfones in the treatment of leprosy. The drug may be used in conjunction with streptomycin in the treatment of tuberculosis.

Although thiazolsulfone appears to be relatively free from toxic effects, vomiting, slight cyanosis, methemoglobin formation, and leukopenia occur occasionally. Thyroid enlargement occurs after 2 to 5 months of treatment, and in young persons, prolonged treatment may cause the development of secondary sex characteristics without true sexual maturation.

Dosage.—For adults the initial daily dose should not exceed 4 to 6 gm. given in divided doses. This dose may be increased after the first week by increments of 1 gm. daily until the level of tolerance is reached. For children, the initial daily dose should be 1 gm. given in two divided doses and increased slowly until a blood level of 2 to 3 mg. per 100 cc. is maintained, or until a total daily dose of 5 gm. is reached. After 6 months of treatment, dosage should be reduced to a maintenance level of 1 gm. daily. Any evidence of intolerance or intoxication is an indication for reduction in dosage or cessation of therapy.

Parke, Davis & Co. cooperated by furnishing scientific data to aid in the evaluation of thiazolsulfone.

Crystalline Trypsin.—Crystalline trypsin is a purified preparation of the pancreatic enzyme derived from mammalian glands.

Actions and Uses.—Crystalline trypsin exerts its characteristic proteolytic action upon contact with clotted blood, exudate, and necrotic tissue within a pH range of 5 to 8, optimal at about pH 7. It is inactive on and not harmful to viable tissue because of the presence in serum of a specific trypsin inhibitor and nonspecific inhibitory substances. Such inhibition likewise limits the duration of its proteolytic effect on coagulated blood and exudate.

Crystalline trypsin is useful as an adjunct to surgical management for débridement of necrotic wounds and ulcers, abscesses, empyemas, sinuses, and fistulas. It is also useful to separate eschar from second degree burns and to liquefy hematomas, including intrapleural blood clots in hemothorax. It is not nearly as effective for removal of necrotic tissue as for liquefaction of coagulated blood and exudate. It is chiefly effective in cavities and infected joint spaces where the anatomic configuration permits adequate incubation before extravasation of serum and inactivation of the enzyme can occur. Its action in such cavities also is limited to hematomas and exudate that have not become organized by fibrous tissue. Special caution is necessary in tuberculous empyema because of the possibility that digestion of coagulated exudate may lay bare diseased areas of the visceral pleura and favor the development of a bronchopleural fistula. It should be employed with similar caution in preexisting bronchopleural fistula caused by tuberculosis.

The toxic effects of crystalline trypsin are negligible when the drug is applied topically by local infiltration or irrigation and by intrapleural instillation. When administered by hypodermic infiltration or by instillation into closed cavities or spaces, it produces a histamine-like effect consisting of a mild elevation of temperature and an increase in pulse rate. This reaction may be prevented by preliminary administration of an antihistaminic drug. The enzyme should not be injected into areas of acute inflammation or into normal tissue. On surface lesions, the dry form of the enzyme may produce a severe burning sensation occasionally, especially when the blood supply is poor. A topical anesthetic may be used prior to surface application or antihistaminic medication can be used to alleviate local stinging and pain.

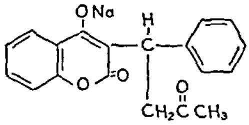
Crystalline trypsin is contraindicated in severe hepatic insufficiency such as acute yellow atrophy or advanced cirrhosis of the liver. Application to actively bleeding cavities also is definitely contraindicated. Likewise it should not be used for débridement of ulcerated carcinomas because of the danger of extending the malignancy. Sensitization or antigenic reactions have not been observed, but this possibility should be kept in mind. The inhalation of an aerosol to liquefy and stimulate expectoration of excessive bronchial secretions is not advised because the questionable clinical benefit of this procedure is outweighed by irritant side-effects. Topical preparations never should be administered intravenously.

Dosage.—Crystalline trypsin is applied to surface lesions either in dry form by means of a powder blower or in a freshly prepared suitable buffer solution by means of wet dressings. For less accessible lesions, such as abscesses, sinuses, and fistulas, the solution may be infiltrated, instilled, or used as an irrigant with a syringe and needle or small catheter; the dry form placed in small gelatin capsules also can be implanted in sinus or fistulous tracts that are difficult to irrigate. For intrapleural administration, the technique of thoracentesis is used; aspiration and irrigation to remove retained fluid should precede instillation of the enzyme. Aspiration 2 hours after each instillation into cavities is advisable to avoid untoward effects.

Crystalline trypsin is assayed for potency on the basis of its decomposition of hemoglobin and the comparative reaction of substances so liberated with that of tyrosine against a standard reagent. The activity is expressed in units or milligrams; 1,000 units is equivalent to 1 mg. of tyrosine or to 1 mg. of lyophilized crystalline trypsin. Crystalline trypsin is stable indefinitely in dry form at room temperature, but, when placed in a suitable buffer solution, 75% of its activity is dissipated within 3 hours. Thus only fresh solutions should be used for wet dressings or for instillation, infiltration, and irrigation. With either dry or wet applications of the enzyme, it is desirable to determine the pH of accessible lesions prior to instituting therapy; this can be determined with the use of nitrazine paper. When the pH is outside the range of 5 to 8 or the lesions are incrusted or dry, the area to be treated should be irrigated or brought into continuous contact for several minutes with Sorensen's phosphate buffer solution before application of the dry powder. For such lesions, wet dressings are prepared by using a fresh solution of 250 mg. (equivalent to 250,000 units) of the crystalline enzyme in 25 cc. of Sorensen's buffer solution as a diluent. That amount usually is adequate also for intrapleural instillation; however, dosage is dependent upon the size, character, and location of the lesion to be treated. Wet dressings and irrigations should be repeated every 3 hours. When the dry powder is used on surface lesions, a thick coating should be applied and maintained. For small areas the powder may be reapplied every 15 to 30 minutes; for large areas reapplication should be made at least every 3 hours. For capsule implantation in sinus or fistulous tracts, the dose is limited by the number and size of capsules that can be inserted. When infiltration or instillation of the solution is employed, this may be repeated once or twice daily as indicated by the condition of the lesion under treatment.

The Armour Laboratories cooperated by furnishing scientific data to aid in the evaluation of crystalline trypsin.

Warfarin Sodium.—$C_{19}H_{15}NaO_4$.—M.W. 330.32.—3-(α-Acetomylbenzyl)-4-hydroxycoumarin sodium.—The structural formula of warfarin sodium may be represented as follows:



Actions and Uses.—Warfarin sodium is a coumarin derivative that produces the blood anticoagulant activity characteristic of similarly acting compounds. It reduces the prothrombin concentration and prolongs the clotting time of the blood, presumably by an action on the liver that reduces prothrombin production. Thus it is useful for the prevention and treatment of diseases resulting from or complicated by intravascular clotting. (See the monographs on bishydroxycoumarin and heparin sodium in New and Nonofficial Remedies.)

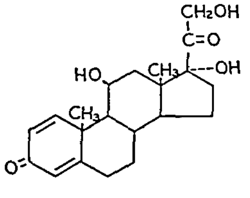
Like other systemic anticoagulants, warfarin sodium does not affect thrombi or emboli already formed, but it retards further intravascular clotting. It may prevent propagation of such clots and permit their dissolution by blood enzymes. Unlike other similar compounds, warfarin sodium can be administered intravenously as well as orally. Intravenously, it acts less rapidly than heparin sodium but more rapidly than older, orally administered coumarin derivatives. It is readily absorbed into the blood after oral administration and also may be employed by this route as an adjunct to initial parenteral therapy. Warfarin sodium is effective in small doses by either parenteral or oral administration, and its duration of action is longer or at least as long as previously available coumarin derivatives. As with other anticoagulant drugs, overdosage may result in hemorrhagic complications; hence frequent determinations of blood prothrombin determinations should be carried out. Salicylates are potentially capable of enhancing the hemorrhagic effect of the drug. In the event of overdosage, therapy should be temporarily discontinued and vitamin K_1 should be employed along with blood transfusion to combat hemorrhage. The drug should not be administered in the presence of visceral bleeding, a preexisting hemorrhagic diathesis, subacute bacterial endocarditis, or impaired hepatic or renal function. Also, it should not be administered to patients recovering from operations on the brain or spinal cord or who are undergoing continuous tube drainage of the stomach, intestine, or urinary tract in the presence of ulceration. It may be used with caution in patients similarly undergoing continuous tube drainage in the absence of ulceration.

Dosage.—Warfarin sodium is administered intravenously or orally. The blood prothrombin time should be determined prior to and after the initial dose, and thereafter at intervals of 24 to 48 hours during the first 2 weeks and not more than 3 days apart for the second 2 weeks. For longer therapy, prothrombin determinations may be made at weekly intervals.

Intravenously, an initial single dose, calculated on the basis of 1 mg. per kilogram of body weight (but not less than 60 mg. nor more than 75 mg.), may be expected to prolong a normal prothrombin time in the therapeutic range of 25 to 45 seconds (whole plasma) within 12 to 18 hours for a period of 5 to 6 days. Subsequent intravenous doses should be approximately two-thirds of the original dose and should be administered after the prothrombin time begins to recede from its peak. Alternatively the second and succeeding doses may be given orally, either 12.5 mg. daily or 25 to 50 mg. every 2 to 4 days. Oral dosage in the latter range usually produces a hypoprothrombinemia lasting about 3 days and should be spaced accordingly. If the oral route is employed initially, a single dose of 75 mg. to 100 mg. produces a therapeutic hypoprothrombinemia lasting 2 to 5 days. Subsequent oral doses should follow the same schedule as when following initial intravenous administration. Patients who are vomiting or have undergone extensive surgery may be more susceptible to the drug, and in such cases the initial intravenous or oral dose should be reduced to 25 or 50 mg. (one-third to two-thirds of the usual initial dose). Because of a latent period of about 12 to 18 hours between administration of the initial intravenous or oral dose and its prolonging effect on blood prothrombin time, it may be advisable to initiate anticoagulant therapy with intravenous heparin sodium in emergency situations. In such cases an appropriate initial dose of heparin sodium may be administered intravenously at the same time or in the same syringe with the proper initial dose of warfarin sodium. The shorter-acting heparin sodium produces a prompt therapeutic effect lasting about 4 hours and can be separately injected again once or twice to cover the latent period before the effect of warfarin sodium is manifest.

Endo Products, Inc., cooperated by furnishing scientific data to aid in the evaluation of warfarin sodium.

Prednisolone. — $C_{21}H_{28}O_5$. — M.W. 360.46. — $\Delta^{1,4}$-pregnadiene-3,20-dione-11,17α,21-triol.—The structural formula of prednisolone may be represented as follows:

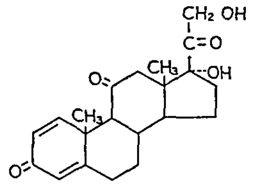


Actions and Uses.—Prednisolone, a dehydrogenated analogue of hydrocortisone, exhibits the same systemic actions and has about the same potency as prednisone. (See monograph on prednisone.) It is less irritant to tissues because of its greater solubility and therefore may be suitable for intra-articular injection.

Dosage.—Prednisolone is administered orally in the same dosage as prednisone. (See monograph on prednisone.) The concentration and dosage for intra-articular injection has not been determined.

Schering Corporation cooperated by furnishing scientific data to aid in the evaluation of prednisolone.

Prednisone. — $C_{21}H_{26}O_5$.—M.W. 342.44.—$\Delta^{1,4}$-pregnadiene-17α,21-diol-3,11,20-trione.—The structural formula of prednisone may be represented as follows:



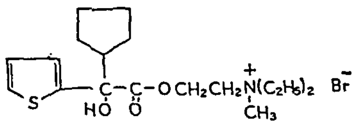
Actions and Uses.—Prednisone, a dehydrogenated analogue of cortisone, shares the actions and uses of the other glucocorticoids employed clinically. It should prove valuable as substitution therapy in frank adrenal insufficiency such as occurs in adrenal cortical hypofunction (Addison's disease) or panhypopituitarism or after adrenalectomy. Prednisone has been shown to control the symptoms of the collagen diseases, including rheumatoid arthritis, disseminated lupus erythematosus, periarteritis nodosa, dermatomyositis, and scleroderma. As with cortisone and hydrocortisone, prednisone generally is effective in the collagen diseases only while therapy is continued. It also has been demonstrated that it has value in the symptomatic management of allergic states, especially intractable bronchial asthma. It is anticipated that prednisone will prove valuable in the symptomatic control of acute rheumatic fever, pemphigus, and the neoplasias of the lymphatic system, as well as other diseases responsive to cortisone and hydrocortisone.

It should be borne in mind that prednisone is an extremely potent compound and that therapeutic dosages will depress the function of the adrenal cortex. It should be used with the same precautions as observed with cortisone and hydrocortisone. Despite the lessened likelihood of sodium retention and potassium excretion, measurement of fluid intake and output and daily weighing of the patient should be performed to give early indication of fluid retention, especially if the diet is without sodium restriction and potassium supplementation. Potassium depletion should always be considered and guarded against. The drug should be withdrawn gradually on cessation of therapy to afford the adrenal an opportunity to recover from the partial atrophy occurring during extended treatment. As with the other glucocorticoids, surgical or medical emergencies in the immediate post-treatment period and before full adrenal recovery may require reinstitution of treatment with prednisone or another glucocorticoid to avoid possible acute adrenal deficiency.

Dosage.—The dose of prednisone, as with the other glucocorticoids, varies with the severity of the disease under treatment and with the individual patient. The drug is administered orally. To control severe conditions a suppressive dosage of 30 to 50 mg. of prednisone daily, divided into four doses, may be required. The suppressive doses may be continued for a period of 2 days to a week then decreased by decrements of 5 or 10 mg. every 4 or 5 days until signs and symptoms recur. The maintenance dose for each patient should be established at the lowest possible daily dosage to maintain comfort and to eliminate signs of the disease being treated. For milder conditions, 5 to 25 mg. daily have proved effective. If it is thought desirable to transfer a patient from cortisone or hydrocortisone therapy to prednisone, an initial dose of 25 to 50% of the steroid originally used should be employed and the dose should be decreased or increased according to the response of the patient.

Schering Corporation cooperated by furnishing scientific data to aid in the evaluation of prednisone.

Penthienate Bromide.—$C_{18}H_{30}BrNO_3S$.—M.W. 420.43.—2-diethylaminoethyl α-cyclopentyl-2-thiopheneglycolate methobromide.—2-diethylaminoethyl 2-cyclopentyl-2-(2-thienyl) hydroxyacetate methobromide.—The structural formula of penthienate bromide may be represented as follows:



Actions and Uses.—Penthienate bromide is an anticholinergic agent that inhibits gastric secretion and motility of the gastrointestinal tract. Its antisecretory effect on both volume and acidity of gastric juice makes the drug suitable for use as an adjunct to dietary measures, antacids, and other medication in the management of peptic ulcer (gastric and duodenal). Penthienate bromide also has been employed in hyperhidrosis, but it appears to be less effective than in gastric hypersecretion. The spasmolytic effect of the drug is more pronounced on the upper than on the lower portion of the gastrointestinal tract; thus penthienate bromide can be expected to inhibit pylorospasm more effectively than spasm of the colon. Its usefulness in gastritis not associated with gastric hyperacidity has not been established. Clinically the drug appears to be helpful in about two-thirds of patients with spastic colon (irritable bowel, mucous colitis, functional diarrhea), but more adequate physiological studies in human beings are needed to determine its ultimate usefulness for this purpose. It has not been found effective in chronic ulcerative colitis.

Penthienate bromide produces atropine-like side-effects in common with other anticholinergic agents that block parasympathetic nerve impulses. At its therapeutically effective dosage level, mouth dryness is common. This rarely is severe enough to necessitate withdrawal and may tend to disappear with continued administration of the drug. Some patients may experience headache, blurring of vision (mydriasis), difficult urination, and constipation or, more rarely, effects on the cardiovascular system such as chest pain, tachycardia, and vertigo. Serious toxic effects have not been encountered. The drug is contraindicated or should be used with caution in glaucoma, urinary bladder neck obstruction, prostatic hypertrophy, cardiac decompensation, coronary insufficiency, achalasia, cardiospasm, and duodenal or pyloric obstruction (until relieved).

Dosage.—Penthienate bromide is administered orally. The usually effective dose for adults ranges from 5 to 10 mg. four times daily. The dose should be individualized, usually at a level sufficient to produce slight mouth dryness. Doses below this level are likely to be ineffective. A dose of 10 mg. four times daily may be required initially in some patients to bring symptoms under control; a total daily dosage of 40 mg. should not be exceeded, and such amounts should not be administered continuously for long periods. Lesser doses usually are adequate for maintenance therapy. In peptic ulcer the drug should supplement other medical management.

Winthrop Laboratories, Inc., cooperated by furnishing scientific data to aid in the evaluation of penthienate bromide.

COMMITTEE ON COSMETICS

Report to the Committee

The following report has been prepared at the request of the Committee.

VERONICA LUCEY CONLEY, *Secretary.*

TREATMENT OF ACNE SCARS BY DERMABRASION

ROTARY BRUSH METHOD

Herbert Rattner, M.D., Chicago
and
Charles R. Rein, M.D., New York

A subject that has aroused a great deal of discussion in dermatological circles concerns the dermabrasion treatment for acne scars. In 1952 Kurtin[1] presented this method of refrigeration-abrasion, which he termed skin planing. Seldom has a new treatment method engendered so much interest. Some resolutely refused to endorse the therapy, and others were enthusiastic about it to an unwarranted degree. The method has since been tried and accepted by many dermatologists throughout the country. Modifications have been introduced and experiences recorded, and now a large enough number of cases have been observed for a long enough period so that a status report of the method seems timely.

The information that seems to interest physicians most involves not only the technical details but such aspects as the types of scars that respond best to the therapy, length and character of convalescence, discomfort involved, complications, frequency of treatments, and probable results.

Professor and Chairman, Department of Dermatology, Northwestern University Medical School, and Editor, *A. M. A. Archives of Dermatology* (Dr. Rattner) and Associate Professor of Clinical Dermatology and Syphilology, New York University Post-Graduate Medical School (Dr. Rein).

[1] Kurtin, A.: Corrective Surgical Planing of Skin, A. M. A. Arch. Dermat. & Syph. 68:389 (Oct.) 1953.

HISTORICAL

The so-called dermabrasion or planing operation is new in technique only, not in principle. In the past, numerous measures were devised to eradicate acne scars, but all of them were found wanting. The various methods consisted of scarification, electrodesiccation, surgical excision, surgical shaving, chemical caustics, cryotherapy (usually by means of a slush made of carbon dioxide or dry ice and acetone), and mechanical abrasion with sandpaper. The last named has been the most widely publicized method in recent years.

The planing method, while employing the same basic principle of abrasion as the sandpaper treatment, has additional innovations that improve immeasurably both the technique and the clinical results. It employs a refrigeration-type anesthesia that both facilitates abrasion and controls bleeding. The narrow steel brushes and specially designed spray localizers permit the treatment of small pits and areas, such as the nasolabial fold, that are otherwise not readily accessible. The method constitutes an improvement over the sandpaper technique also in that it eliminates the potential risk of the later development of silica granuloma. Then too, this operation is performed in the office; general anesthesia is not required.

APPARATUS AND TECHNIQUE

The abrading device consists of a motor mounted on a stand to which a flexible shaft is attached. At the end of the shaft is a handpiece with provisions for inserting and tightening the wire brush mandrel. The speed of rotation of the brush is controlled by a foot-operated rheostat.

The operation should be performed in a well-ventilated room and should begin with the application of chilled packs, containing a 5% solution of propylene glycol, on a clean skin (freshly shaved, cosmetics removed) for about 20 minutes. The scalp is covered with an operating-room cap or bathing cap, as hairs entangled in the brush may snap the spring in the sensitive handpiece. Cotton is plugged into the ear canals and into the nostril on the side to be planed. The lips are greased with petrolatum, the eyelids covered. The base of each pit is dotted with gentian violet solution to serve as a guide for planing depth. A course spray of ethyl chloride is then directed to an area with scars; simultaneously a current of air from a blower or fan is directed to the area to hasten both the evaporation of the ethyl chloride and the freezing of the skin. The preferred blower is mounted on a stand and has a flexible elongated nozzle, so that the air-flow direction can be "pinpointed" on the area to be treated. The area freezes white almost immediately, and the skin becomes anesthetized and rigid. To render the surface flat, the operator then applies slight tension to the skin with a wooden tongue blade held with his free hand. The scars are then abraded by the motor-driven wire brush, which is manipulated in short strokes with a firm hand in a direction vertical to the rotating direction of the brush in order to avoid grooving. The procedure is repeated, progressing from area to area, until all the scars have been planed (until all the gentian violet has been brushed away).

Such matters as to how much pressure to apply, the width of the brush, the angle of the blades, and the number of "abrasions" are determined entirely by experience. Blood-oozing from the frozen sites is minimal and dries quickly. A sterile dry dressing is applied until the oozing stops, and the entire face then is dressed with Telfa dressings (fabric plus plastic) applied rather firmly. Some operators apply dressings of sterile petrolatum, others employ antibiotics in dressings and/or by mouth. We instruct patients to remove the dressings, which become blood-tinged, after 24 hours; others instruct the patients to remove them after a few hours or not for three or four days. No further dressings are required. Most patients find the procedure to be painless, although a few, after the planing and before the bandages are applied, complain of a burning sensation much like that of a skinned knee. The younger patients "take it in stride"; the older ones speak of an "emotional experience," particularly when the bandages are removed, because the sight is frightening to some. The skin is red and markedly swollen—enough to shut the eyes in some cases—and covered with dried blood and scabs as though the face had been burned severely. The scabs drop off in 7 to 10 days. After the second week, patients usually return to their normal activities, although a fastidious person may choose to remain home for another week because of the redness. The edges of the scars begin to recede by the fourth week, and the improvement continues steadily for several months, so that patients usually look their best about six months after the operation.

The results of treatment depend a great deal upon the skill of the operator and the depth and shape of the scars. Flat superficial scars respond better than do deep-pitted so-called ice-pick type of scars or the wide, flat confluent scars that produce an undulating appearance of the skin. Unfortunately the latter types occur all too often and produce the most severe cosmetic defect, so that persons who need help most get it least. The results are seldom dramatic, although the majority of patients are pleased with the cosmetic improvement. In many cases the improvement in the patient's well-being is so striking that it leads us to believe that we have taken too lightly the importance to the patient of acne scars. The treatment may be repeated several times at intervals of four to six months if necessary. The age of the patient is not important, although results seem to be better in younger persons. The presence of a few acne lesions should not interfere with the treatment.

The procedure may also be used for the treatment of scars from herpes zoster, chickenpox, or smallpox. Scars from chickenpox, because of their flattened shape, respond exceptionally well. It has been suggested also for the treatment of tattoo marks, keratoses, nevi, and other benign growths, but there are better methods of treatment for such lesions.

COMPLICATIONS

The complications that are occasionally observed are relatively unimportant. On rare occasions impetigo, which is readily controlled by treatment with antibiotics, develops in the second week. More often, milia may appear some weeks later. These disappear in time; emptying them does hasten their involution. In exceedingly rare instances, postoperative redness has persisted for several months instead of for the usual three or four weeks. This may result from excessive refrigeration, overexposure or premature exposure to sunlight after the operation, or overly vigorous cleansing. In rare cases hyperpigmentation at the edges of abraded areas, or as a mottling of the entire abraded area, develops and persists for a while. The appearance of eczematous patches has been recorded, and the much dreaded complication of hypertrophic scar development has also been recorded, albeit rarely. We have encountered five cases in which small hypertrophic scars developed, but in each case the scars were readily flattened by treatment. We have heard of larger "keloids" developing but have seen no authentic reports of such cases.

MODIFICATIONS

In recent months we have replaced ethyl chloride with the freezing agent Freon 114 (Frigiderm, dichlorotetrafluoroethane) because, unlike ethyl chloride, it is nontoxic, has no general anesthetic properties, and is nonflammable and nonexplosive—in short, as Wilson has said, "It does the work of ethyl chloride without the dangers of ethyl chloride." [2] An additional advantage is that ethyl chloride disperses the gentian violet and thus may mask the field of operation, whereas Freon 114 does not. Then, too, with Freon the sometimes nerve-racking noisy blower becomes an unnecessary piece of equipment.

Freon is supplied in spray-type containers. At the annual meeting of the A. M. A. on June 6, 1955, Wilson demonstrated a "jet spray," not yet available, which is attached to the planing handpiece and receives the refrigerant through a tube from a container mounted on the motor standard. It is equipped with finger-button controls, which make it a one-man, timesaving device. A "pneumatic freezing unit" has been designed by LeVan [3] to deliver the ethyl chloride spray under a stream of compressed air, the procedure being controlled by a foot pedal. Eller [4] has employed a faster motor and instead of a steel wire brush uses an emory stone wheel first suggested by Schreuss.

Some physicians routinely use analgesics and antibiotics preoperatively and postoperatively. We employ these measures only in selected cases. Some operators treat only a small area at a time, in order not to confine the patient, but the results, in our experience, are more satisfactory when the entire face is treated at one time.

COMMENT

The tremendous interest in the dermabrasion technique shown by both physicians and patients reveals the amazing importance and often-exaggerated importance of a scarred skin to a person's emotional well-being. In the beginning, and understandably, practically every patient who sought treatment for scars was treated. The limitations of the treatment were not fully realized, and inevitably the technique was both abused and misused, and most unfortunate were the unduly glowing accounts of the treatment that appeared in some newspapers and popular magazines.

The operation to flatten scars is a cosmetic procedure, not a lifesaving one; therefore, careful selection of patients is as ethical a plan as it is wise. To treat a patient who expects a perfect result is to invite unpleasant consequences, because the results of treatment are usually good rather than dramatic. It is unwise also to treat unstable persons who attribute all of their inadequacies to the scars, although on two occasions, at the request of psychiatrists, we have treated patients with scars from neurotic excoriations with happy results. As has been mentioned, though they can be helped, the results are not what one hopes for when the scars are deep, narrow, and sharp-edged, the so-called "ice-pick" type scars, or when they are wide and confluent, causing an undulating appearance. Then, too, this type of skin usually is riddled, especially in the central oval portion of the face, with patulous pores, and wide pores cannot be improved by treatment. Results from treatment are more satisfactory on the face than on the chest, shoulders, back, or neck. Scars of recent origin apparently respond better to the treatment than do old scars. We prefer, for the time being, not to treat youngsters whose acne is still in the active stage. For one or another of these reasons we now reject two to three out of five persons who apply for the treatment.

Before treatment it is important to discuss the problem thoroughly with the patient in the presence of a relative and to stress, when necessary, that the results may fall somewhat short of the patient's expectations. The whole experience will be more pleasant if the patient is sufficiently intelligent and emotionally conditioned to be content with improvement, even after two or three operations, rather than complete cure—and, incidentally, it is tempting fate to try to foretell the amount, percentage-wise, of improvement to be expected from treatment. It is better for a patient not to decide on an operation during the first interview, for it is an emotional experience and should be considered calmly and carefully.

CONCLUSIONS

A realistic consideration of the dermabrasion technique indicates it to be the best treatment yet devised for the improvement of acne scars. Although the treatment does not produce "miraculous new skin," superficial flat scars sometimes respond with striking results; other types are benefited in various degrees. In general, the majority of patients are satisfied with the results; occasionally, the results are more pleasing to the patients than to the physician. Unfortunately, not every patient with acne scars can be helped sufficiently, but, if particular care is exercised in the selection of the patients, a great deal of good can be done for a great many persons, cosmetically as well as emotionally.

STATEMENT BY THE BOARD OF TRUSTEES

REASONS FOR A. M. A. STAND ON COMPULSORY SOCIAL SECURITY COVERAGE OF PHYSICIANS

The current position of the American Medical Association relative to the inclusion of physicians under the Social Security Act, as set forth in the proceedings of various meetings of the House of Delegates, especially those since 1949, can be stated briefly as follows: Physicians are definitely opposed to compulsory coverage under Title II (Old-Age and Survivors Insurance) of the Social Security Act, but are not opposed to voluntary coverage thereunder. Reasons for this position are stated below, not necessarily in order of importance.

(1) Since Bismarck introduced socialized medicine in Germany three quarters of a century ago, the threat of socialized medicine through the extension of so-called social insurance has been ever-present in Western civilization. One nation after another has succumbed to the drive to extend the compulsory system of taxation called social insurance to finance a vast program of medical and hospital care for taxpayers and nontaxpayers. The history of developments in this field in foreign countries has alerted the medical profession to the usual consequence of a federal social security program.

(2) Most self-employed physicians do not retire; nor do they have any intention during their early professional lives of retiring at a fixed age. Currently about six physicians out of seven in the age group 65-75 are engaged in the active private practice of medicine. This is so because they can still utilize their accumulation of knowledge and skill to minister to sick people and because sick people still want these physicians to serve them. It has often been said that the only way a self-employed physician can actually retire is to move out of the community in which he has practiced. This observation was published in the printed hearings of the Senate Finance Committee on Social Security Amendments dated July 6, 1954. Thus, the provisions of the Old-Age and Survivors Insurance sections of the act simply do not fit the economic pattern of the self-employed physician.

(3) Since most self-employed physicians do not retire, the tax imposed upon them by coverage under O. A. S. I. would be unjust and unreasonable. They would be required to pay the tax long after most gainfully employed persons in other occupations have ceased to pay it and have started to draw their pensions. The amendments to the Social Security Act of 1954, which, in part, lowered the minimum age from 75 to 72 after which unlimited earnings do not prevent payment of pension benefits, reduced this inequality to some extent but did not eliminate it.

(4) The program is not really an "insurance" program as it is called. According to a published report of the Subcommittee on Social Security of the House Ways and Means Committee, 83rd Congress, retired beneficiaries under O. A. S. I., as of December, 1952, have received and/or would receive, on the average, pension benefits equal to approximately $24 for each fifty cents paid in during the working years of their lives. This ratio was again raised, to about $30 for each fifty cents paid in, by the 1954 amendments to the Social Security Act.

(5) Physicians as a group do not seek federal charity. The amount of the windfall benefit under Title II of the Social Security Act is not difficult to estimate. With a reduction since 1900 of almost 30% in the mortality rate between the ages of 65 and 75, the average remaining lifetime at age 65 is now about 153 months for a man and 180 months for a woman. By simple arithmetic it can be seen that paying a retired man, on the average, 153 monthly checks of $100 each, amounts to $15,300; paying a woman 180 monthly checks of $100 each, totals $18,000. These amounts do not cover survivorship benefits. If a man started to pay Social Security taxes on January 1, 1937, and paid taxes every month, he would not have paid more than $753 by the end of 1955. With the additional $753 paid by his employer the combined total is about one tenth of the $15,000 needed to finance the primary pension under O. A. S. I., let alone survivorship benefits for his widow and children. The differences between what he and his employer paid in and the cost of his pension to the government is, of course, the extent of his windfall benefits.

The deficit of $13,500 will be paid by younger taxpayers and future generations. The argument that we should accept these windfall benefits because almost every eligible citizen will has little appeal to physicians when their basic struggle is to preserve the free practice of medicine.

(6) In preference to compulsory coverage under the Social Security Act, the medical profession is giving its active support to the Jenkins-Keogh bills. These bills (H. R. 9-10, 84th Congress) would amend the Federal Internal Revenue Code so that self-employed physicians and others would have the same tax deferment advantages on the amounts set aside for retirement as are now enjoyed by the officers and employees of corporations, associations, and others.

The bills would provide prepaid pensions for all who are willing to save. We believe that our country is so diversified and that people earn their livings under so many different conditions that it is wise public policy for the Congress to provide a flexible pension system for the self-employed and to permit the pensionless employed to participate in the same voluntary program.

Contrariwise, we consider it incompatible with the free enterprise system for a group to be compulsorily covered under a governmental system of old age benefits when that group strongly opposes such coverage.

SECOND INJECTION OF POLIOMYELITIS VACCINE

When poliomyelitis vaccine was packaged for distribution some months ago, directions for use were included in the packages. These directions are now causing some confusion, since the original package inserts may not contain current recommendations but rather the schedule used in the 1954 field trial. Actually, the situation can be simply stated so far as most recent recommendations from Dr. Jonas Salk are concerned. They are in line with statements appearing in the August 6, 1955, issue of THE JOURNAL, pages 1244-1246. The second dose can be given as early as two weeks after the first, although the optimal time is felt, by Dr. Salk, to be four to six weeks. The third dose should be given approximately seven months or longer after the second dose. Southern physicians, of course, may have to adjust their schedules because the poliomyelitis season arrives earlier there than in the northern part of the country. So far as is known, there is no reason why the vaccine that is now available cannot be used, if such use is indicated, regardless of when it was prepared and regardless of the directions for use inside.

Physicians who have given two doses one week apart need not give additional inoculations but should give the third dose at seven months, or longer, after the second. Those who have given three doses, over a period of five weeks, as recommended in the package enclosures, should plan on a booster dose not less than seven months after the last dose in the primary series.

DERMABRASION

Dermabrasion or skin planing is an improved technique based on the centuries old principle that abrasion is a means of smoothing the scarred skin. It was first reported in medical circles several years ago. Since then experience has accumulated in the use of skin planing, particularly in the treatment of the pits and scars of acne. In spite of enthusiastic and premature publicity, which has distorted the true picture, no conclusive statements on the real significance of dermabrasion can yet be made. However, enough patients with acne scars have been treated and observed for a sufficiently long period to warrant a status report to the Committee on Cosmetics (see this issue, page 1299).

Enthusiasm for this method should not be discouraged, but its limitations must be clearly understood by the physician and the patient. Dermabrasion can improve skin appearance in many patients; it cannot help others. Often those who need it most obtain the least relief. The careful selection of patients has become a dependable guide to successful results. Consideration of many factors, including the degree and type of scarring and the psychological state of the patient, has led some dermatologists to reject as many as three out of five who seek treatment. In dermabrasion as in other procedures where the improvement of appearance is the goal, success cannot be measured entirely by the physician's objective evaluation. Those who suffer from severe acne scarring and obtain the least skin improvement are often more enthusiastic about results than the less disfigured patient who experiences marked improvement by the physician's standards. Complete dissatisfaction can be expected in those persons who regard their scarred skin as solely responsible for their failures and discontentment in life. An improved skin will not have the magical effect of bringing them the social and economic success that they expect. On the contrary, it removes the excuse the patient has used for his failures. There is a real possibility in such patients that harm will be done by converting a minor psychological disturbance into a severe one.

These experiences in the treatment of acne scars will lead to a better understanding of the usefulness of dermabrasion in other types of scars and blemishes.

LOS ANGELES CONVENTION

The Los Angeles County Medical Association is sponsoring an assembly to be presented at the Biltmore Hotel and the Philharmonic Auditorium in Los Angeles, January 3, 4, and 5, 1956. The theme will be "Eighty-Five Years of Medical Progress." One half day will be devoted to each of six subjects: "Medicine's Role in the Atomic Age," "Modern Concepts in the Utilization of Blood and Blood Products," "Diagnosis and Treatment of Neoplastic Diseases," "Preventive Medicine," "Use and Misuse of Miracle Drugs," and "Management of the Geriatric Patient."

This program may not seem unusual except for the fact that it is tied in with an 85th anniversary; however, there is another feature that may lead to similar interesting developments elsewhere. The county association is sponsoring an event for the public, a Public Health Fair. It will be known as "A Cavalcade of Health and Medical Progress" and will run for 10 days beginning the morning of January 6. The 10 days will be devoted to medical lectures, motion pictures, commercial exhibits with a health story, and scientific exhibits prepared by medical schools, hospitals, clinics, research organizations, and other groups. The Los Angeles School Board has promised its cooperation and is making plans to allow the school children to attend these public meetings en masse. There also is being prepared a special health education program for the teachers, for which they will receive "institute credit." The superintendent of schools has appointed a committee of three physicians from his staff to work with the Los Angeles County Medical Association to develop a program suitable for both student and teacher.

Such a program should provide a stimulating avenue to similar ventures elsewhere. Health fairs or their counterparts have been held in other parts of the country and have been well received. Many will remember, for example, the show for the public following the A. M. A. meeting in Miami in 1954. It is doubtful, however, if local school authorities have ever previously participated to such a degree.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

I have received many letters from men all over the country complaining about the so-called doctor-draft extension for two years. The American Medical Association has been criticized for not protesting more forcibly against this discriminatory law. We did protest, but our protestations were of no avail when at the last minute the doctor-draft provisions were tacked onto the regular draft law. Although vigorous protests were made by us and by many of our friends in Congress, we were only able to accomplish two things: one, the age for induction of physicians was reduced from 51 to 46; and, two, any physician 35 years or older who was or is rejected for a commission in the Medical Corps solely for a physical disqualification became no longer liable under the act. I know for many reasons that there are no more patriotic citizens than the physicians. They object, and I think rightfully so, against this discriminatory legislation in times of so-called peace. War times are different, but we do have the doctor draft extended for two more years whether we like it or not, and the tragedy is that it may again be extended when the present two year period is over. In fact, a doctor draft could become a permanent thing come war or peace. This to me is an alarming situation that the Association must actively combat.

I have questioned many of my friends in the regular medical services, and I had one man high in the regular Medical Corps tell me without any reservations that there would be no Medical Corps in a few years the way things were going at the present time. A big part of the answer to this unusual and rather startling situation is just plain ordinary economics. This particular gentleman pointed out to me that the men who should be the backbone of the regular corps were retiring as soon as they could from the services to go into private practice just when their services were of the utmost value to the government because of their experience and training. The economic situation is so bad at present that it is impossible to recruit good young physicians for the permanent services. The career men in the Army are having a hard time financially, and it is difficult to blame a young man after he serves his time for not applying for a regular commission when he sees what is happening. This is particularly true when he sees the colonels retiring as fast as possible to accept much better paying positions in civilian life.

When I was a youngster it was a very desirable thing for a man to make a career in the armed forces medical services. Competitive examinations were the rule, and the men were very carefully selected. These are the men today who have so splendidly managed the terrific medical problems that have faced our armed forces during the past two decades. In the early days the salaries with the added benefits were somewhat comparable to the rewards of civilian practice. There were of course the added adventure, the educational facilities, and the social advantages. Today the salaries are not comparable with the income in the private practice of medicine nor in the medical positions in schools, clinics, and industry that are available to the older men who are eligible for retirement. The Department of Defense recently set up a task force to study the problem and make recommendations. The American Medical Association is, I know, perfectly willing to help in this task, but the sad state of affairs remains, and changes are neither quickly nor adequately accomplished.

We are the richest country in the world. We spend large sums of money abroad and we spend it at home on all sorts of welfare programs, but we treat all of our armed forces career people abominably. These men are the most important part of our national defense. Their salaries should be proportionate to the magnificent services they render. Their economic position should be such that they can live reasonably well and educate their children without undue worry. Taking into consideration their retirement pay and the benefits that are their right, their salaries should immediately be upped and they should receive somewhere near that which they could earn as civilians with equal duties and responsibilities. This in my book goes for all commissioned personnel in all departments of the armed forces but more particularly to the career medical men.

Unless this is done and done at once I can easily understand my Army friend's statement that in a few years there will be no career Medical Corps. What then? The men and women in the services have to be given preventative and curative medical care. Where will we get the doctors to do this? There is only one answer—the doctor draft. What can we do about it? We can assist the Department of Defense to restudy the whole problem and come up with recommendations. To whom? Congress. What else can we do? We can approve the recommendations when they are economically sound, and we can be of great service to our country by telling our representatives in Congress that this type of legislation is a must. It is one of two things; which do you want—an economically sound career Medical Corps or the doctor draft? Make no mistake—it is one or the other.

Elmer Hess, M.D.
Erie, Pa.

ORGANIZATION SECTION

STUDY CONFERENCE ON LEGISLATION

A study conference called by the American Medical Association to consider methods of informing its membership of certain aspects of pending legislation was held in Chicago, Oct. 22. More than 100 representatives of constituent state medical associations, A. M. A. officers, and members of the Board of Trustees participated in discussions and considered approaches for focusing the public's attention upon the A. M. A.'s viewpoint. H. R. 7225, known as the Social Security Amendments of 1955, includes provision for the payment of monthly cash benefits to the permanently and totally disabled at age 50. The bill, passed by the House of Representatives last summer, will come before the Senate Finance Committee for public hearings early in the next session of Congress.

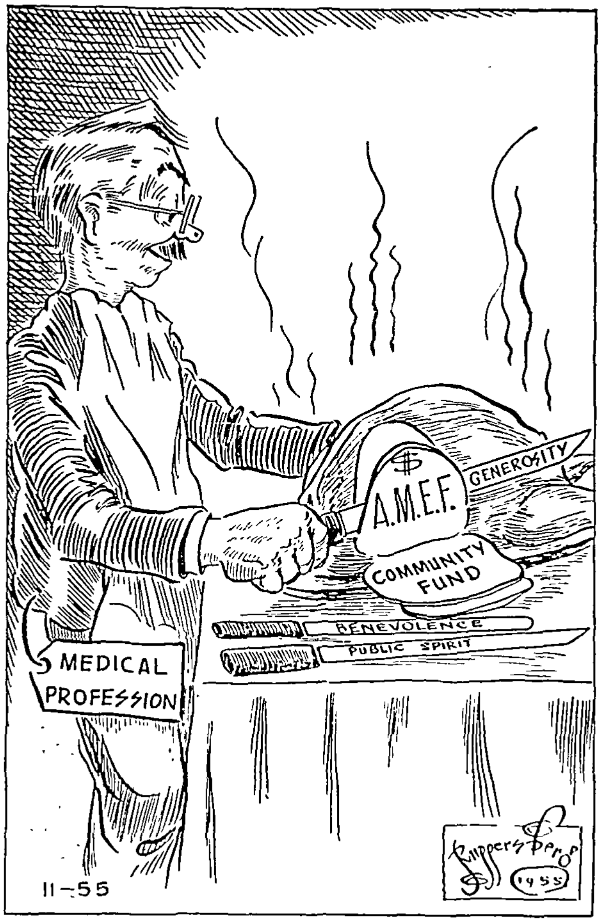
Comments of participants were solicited at the Chicago meeting, and A. M. A. officers and trustees are currently studying these opinions. Dr. George F. Lull, A. M. A. Secretary and General Manager, urged that all medical society representatives who attended the conference send further comments, suggestions, or criticisms to A. M. A. headquarters. He pointed out that the Association is studying the consensus of the state representatives who attended the conference and will proceed in a manner consistent with the views of the majority.

Giving the official address of welcome at the conference, Dr. Gunnar Gundersen, chairman of the Board of Trustees, said: "Our great aim should be to join with other groups and organizations, with the press and other communications media and with responsible leaders of both political parties to separate Social Security and politics. The A. M. A. believes that problems of Social Security should be solved on the basis of sound judgment, an objective analysis of facts, a humane attitude toward human suffering—and not on the basis of political expediency."

Dr. Elmer Hess, A. M. A. President, emphasized that the program to promote a better social security system must be considered a "long range effort," looking forward to 1958, 1960, even to 1962. He also stressed that study of social security legislation will require close cooperation and mutual activity at the national and local levels.

THE BOSTON MEETING

The School of Medicine Alumni Association of Boston University will hold an informal reunion at the Sherry-Biltmore Hotel in Boston Tuesday evening, Nov. 29. Dinner is scheduled for 7 p. m., with a social hour starting at 6 p. m. Tickets are $5 each, and wives and friends are invited.



"How're ya fixed for blades?" (Reprinted from the *Bulletin of the Columbus* (Ohio) *Academy of Medicine.*)

FEDERAL MEDICAL LEGISLATION

First Session, 84th Congress

Agency for the Handicapped

Congressman Diggs (D., Mich.), in H. R. 7207, and Congressman Staggers (D., W. Va.), in H. R. 7465, would establish a federal agency for the handicapped in the United States Department of Labor. To this would be transferred the Office of Vocational Rehabilitation from the Department of Health, Education, and Welfare, together with other governmental functions having to do with the handicapped. This measure, identical with numerous other measures previously reported, was referred to the Committee on Education and Labor.

Prepared by the Washington Office of the American Medical Association.

COUNCIL ON NATIONAL DEFENSE

RESULTS OF SURVEY OF PHYSICIANS SEPARATED FROM ACTIVE MILITARY SERVICE

The Council on National Defense, in July, 1952, initiated a continuing opinion survey of physicians released from active military service. Through an agreement with the military services, the Council is currently being furnished the names and addresses of these physicians. In turn, the Council requests these physicians to complete a questionnaire primarily designed to obtain pertinent information acquired during their tour of duty concerning the utilization of physicians and medical staffing conditions in the services. The results of these surveys are used as the basis of conferences with representatives of the Department of Defense and the armed forces, since the questionnaire also calls for comments and suggestions of ways to further improve the medical corps as well as ways and means whereby organized medicine can be of greater assistance to military physicians. This report covers the period from July 1, 1954, to Dec. 31, 1954, during which time a total of 2,373 questionnaires was distributed. Of these, 1,500 completed forms were returned to the Council, representing a 63% response.

AGE DISTRIBUTION BY BRANCH OF SERVICE

Of 1,500 physicians replying, 783 men were between the ages of 30 and 34 years; 465 between 25 and 29 years; 200 between 35 and 39 years; and 52 were over 40 years of age. The largest number of physicians (639) were in the Navy, and 512 and 348 were in the Army and Air Force respectively. The Army had the largest number in the 30-34 age group and the 40-and-over age group. Of those in the 25-29 age group, 225 were in the Navy and 134 in the Army.

PHYSICIANS' EVALUATION OF STAFFING CONDITIONS

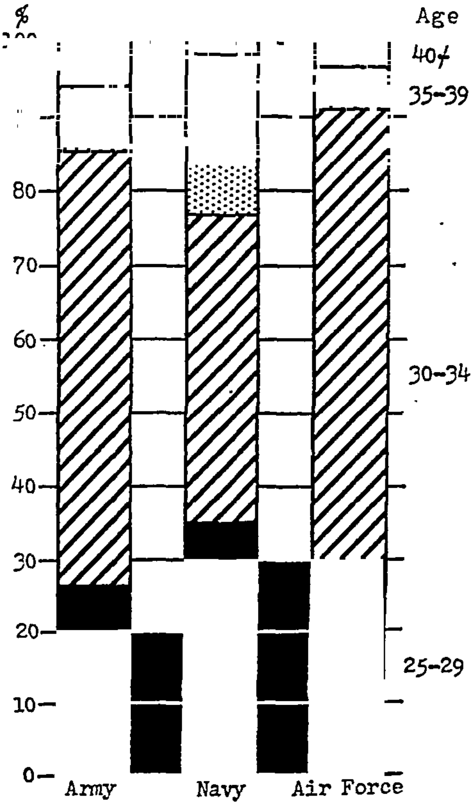
One of the questions was designed to obtain the opinion of physicians as to staffing conditions of nurses, enlisted medical personnel, physicians, dentists, and others at those units in which service was performed by the physician. The tabulation of this multiple-answer question indicated that in the Army replies of overstaffing totaled 389, understaffing 434, and adequate staffing 1,136. In the Navy, overstaffing was shown at 570, understaffing at 466, and adequate staffing at 1,334. The Air Force tabulation revealed 284 replies of overstaffing, 413 of understaffing, and 684 of adequate staffing. Table 1 reflects, in detail, the percentages relative to overstaffing, understaffing, and adequate staffing conditions.

DISTRIBUTION OF PHYSICIANS BY RANK AT TIME OF DISCHARGE

The majority of physicians in all three branches of the service, at time of separation, held the rank of first lieutenant or lieutenant junior grade. The survey indicates that 51.1% of those who reported were in the lowest rank, while 45.4% held the rank of captain or lieutenant senior grade. There were only 3.5% with higher ranks. By services, the Air Force had 10.1% at the first lieutenant rank and 88.2% at the captaincy level. The Navy had the highest percentage in the lowest rank, with 85.6% at the lieutenant junior grade level. Table 2 reflects, by branch of service, these percentages.

NUMBER OF YEARS SINCE GRADUATION

The survey indicated that about half of those replying (764, or 50.9%) were graduated from medical school between the years 1945 and 1949; the second largest group, 416, or 27.7%, were graduated in 1950 or later; and the third group in order, 298, or 19.8%, were graduated between 1940 and 1944. Only a small number, 15, or 1.0%, were graduated before 1940. Six failed to answer the questions (table 3).



Age distribution of physicians by branch of service.

YEARS OF INTERNSHIP AND RESIDENCY

By far, the majority of those responding, 1,331, or 88.8%, had one year of internship training, while 350, or 23.3%, had three years of residency; 260, or 17.3%, had one year of residency; 244, or 16.3%, had two years of residency; and 334, or 22.3%, had no residency training. Table 4 shows this tabulation in more detail.

OCCUPATION AT TIME OF ENTERING SERVICE

A majority of the physicians who served in the Army, Navy, and Air Force were engaged in residency training at the time of entrance into active military duty. The largest group in the naval service was engaged in residency training, with specialty practice second. In the Army group, specialty practice was second, while, in the Air Force, internship and general practice tied for second, with specialty practice a very close third (table 5).

NUMBER OF PHYSICIANS HOLDING BOARD CERTIFICATES BY FIELD OF SPECIALIZATION

Table 6 shows the detailed numbers, by specialty and by branch of service, of physicians holding board certificates. Of the 270 persons responding to this question, 87 holding board certificates were in the Army, 139 were in the Navy, and 44 were in the Air Force. The specialties covered over 18 different fields, of which the largest was surgery, the second largest was pediatrics, and the third largest internal medicine. By branch of service, a total of 17.0% of those responding in the Army, 21.8% of those in the Navy, and 12.6% of those in the Air Force had certificates. For the three services, 18.0% of those responding had board certificates.

RESERVE STATUS

Most of the physicians who replied indicated that they still had their reserve commission. The percentage who retained their commission was higher in the Navy, with the Army second and Air Force last. These percentages are reflected in table 7.

GOVERNMENT MEDICAL EDUCATION RECEIVED

Of the 1,499 physicians in the Army, Navy, and Air Force who completed the questionnaire, a total of 1,033 stated that they had received assistance in their medical education from the government. There were 466 who said they had received no government assistance. The largest single group receiving government assistance was under the Navy V-12 Program, while the next largest number received assistance under the Army Specialized Training Program. The GI Program accounted for the third largest group, while several listed a combination of various programs. Table 8 shows percentages in detail.

TABLE 2.—*Distribution of Physicians by Rank at Time of Discharge*

TRAINING RECEIVED WHILE IN SERVICE

Of the 1,500 who returned a completed questionnaire, approximately one-third did not respond to the question concerning the additional training or experience received while in the military service. Of those responding, 412 who served in the Army, 276 in the Navy, and 251 in the Air Force indicated they received additional training or experience in service schools. The Medical Field Service School accounted for the largest number, while the School of Aviation Medicine and the Amphibious Forces Training School were next in order of size. Table 9 indicates the number and percentage distribution of physicians by type of training received and by branch of service.

PHYSICIANS' EVALUATION OF MEDICAL MILITARY TRAINING

The great majority of the physicians filling out the questionnaire felt that all important features of medical military training had been satisfactorily covered. A small percentage indicated the training was unsatisfactory but gave no specific reasons. Others stated reasons why they considered their tour of service unsatisfactory. It should be pointed out that this was a multiple-answer question. According to services, the response from the Army was 469, from the Navy 513, and from the Air Force 317. Table 10 indicates percentages by branch of service.

PHYSICIANS' EVALUATION OF ASSIGNMENT

A large majority of the physicians indicated that they were properly assigned; however, a less decisive majority in the Army and Air Force responded favorably to the question as to whether they were properly rotated.

TABLE 6.—*Number of Physicians Holding Board Certificates by Field of Specialization*

	Army	Navy	Air Force
Pediatrics	14	16	11

Dropped commission	51.9	20.2	62.6
No response	0.4	1.4	0.6
Total	100.0	100.0	100.0

TABLE 8.—*Percentage Distribution of Physicians by Type of Governmental Medical Education Received*

	Army, %	Navy, %	Air Force, %
Army Specialized Training Program	23.6	10.0	20.7
Navy V-12	12.5	62.6	21.9
GI Bill	11.7	5.5	8.9
Navy V-12 and GI	10.4	1.0	10.9
Other	0.8	0.6	1.4
	59.0	79.7	63.8
No assistance	41.0	20.3	36.2
Total	100.0	100.0	100 0

A more decisive majority in the Navy, however, responded favorably to the question as to whether they were properly rotated. Tables 11 and 12 show these percentages by branch of service.

TYPES OF PATIENTS TREATED

One of the questions was designed to determine the percentage of time devoted by physicians to military personnel, dependents of military personnel, and administrative duties, both at domestic and overseas stations. Many of the respondents neglected to answer the question, and still others answered it only in part. Tables 13 and 14 reveal these percentages in detail.

TYPES OF NONMILITARY MEDICAL CARE PROVIDED

The type of medical care most frequently performed by medical officers for nonmilitary persons was outpatient care. For the Army, "other specialty services" was second in order of frequency, with surgery the third in order. For the Navy and Air Force, obstetrics and gynecology was second in order of frequency, with "other specialty services" the third in order for the Navy and pediatrics the third for the Air Force. Table 15 shows the percentage and types of care.

DUTIES THAT COULD HAVE BEEN PERFORMED ADEQUATELY BY OTHER PERSONNEL

A total of 1,380 physicians answered the question pertaining to duties that could have been performed by other personnel; 120 physicians did not reply of this number, 636, or 46.1%, stated that their duties could not have been performed adequately by other personnel, while 744, or 53.9%, felt their duties could have been performed by other personnel. The 744 physicians who responded to this multiple-answer question in the affirmative gave detailed information as shown in table 16.

PHYSICIANS WHO WOULD VOLUNTARILY REMAIN IN SERVICE

In response to the question relative to military service beyond the obligated tour of duty, 373 physicians indicated they would not be willing to stay in military service for more than their two years of service under any circumstances. A total of 816 physicians indicated they would serve an additional period under certain conditions. There were 311 who failed to reply to the question. Table 17 reflects the reasons or conditions under which an additional period of service would be acceptable.

SUGGESTIONS FOR IMPROVEMENT OF SERVICE GIVEN BY MEDICAL ASSOCIATIONS TO MILITARY PHYSICIANS

A total of 720, or 48.0%, responded to the question concerning the role of national and local medical associations in maintaining closer contact or rendering better service to their members who served as physicians in the armed forces. Of these, 347 had no suggestions. The suggestions of the remaining 373 physicians are tabulated in table 18.

MEDICAL NEWS

CALIFORNIA

Course in Electrocardiography.—The University of California Extension will offer a course in electrocardiography, Wednesdays and Fridays, 7:30-9:30 p. m., from Nov. 30 to Dec. 16 in room 2276 of the Chemistry-Geology Building on the U. C. L. A. campus. The course will stress primarily the features of unipolar electrocardiography and will consist of lectures with lantern slides. Instructor will be Dr. Morley J. Kert, assistant clinical professor of medicine at U. C. L. A. Fee for the course is $20. Request for information should be made to Dr. Thomas H. Sternberg, Assistant Dean for Postgraduate Medical Education, University of California Medical Center, Los Angeles 24.

Society News.—Officers for 1955 of the Los Angeles Obstetrical and Gynecological Society include Dr. Samuel M. Martins, Los Angeles, president; Dr. Ralph H. Walker, North Hollywood, vice-president; and Dr. Walter C. Rogers, Pasadena, secretary-treasurer.——New officers of the Allergy Foundation of Northern California include: Dr. M. Coleman Harris, San Francisco, chairman of the board of governors; Dr. Grace M. Talbott, San Francisco, vice-chairman; and Dr. Albert P. Rowe Jr., Oakland, secretary-treasurer.——The Los Angeles Radiological Society recently elected Dr. George F. Jacobson, Los Angeles, president; Dr. Hubert J. Prichard, Long Beach, vice-president; Dr. Samuel C. Kahlstrom, Los Angeles, treasurer; and Dr. Richard A. Kredel, Pasadena, secretary.

Dr. Bullock Honored.—Dr. Lewis T. Bullock, chairman, research committee, Los Angeles County Heart Association, and an associate clinical professor of medicine, University of Southern California School of Medicine, Los Angeles, was presented recently with a framed scroll bearing more than 100 signatures at a testimonial dinner. The award cited Dr. Bullock's "service on behalf of mankind and selfless efforts in developing the program of research which has made this area one of the leading centers of cardiovascular research." Dr. Paul Starr, head, department of medicine in the University of Southern California School of Medicine, presented the scroll, and Dr. Albert A. Kattus, associate professor of medicine, University of California at Los Angeles School of Medicine, was master of ceremonies. Among the speakers were Drs. Walter E. MacPherson, Gordon E. Goodhart, Stafford L. Warren, Myron S. Prinzmetal, and John S. Lawrence.

CONNECTICUT

Guest Speakers at Hospital.—In its guest speaker program, Saturdays, 11 a. m., the Hartford Hospital presents Dr. Howard A. Rusk, professor of physical medicine and rehabilitation, New York University College of Medicine, and medical consultant to the Rehabilitation Division of the Veterans Administration and the United Nations, who will discuss the dynamic approach to chronic disease Dec. 3; and Dr. Averill A. Liebow, professor of pathology, Yale University School of Medicine, New Haven, who will conduct a clinical pathological conference Dec. 10.

ILLINOIS

Hospital Chosen for Hemoglobin Study.—The Highland Park Hospital has been chosen as one of 125 hospitals in the United States, Canada, and England to participate in research on standardizing tests for hemoglobin.

Cardiologists Meet in Springfield.—Scientific sessions on cardiovascular diseases will be conducted by the Illinois Heart Association in cooperation with the Illinois Department of Public Health and the Sangamon County Medical Society, Dec. 1, at the Hotel St. Nicholas, Springfield. Dr. Arnold S. Moe, East St. Louis, will be chairman of the afternoon session, at which the following guest presentations will be made:

Cardiac Surgery, William S. Dye Jr., Chicago.
Diagnosis and Management of Rheumatic Fever, Bernard A. Schwartz, Cincinnati.
Coronary Heart Disease, Paul S. Barker, Ann Arbor, Mich.
Instrumental Diagnosis of Heart Disease, E. Grey Dimond, Kansas City, Kan.

At 4:15 p. m. the guest speakers will participate in a panel discussion moderated by Dr. Edward W. Cannady, East St. Louis. A social hour, 5:30 p. m., will precede the dinner session; at which Dr. Stanley L. Levin, Danville, president, Illinois Heart Association, will serve as chairman and will deliver an address, "Your Heart Association in Action." Greetings will be extended by Dr. David J. Lewis, Springfield, president, Sangamon County Medical Society. Dr. Kenneth G. Kohlstaedt, Indianapolis, the featured speaker, will have as his topic "Management of Hypertension."

Chicago

Dr. James Miller Goes to Michigan.—Dr. James G. Miller has been appointed professor of psychiatry and head of the new Mental Health Research Institute, University of Michigan Medical School, Ann Arbor. Dr. Miller has been chairman of the department of psychology and of the committee on behavioral sciences at the University of Chicago since 1951.

Society News.—Newly elected officers of the Chicago Council of Child Psychiatry include: Dr. Irene M. Josselyn, president; Dr. Adrian H. Vander Veer, president-elect; and Dr. Harry M. Segenreich, secretary-treasurer.——The Dr. Jerome D. Solomon Memorial Research Foundation will present "A Night for a King" at the Conrad Hilton Hotel, Dec. 10, 8 p. m. Reservations ($15 per couple, including dancing, entertainment, and midnight supper) may be made through the reservation chairman, Mrs. David Berke, 3172 N. Sheridan Road, Chicago 14. Irv Kupcinet, Sun-Times columnist, will serve as master of ceremonies.

Death of Carl Moore.—Carl R. Moore, Ph.D., an authority on the biology of sex and chairman of the University of Chicago department of zoology, died Oct. 16 in Albert Merritt Billings Hospital. Dr. Moore, who began his studies before sex hormones were isolated, contributed to their isolation. His work on the effect of hormones aided in the development of treatment for prostate cancer in men and breast cancer in women. In 1950 he received the fifth scientific award of the American Urological Association and last June was awarded a medal by the Endocrine Society in recognition of his distinguished contributions to endocrinology. Dr. Moore had been a member of the faculty of the University of Chicago since 1914.

Dr. Hellebrandt Retires.—Dr. Frances A. Hellebrandt retired Sept. 1 as head, department of physical medicine and rehabilitation, University of Illinois College of Medicine. She will live in Athens, Ohio, where she will devote full time to historical research and scientific writing. Dr. Hellebrandt came to the university in 1951 as a department head. She previously directed the Baruch Center of Physical Medicine at the Medical College of Virginia, Richmond, and was head of the section on physical medicine and associate professor of physiology, University of Wisconsin Medical School, Madison. Succeeding Dr. Hellebrandt as department head is Dr. David I. Abramson, a staff member of the department of medicine since 1946.

Conference on Retirement.—A conference on general retirement problems of industry will be held Nov. 30, 9 a. m.-4 p. m., in the Sherman Hotel under the joint sponsorship of the Chicago Heart Association and the Chicago Association of Commerce and Industry. In the morning the theme will be "Postponing Premature Retirement"; in the afternoon, "Approaches to Retirement." At luncheon Dr. Irving S. Wright,

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

past-president of the American Heart Association and professor of clinical medicine, Cornell University Medical College, New York, will discuss "Chronological Age vs. Biological Age as a Basis for Retirement." The other luncheon speaker will be Meyer Kestnbaum, M.B.A., Chicago, president of Hart, Schaffner & Marx. Luncheon reservations ($3, including tip) may be made through the headquarters of the Chicago Heart Association, 69 W. Washington St., Chicago 2, telephone: FInancial 6-4675.

KANSAS

Refresher Course in Surgery.—The University of Kansas School of Medicine will present its 11th annual postgraduate refresher course in surgery (fee, $60) Jan. 16-19, 1956, at the Kansas University Medical Center in Kansas City. The program will include operative clinics with color television, cine clinics, ward walks, basic sciences in surgery, and surgical treatment of injury and cancer. Program announcements and registration cards can be obtained from the Department of Postgraduate Medical Education, University of Kansas Medical Center, Kansas City 12.

Student Loan Fund.—The Kansas Medical Society has announced the creation of the John M. Porter Memorial Student Loan Fund for junior and senior students at the University of Kansas School of Medicine. Dr. Porter died Sept. 5 during his term of office as president of the society. Contributions may be sent to the society office, 315 W. Fourth St., Topeka, with checks made payable to Porter Memorial. Those who wish to claim tax exemption for their gifts to the fund may make checks payable to American Medical Education Foundation (535 N. Dearborn St., Chicago 10) with an accompanying note stating that the amount is intended for the John M. Porter Memorial Student Loan Fund at the University of Kansas School of Medicine.

MAINE

Postgraduate Course in Anesthesiology.—Physicians are welcome to attend the postgraduate educational program in anesthesiology offered by the Maine General Hospital, Portland, in the house officers' quarters from 4 to 5 p. m. on the first and third Fridays of each month. On Dec. 2 the lecture will deal with barbiturate poisoning and on Dec. 16 with spinal anesthesia.

MASSACHUSETTS

New England Diabetes Association.—A meeting of the New England Diabetes Association will be held Nov. 28 at 8 p. m. in the Joslin Auditorium of the New England Deaconess Hospital, Boston. Dr. Laurance W. Kinsell, medical director, Alameda County Hospital, Institute for Metabolic Research, Oakland, Calif., will discuss "Hypophysectomy in Juvenile Diabetes with Progressive Vascular Disease." There will also be speakers on surgical and endocrine aspects of this problem.

MICHIGAN

Society News.—The Michigan regional meeting of the American College of Physicians will be held at the Sheraton-Cadillac Hotel in Detroit, Dec. 3. There will be a banquet in the evening. Members of the medical profession are invited, and residents and interns are especially welcome.

Ballim Lecture.—Dr. Irving S. Wright, professor of clinical medicine, Cornell University Medical College, New York, will deliver the annual Max Ballim Memorial Lecture at a dinner sponsored by Sinai Hospital, Dec. 1, at the Sheraton-Cadillac Hotel, Detroit, where he will speak on peripheral vascular disease.

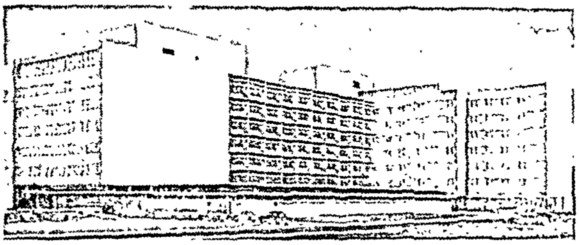
Hearing Research Project.—Wayne University College of Medicine, Detroit, announces a research project involving study of the ears of 60 vertebrate and invertebrate animals to increase understanding of the human ear and its diseases. The study, directed by Dr. Heinrich F. G. Kobrak, professor of otolaryngological research, is being financed by the Beltone Institute for Hearing Research. The study will include the ear of a whale and the hearing mechanism of a cockroach, as well as those of fish, reptiles, Amphibia, birds, and mammals.

MISSISSIPPI

Society News.—The Mississippi Academy of General Practice recently installed Dr. William E. Lotterhos, Jackson, as president and named Dr. Aubrey V. Beacham, Magnolia, president-elect; Dr. Amon K. McMillan, Lucedale, vice-president; and Dr. Robert M. Seawright, Bolton, secretary-treasurer.

Personal.—Dr. James D. Hardy, professor of surgery and director of surgical research, University of Mississippi Medical Center, Jackson, presented "Fluid Therapy in Burns" and "Potassium Metabolism and Therapy" at a postgraduate course on fluid and electrolyte balance at the University of Colorado School of Medicine, Denver, Nov. 10-12.

University Medical Center.—Constructed at a cost of nine million dollars, the University of Mississippi Medical Center, Jackson, was dedicated Oct. 24. The center houses, in one seven-story plant, a teaching hospital, outpatient clinic, research facilities, library, school of nursing, and the school of medicine. It was begun in 1950, when the state legislature appropriated funds, later augmented by Hill-Burton and Hinds County money. Faculty and physical equipment have been transferred from the two-year medical school at the University of Mississippi in Oxford to the new center. The two wings of the 350-bed teaching hospital, activated July 1, form the crossbar of the T-shaped building with the medical school, extending mid-centrally from the hospital section, forming the stem. Floor space is slightly over 10 acres.



Medical Center in Jackson.

MISSOURI

Dr. Lowry Appointed Dean.—Dr. Oliver H. Lowry, head of the department of pharmacology, Washington University School of Medicine, St. Louis, has been named dean to succeed Dr. Carl V. Moore, who resigned to devote full time to research and teaching.

Hospital News.—The new $1,580,000 Renard Hospital, the psychiatric unit of Washington University-Barnes Medical Center, St. Louis, was dedicated Oct. 10 at the medical center. Construction of the new seven-story, 100-bed hospital was begun in 1952 with the aid of Hill-Burton funds.

Personal.—Dr. Daniel L. Sexton, associate professor of medicine, St. Louis University School of Medicine, is the recipient of the 1955 Distinguished Service award given by the Mississippi Valley Medical Society to a member "who has rendered unusual and distinguished service to the medical profession." Dr. Sexton is president of the St. Louis Medical Society.

Society News.—At 8:30 p. m. Nov. 29, the St. Louis Medical Society will present a panel, "Modern Management of Pulmonary Tuberculosis," with Dr. Paul Murphy as moderator and Dr. Alfred Goldman and Dr. Thomas H. Burford (by invitation) as participants. On Dec. 20, 8:30 p. m., "Simple Mastectomy and Irradiation Therapy in the Treatment of Cancer of the Breast—An Evaluation of Dr. McWhirter's Method Based on Personal Study of His Cases" will be the topic of Dr. Lauren V. Ackerman, professor of surgical pathology, Washington University School of Medicine, St. Louis.

NEW YORK

Albert Research Institute.—The Isaac Albert Research Institute, named in honor of the president of the Jewish Chronic Disease Hospital at Brooklyn, has been established at the hospital to promote the development of research laboratories and improve the facilities for studies in the field of chronic diseases.

Part-Time Physicians Needed in Chest Clinics.—The health department plans to open new chest clinics in the Bronx and in Brooklyn. Applications for part-time positions may be obtained by writing to the Bureau of Tuberculosis, 125 Worth St., New York 13. Pay for a three-hour session is $15.

Brooklyn Doctors' Symphony Orchestra.—Physicians, dentists, and others engaged in allied professions are invited to become members of the Brooklyn Doctors' Symphony Orchestra, of which Dr. Jacob Leffert is president. Rehearsals are held every Wednesday at 8:30 p. m. in the auditorium of the Brooklyn High School for Home Making, 901 Classon Ave. For details call Miss Ethel Leitman, secretary of the orchestra, at SLocum 6-2252.

Hospital News.—Sister Mary Aquinas, superintendent of St. James Mercy Hospital, Hornell, was recently honored by Hornell and area residents on the occasion of her golden jubilee. Honored with her was Sister May de Sales, who came to the hospital 55 years ago. Sister Aquinas supervised the maternity department for 29 years, rose to be administrator, and during her administration added the hospital's million dollar wing. The 35-bed hospital of 1905 is now a modern 152-bed hospital.

University News.—Albany Medical College, Albany, announces the following promotions in the department of psychiatry: from assistant professor to associate professor, Dr. Frederick D. McCandless; from instructor to assistant professor, Dr. John D. LaTendresse; from assistant to instructor, Dr. Janis L. Best.——Dr. Stanley M. Ball, assistant neurologist at the Neurological Institute of the Columbia-Presbyterian Medical Center, New York City, has been appointed neurology instructor at Albany Medical College, Albany.——Dr. Richard C. Troutman, assistant professor of clinical surgery (ophthalmology) at Cornell University Medical College, New York City, has been named to the joint post of professor of ophthalmology at the State University of New York College of Medicine at New York City in Brooklyn and director of ophthalmology at the Kings County Hospital, Brooklyn, both on a part-time basis. Dr. Troutman has been affiliated with New York Hospital, Manhattan Eye, Ear and Throat Hospital, New York City, and the Payne Whitney Psychiatric Clinic, New York City.

New York City

Wechsler Lecture.—The first Israel S. Wechsler Lecture will be given on the evening of Dec. 2 at the Mount Sinai Hospital by Dr. John F. Fulton, Sterling Professor of the History of Medicine, Yale University School of Medicine, New Haven, Conn. Dr. Fulton will present "Some Historical Backgrounds of Clinical Neurology" at 8:30 p. m.

Bela Schick Lecture.—The Bela Schick Lecture, "Malformations: Some New Studies of an Old Problem," will be delivered by Dr. Rustin McIntosh, Carpentier Professor of Pediatrics, Columbia University College of Physicians and Surgeons, New York, at 8:30 p. m., Nov. 30, in the Blumenthal Auditorium of Mount Sinai Hospital (Fifth Avenue at 99th Street).

Animal Care Panel.—The Animal Care Panel, an organization of investigators, administrators of animal quarters, animal breeders, and others interested in the care of experimental animals, will meet Dec. 1-2 at the Henry Hudson Hotel (353 W. 57th St.). The program will comprise papers dealing with the physiology and behavior of laboratory animals, their diseases, nutrition, and related problems.

Thomas Salmon Lecture.—"Psychiatric Education and Progress" will be the subject of the 1955 Thomas William Salmon Lecture by Dr. John C. Whitehorn, Nov. 30 (2:30 and 8:30 p. m.) at Hosack Hall of the New York Academy of Medicine. Dr. Whitehorn, professor of psychiatry, Johns Hopkins University School of Medicine, Baltimore, is a former president of the American Board of Psychiatry and Neurology and of the American Psychiatric Association.

Pediatricians Honor Bret Ratner.—At the annual meeting of the American Academy of Pediatrics, the section on allergy presented to Dr. Bret Ratner a scroll with the following inscription: "By unanimous vote of the Section on Allergy of the American Academy of Pediatrics, assembled in Chicago at the Twenty-third Annual Meeting of the Academy, this Scroll is awarded to Bret Ratner, M.D., as an expression of gratitude and appreciation for his untiring services in advancing Pediatric Allergy, As a pioneer investigator and teacher, As organizer of the Section on Allergy and its first Chairman, For his successful efforts in obtaining recognition by certification for Pediatric Allergists in the Subspecialty of Pediatric Allergy."

Conference on Heart Disease.—The New York Heart Association will hold an all-day conference on rheumatic fever and heart disease Nov. 29 at the Biltmore Hotel. Speakers at the morning session will be:

Maclyn McCarty, New York, Biologically Active Products of Group A Streptococci.
Gene H. Stollerman, Chicago, Prophylaxis Against Rheumatic Fever.
Currier McEwen, New York, Treatment of Rheumatic Fever and Carditis.
Robert P. Glover, Philadelphia, Surgical Treatment of Heart Conditions.

Dr. Katharine Dodge Brownell, chairman of the New York Heart Association public health committee, will deliver the opening address at the afternoon session. A panel discussion will follow.

Pediatric Fellowships.—The children's division of the Institute of Physical Medicine and Rehabilitation, New York University-Bellevue Medical Center, announces the availability of two fellowships in pediatric rehabilitation for pediatricians, made possible by funds supplied by the Association for the Aid of Crippled Children. Training will be offered in the rehabilitation of children with disabilities resulting from neuromuscular, muscular, and orthopedic conditions. The stipend is $4,000, and the training period is one year, beginning Jan. 1 or July 1, 1956. Information can be obtained by writing Dr. George G. Deaver, Director, Children's Division, Institute of Physical Medicine and Rehabilitation, New York University-Bellevue Medical Center, 400 E. 34th St., New York 16.

NORTH CAROLINA

Dr. Carter Honored.—The Carter Travel Club, a group of 48 obstetricians and gynecologists who trained at least one year under Dr. F. Bayard Carter, chairman, department of obstetrics and gynecology, Duke University School of Medicine, Durham, recently presented a portrait of Dr. Carter to the medical school. Dr. Carter, who is president of the American Board of Obstetrics and Gynecology, was awarded the Algernon Sydney Sullivan award last year for "selfless devotion to humanity . . . Countless acts of kindness and generosity to the sick, to the unfortunate and to his associates reflect the nobility of mind and heart which motivates his daily life." A member of the Duke faculty since 1931, Dr. Carter previously taught at Yale University School of Medicine, New Haven, Conn., and was head of the department of obstetrics and gynecology, University of Virginia School of Medicine, Charlottesville. The Carter Travel Club was organized in his honor in 1951 to promote further knowledge in the field of obstetrics and gynecology.

OKLAHOMA

Society News.—Dr. Stewart G. Wolf Jr., professor of medicine, University of Oklahoma School of Medicine, Oklahoma City, will be guest speaker at the dinner meeting of the Tulsa Academy of General Practice Nov. 28, 6:30 p. m. at the Hotel Tulsa, discussing "Evaluation of Gastro-Intestinal Symptoms." For reservations call LUther 2-5904. The scientific program will begin at 8 p. m. Physicians, including those who are not members of the academy, are invited. Dr. Wolf was formerly associate professor of medicine at Cornell University Medical College, New York.

Medical History Tape Recorded.—Experiences of Oklahoma's pioneer physicians are now tape recorded, through the efforts of the Oklahoma State Medical Assistants Society, which presented a recorder and a supply of tape to the department of archives of the University of Oklahoma for the recording of events of medical history. The first tape recordings were made during the annual meeting in Tulsa in May. In July, a few weeks before the death of Dr. William W. Rucks Sr., Oklahoma City, a recording of his reminiscences was made by the archives department.

Tumor Conference.—The Oklahoma division of the American Cancer Society has announced its third annual tumor conference to be held Dec. 2 at the Huckins Hotel, Oklahoma City. Visiting speakers include Drs. Luke W. Able, professor of pediatric surgery, Baylor University College of Medicine, Houston, Texas; Charles S. Cameron, medical director, American Cancer Society, New York; H. Close Hesseltine, professor of obstetrics and gynecology, University of Chicago School of Medicine; Samuel F. Marshall, surgeon, the Lahey Clinic, Boston; and David A. Wood, director of the Cancer Research Institute, University of California School of Medicine, San Francisco. The program, held in conjunction with the annual meeting of the Oklahoma division of the American Cancer Society, will feature two papers by each of the guest speakers. A clinical pathological conference will be held at 8 a. m. There will be no registration fee, but doctors are requested to register in advance by writing the Oklahoma Division, American Cancer Society, 937 Commerce Exchange Building, Oklahoma City. Reservations are needed for the noon luncheon and evening session. The program will close with the annual dinner of the Oklahoma division of the American Cancer Society at 7 p. m., to which all doctors are invited. The guest speaker will be Dr. Charles S. Cameron, New York.

PENNSYLVANIA

Rheumatic Fever Prevention Study.—A study to establish criteria for streptococcal control in the school population as a nationwide basis for community programs on rheumatic fever prevention will be conducted in three Philadelphia elementary schools by the Heart Association of Southeastern Pennsylvania in cooperation with the American Heart Association and local groups. Earlier studies in a military population demonstrated the efficacy of prompt and adequate penicillin treatment of streptococcal infections in preventing initial rheumatic fever attacks. The Philadelphia study will continue for at least one year. Director is Dr. John P. Hubbard, professor of preventive medicine at the University of Pennsylvania School of Medicine, Philadelphia, who will be assisted by Dr. David Cornfield of the department of preventive medicine and pediatrics.

Philadelphia

Hospital News.—The medical staff of the Presbyterian Hospital has subscribed $115,826 toward the institution's 4 million dollar modernization fund.——Mrs. Henry P. Brown Jr., her three sons, and three daughters have given enough money to build an entire floor in one of Presbyterian Hospital's proposed new wings. The contribution was made in memory of the late Dr. Henry P. Brown Jr., who was a surgical chief at Presbyterian Hospital from 1933 to 1947 and was elected consulting surgeon on the hospital's staff in 1947.

Society News.—*The 69th annual banquet of the Association of* Ex-Resident and Resident Physicians of the Philadelphia General Hospital will be held at the Penn Sherwood Hotel, 39th and Chestnut streets, Dec. 6. Dr. Thomas Klein will be the honored guest at the dinner, and Dr. Samuel B. Hadden, retiring president of the association, the toastmaster. Cocktails in the oyster bar (6 p. m.) will precede dinner, 7 p. m. Reservations may be procured by writing to the secretary-treasurer, Dr. John D. Corbit Jr., 3717 Chestnut St., Philadelphia 4.

Lectures on Medical Writing.—A new series of lectures on medical writing has been initiated by the Graduate School of Medicine of the University of Pennsylvania. On Nov. 10, "Medical Writing and the Physician" was presented by Dr. Jacques P. Gray, lecturer on medical writing, Parke, Davis and Company, Detroit, and on Nov. 17, "Medical Writing and the Public" by Mr. Pierre C. Fraley, medical editor, *Philadelphia Evening Bulletin.* On Dec. 1 "Medical Illustration" will be discussed by Miss Edna C. Hill, medical illustrator, Hospital of the University of Pennsylvania; "Bibliographic Research" by Miss Virginia Beatty, Library of the Philadelphia College of Physicians; and "Editorial Requirements" by Robert Rowan, managing editor, W. B. Saunders Company. "Selection of Material for Publication" will be the topic on Dec. 8 of Dr. Morris Fishbein, Chicago. "Art of Medical Writing; Use of Words" will be considered Dec. 15 by Dr. Paul R. Hawley, Chicago, director, American College of Surgeons. On Jan. 12, 1956, "Art of Readable Medical Writing" will be presented by Rudolf Flesch, Ph.D., author and educator. The meetings will be held in the Zoology Amphitheatre, 39th Street and Hamilton Walk, at 7 p. m.

Personal.—The Lebanese Republic has awarded a citation and a medal of Knight of the Order of Cedars to Dr. Hobart A. Reimann, formerly professor of medicine, Jefferson Medical College of Philadelphia, for medical services to the people of Lebanon while serving as visiting professor of medicine at the American University of Beirut since 1952.——Dr. Harry E. Bacon, head, department of proctology, Temple University School of Medicine, has been elected an honorary fellow of the Japanese College of Surgeons and the Philippine College of Surgeons. More recently he was given an honorary fellowship in the Brazilian College of Surgeons and the Turkish Surgical Society of Istanbul.——Dr. Donald L. Glenn, regional medical officer of the eastern region, Pennsylvania Railroad, has been appointed medical director, to succeed Dr. Norbert J. Roberts, who resigned. Dr. Glenn has been affiliated with the George F. Geisinger Memorial Hospital and Foss Clinic, Danville, the Mayo Clinic, Rochester, Minn., and the Carle Memorial Hospital Clinic, Urbana, Ill.——Standard Oil Company (New Jersey) has appointed as associate medical director Dr. Norbert J. Roberts, who was a member of its medical department from 1949 to 1952. For three years, Dr. Roberts has been medical director of the Pennsylvania Railroad.

RHODE ISLAND

Grant for Critical Care Unit.—The Rhode Island Hospital, Providence, has received a grant of $56,000 from the John A. Hartford Foundation for the development and evaluation of a specially designed 28-bed nursing unit in the new hospital building to be dedicated soon. This new type of unit, staffed with specially trained personnel, will meet the postoperative needs of patients who have undergone extreme surgery and will also provide more adequate care for critically ill patients.

VIRGINIA

Meeting of Oto-Ophthalmologists.—The Virginia Society of Ophthalmology and Otolaryngology will hold its annual fall [illegible] at the Baruch Auditorium, Medical College of Virginia, Nov. 29-Dec. 2. The speakers for the otolaryngology program, Tuesday and Wednesday, will be Drs. Victor Alfaro and Aram Glorig, Washington, D. C.; Lawrence R. Boies, Minneapolis; Robert J. Huebner, Bethesda, Md.; Lyle M. Sellers, Dallas, Texas; Ben H. Senturia, St. Louis; and Henry P. Wagener, Rochester, Minn. The ophthalmology program (Thursday and Friday) according to the announcement will have as speakers Drs. Howell W. Brown, James Spencer Dryden, Washington, D. C., William M. Hart, Bethesda, Md., William Howard, Edward Norton, and Henry P. Wagener.

Personal.—Dr. Ezra Goyings Jr., Richmond, has been appointed to the staff of Greenbrier Valley Hospital in Ronceverte, W. Va. ——Dr. Hubert D. Crow, health director at Fredericksburg since 1948, has been appointed director of the state health department's new medical training section. He will also, with the help of an assisting physician, carry the dual post of health director for Suffolk and the counties of Isle of Wight, Southampton, and Nansemond. His headquarters will be in Suffolk, where he succeeds Dr. William H. Michael, who has retired.

GENERAL

Meeting on Thoracic Surgery.—The second annual meeting of the Southern Thoracic Surgical Association will be held at the Greenbrier, White Sulphur Springs, W. Va., Dec. 2-5. The guest speaker, Dr. C. Walton Lillehei, University of Minnesota Medical School, Minneapolis, will discuss "Experiences with Open Cardiac Procedures for Various Congenital Conditions."

Grants in Cerebral Palsy.—United Cerebral Palsy, 369 Lexington Ave., New York 17, has approved 46 grants totaling $395,000 as the spring series of its 1955-1956 research and training program, of which 23 are for medical research. The remainder will be used to train professional personnel to make treatment and other care available to more of the cerebral palsied. Included are fellowship and scholarship programs for physicians, physical and occupational therapists, teachers, dentists, vocational guidance counselors, and pediatric neurologists. Other training grants support summer workshops or year-round training programs at hospitals and universities.

Safe Driving Day.—The President's Committee for Traffic Safety is sponsoring a special day dedicated to safe driving, S-D Day, Dec. 1, in an attempt to hold deaths and injuries to the lowest possible level for a 24-hour period. The National Safety Council points out that "while perfection probably is too much to expect—even for one day—from a combination of about 72 million drivers and 58 million motor vehicles, no sensible person would argue for a minute that the usual toll cannot be substantially cut by more sensible driving." It is hoped that the S-D Day record this year will show an improvement over the 15% reduction in deaths achieved on S-D Day last year.

Hematologists Meet in Boston.—The International Society of Hematology will hold its sixth congress at the Hotel Somerset in Boston, Aug. 27-Sept. 1, 1956, under the presidency of Dr. William Dameshek of that city. Themes of the session will include immunohematology (Monday); nucleonics in hematology (Tuesday); leukemia and related states (Thursday); anemia (Friday); and hemorrhagic disorders (Saturday). An all-day excursion on the ocean-going Boston Belle to Provincetown at the tip of Cape Cod, a New England clambake, and moonlight dancing are planned for Wednesday. Communications should be addressed to the International Society of Hematology, New England Medical Center, Harrison Avenue at Bennet Street, Boston 11.

Southern Surgical Association.—The 67th annual session of the Southern Surgical Association will convene at the Homestead Hotel, Hot Springs, Va., Dec. 6-8 under the presidency of Dr. Carrington Williams, Richmond, Va. The presidential address Tuesday, 9:30 a. m., will be followed by "The Treatment of Mass Casualties in Disaster" by Dr. Frank B. Berry, Washington, D. C. The 44 presentations scheduled include participation by 26 invited speakers. The association cocktail party Wednesday, 6:30 p. m., will precede the dinner at which Dr. John M. T. Finney Jr., Baltimore, will serve as toastmaster. The guest speaker, Sir Yevrah Enots, M.D., H.K.R.S., of Addis Ababa, Abyssinia, will discuss "Some Experiences of a Surgeon at a Royal Court."

Typhoid Infection.—According to the U. S. Public Health Service, the California Department of Public Health reported typhoid infection in a 70-year-old woman who had a hip abscess from which a culture revealed Salmonella typhosa, phage type C. The patient had had typhoid fever at the age of 12. The abscess was discovered 58 years later, 3 years after an open reduction and nailing for fracture of the right femur following an automobile accident. An infection was reported also in a 46-year-old woman who had an abscess at the site of a cholecystectomy scar. Salmonella typhosa, phage type 26, was isolated from this abscess. The patient stated that she had never had typhoid fever. She had spent 14 years in Mexico and had made numerous return visits.

Certification of Psychiatrists.—At the October meeting of the American Board of Psychiatry and Neurology, the following regulations were adopted: 1. *All applicants who wish to qualify* for examination for certification in psychiatry or neurology under the regulations relating to training credit and who began training on or after July 1, 1956, must show that at least 24 months of their residency training have been secured in residency training programs approved for at least two years of residency training in the specialty in which they seek certification. 2. Because of an increase of all expenses in conducting the examination, the following fee schedule will be in effect as of Jan. 1, 1956: application fee, $50; examination fee, $75; complete reexamination fee, $75; partial reexamination fee, $50.

Meeting on Clinical Research.—The eastern section of the American Federation for Clinical Research will hold its annual meeting Dec. 2-3 at the College of Physicians Building (19 S. 22nd St., Philadelphia). During the opening session Friday morning "Peripheral Venous Responses to Body Cooling and Warming in Man" will be presented by Drs. J. Edwin Wood and John W. Eckstein, Boston (by invitation), and "Hemodynamic Effects of the Hufnagel Valve" by Drs. Joseph Roshe and J. Alexander Haller Jr., Bethesda, Md. (by invitation). The 37 presentations will include participation by 53 invited speakers. The National Drug Company, Philadelphia, will be host at luncheon on Friday. The social hour, courtesy of Smith, Kline and French, will precede the dinner Friday, at which Wyeth Laboratories will be host.

Chest Physicians Meet in Boston.—The interim session of the American College of Chest Physicians will be held at the Sheraton-Plaza Hotel, Boston, Nov. 27-28. A scientific program, sponsored by the New England states chapter of the college, will include panel discussions, "The Short-of-Breath Patient" and "Hemoptysis," and a diagnostic-treatment conference. Round-table luncheon discussions are scheduled on cor pulmonale and on antimicrobial agents. At the cocktail party and dinner Dr. James H. Stygall, Indianapolis, president, American College of Chest Physicians, will be the guest of honor. Fireside conferences are planned on emphysema, tumors of the lung, coronary disease, immunity and vaccination in tuberculosis, angiocardiography, and advances in cardiac surgery. All physicians are cordially invited to attend the scientific sessions; there is no registration fee.

Conference on Public Welfare.—The 25th anniversary of the American Public Welfare Association will be celebrated at the biennial round-table conference, Nov. 30-Dec. 3, in the Hotel Statler, Washington, D. C. The opening session Wednesday morning will be addressed by Charles I. Schottland, commissioner of social security, Social Security Administration, Department of Health, Education, and Welfare, Washington, D. C. The round-table discussions will include: Public Welfare Services for Older People; (1) Improving the Quality of Tax-Supported Medical Care and (2) Public Child Welfare Services—Past and Future (Thursday morning); (1) Purposeful Living Through Rehabilitation and (2) What Should the Welfare Department Expect from the Health Department? (Friday morning); Mental Health and the Community (Friday afternoon); and Standards Help in Care of the Chronically Ill (Saturday morning).

Meeting on Hypnosis.—The Society for Clinical and Experimental Hypnosis will hold its sixth annual scientific meeting at the New York Academy of Sciences (2 E. 63rd St., New York City) Dec. 3. Remarks by the president, Dr. Jerome M. Schneck, New York City, will precede a program reported here in part:

Use of Hypnosis in Evaluating the Physiological and Psychological Components in the Functional Impairment of the Patient with Multiple Sclerosis, Arthur Shapiro, Brooklyn, and Milton V. Kline, Ed.D. Long Island University, Brooklyn.
Control of the Dumping Syndrome by Hypnosis, Roy M. Dorcus, Ph.D., Los Angeles, and Philip Goodwin, Ph.D., Sawtelle Center, Veterans Administration, Los Angeles.
Hypnosis and the Dissociative Reactions, Louis Jolyon West, University of Oklahoma School of Medicine, Oklahoma City.

Request for dinner reservations (Barbizon Plaza Hotel, Dec. 3, 7 p. m., $7 per person) should be sent with check to J. Stolzenberg, D.D.S., 1 Nevins St., Brooklyn 17.

Symposium on Geriatric Medicine.—A graduate symposium on geriatric medicine will be presented by the American Geriatrics Society Nov. 30-Dec. 1 at the Hotel Roosevelt, New York City. A panel on heart disease Wednesday, 3:45 p. m., will have as moderator Dr. Charles T. Stone Sr., Galveston, Texas, and as participants Drs. David Lehr, Harold E. B. Pardee, Harry Gold, and Robert L. Levy, New York City, and Dr. Wesley E. Peltzer, Salt Lake City. Dr. Walter Bauer, Boston, will moderate a panel on rheumatic diseases Thursday, 2 p. m., at which the participants will be Drs. Russell L. Cecil, Richard H. Freyberg, and Charles A. Ragan, New York City, and Dr. Joseph Lee Hollander, Philadelphia. The sessions will close with a panel on some psychological and psychiatric problems of old age, Thursday, 4:30 p. m. Dr. Edward B. Allen, White Plains, N. Y., will serve as moderator. Dr. Hollis E. Clow, White Plains, N. Y., Dr. David C. Wilson, Charlottesville, Va., and Mr. Clark Tibbitts, chairman, Committee on Aging, Department of Health, Education, and Welfare, Washington, D. C., will be collaborators. Dr. Edward E. Henderson, Montclair, N. J., is president of the society.

Surgeons Meet in Seattle.—The Western Surgical Association will hold its 63rd annual meeting at the Olympic Hotel, Seattle, Dec. 1-3. A premeeting clinic day is scheduled for Nov. 30. Operative clinics will be held at the Virginia Mason Hospital and the Swedish Hospital Wednesday morning. At 1 p. m. buses will leave the Olympic Hotel for the University of Washington School of Medicine, where Dr. Fred T. Kolouch, Twin Falls, Idaho, will serve as moderator for the program at 1:30 p. m. and Dr. Lyon H. Appleby, Vancouver, B. C., as moderator for the program at 2:50 p. m. The local arrangements committee will be host at a cocktail party at the Rainier Club, 6-7:30 p. m. The sessions will open Monday at 8:30 p. m. with "The Treatment of Carcinoma of the Hypopharynx and the Cervical Esophagus" by Dr. Orville F. Grimes, San Francisco (by invitation), after which an invitational address, "Carcinoma of the Esophagus," will be presented by Drs. Gerald S. Wilson and Joel E. Powers, Detroit. In all, the 37 presentations will include participation by 49 other speakers. The presidential address, "Doctor of Both Medicines," will be given by Dr. Michael L. Mason, Chicago, Friday morning. Cocktails Friday, 6:30 p. m., will precede the banquet at 7 p. m. Thursday afternoon is reserved for a cruise on Elliott Bay and Lake Washington. Dinner at the Seattle Yacht Club, 5 p. m., will be followed by a performance at the University of Washington Penthouse Theatre, 8 p. m.

Health Education Meeting.—The New England Health Education Association will present a fall meeting and luncheon testimonial Dec. 2, in Boston, in honor of Ira V. Hiscock, M.P.H., New Haven, Conn., president, American Public Health Association. The morning will be devoted to (1) a tour of the scientific and technical exhibits of the American Medical Association in connection with its clinical session and (2) a special showing of two health education films. At the testimonial luncheon in the Sheraton-Plaza Hotel (advance reservation requested), greetings will be extended by Dr. Elmer Hess, Erie, Pa., President, American Medical Association, before an address, "Health Education and Medical Research" by John E. Fogarty, M.C., Representative from the second Rhode Island District, and chairman, House subcommittee on appropriations, health, welfare, and education. At a meeting open to members and guests, 3 p. m., Dr. Charles C. Wilson, professor of education and public health, Yale University School of Medicine, New Haven, Conn., will serve as moderator for a panel-forum, "Consolidating for School Health Services," in which Drs. John E. Farley, school physician, East Providence, R. I., and Edward W. Colby, health director, Department of Health, Portland, Maine, will participate. Dr. Donald A. Dukelow, Chicago, consultant in health and fitness, Bureau of Health Education, American Medical Association, will be the summarizer. The Desitin Chemical Company of Providence, R. I., will be host at a reception and cocktail hour, 5:30 p. m.

Society News.—The **Tri-State Medical Association of the Carolinas and Virginia** invites participation in the program of its 59th annual meeting at Charlotte, N. C., Feb. 20-21, 1956. Titles of papers should be sent to Dr. Roy B. McKnight, Professional Building, Charlotte, N. C.——At its 60th annual convention in Los Angeles, the **National Medical Association** presented its Distinguished Service award medal to Dr. W. Montague Cobb, Washington, D. C., for scientific endeavors in medical and other fields and the award for the General Practitioner of the Year to Dr. W. Burlin Humphrey of Los Angeles. Certificates and gold medals were awarded to about 200 physicians who had been practicing 40 years or more. The following officers were elected: Dr. August C. Terrence, Opelousas, La., president; Dr. Theodore R. M. Howard, Mound Bayou, Miss., president-elect; Drs. Vaughan C. Mason, New York, James S. Smith, Muncie, Ind., and Elias B. Thompson, Williamson, W. Va., vice-presidents; Dr. John T. Givens, Norfolk, Va., executive secretary; and Dr. Eugene T. Taylor, St. Louis, treasurer. The 1956 convention will be held in New York City.——The **National Multiple Sclerosis Society** has appointed as director of the medical and scientific department, Frederick L. Stone, Ph.D., assistant for professional services to the vice-chancellor, School of the Health Professions, University of Pittsburgh, and a member of the executive committee of the medical advisory board of the society. Dr. Stone's primary responsibility will be to develop expanded research and medical programs.

Meeting on Dermatology and Syphilology.—The American Academy of Dermatology and Syphilology will hold its 14th annual meeting Dec. 3-8 at the Palmer House, Chicago, under the presidency of Dr. Arthur C. Curtis, Ann Arbor, Mich. Special courses will be presented Saturday and Sunday on histopathology; mycology; x-ray and radium therapy; bacteriology and virology of the skin; application of research methods to dermatology; anatomy and embryology; special problems in dermatohistopathology. Noon informal discussion groups have been scheduled daily Sunday through Wednesday and afternoon informal discussion groups for Monday and Tuesday. The following round-table panels will be presented: Eczematous Eruptions of the Hands; Techniques in the Application of X-Ray and Radium; Common Dermatoses; Light-Sensitive Dermatoses and Porphyria; Medical Writing; Dermatologic Photography; Military Dermatology; Eczema of Infants and Children; Techniques in the Application of X-Ray and Radium; and Cutaneous Testing. The sessions will open Monday at 10:30 a. m. with special lectures on endocrinology in relation to dermatology (Dr. Francis E. Senear, Chicago, director). On Tuesday a special lecture, "Cause and Effect in Relation to Disease," will be presented at 8:30 p. m. by Dr. William Boyd, Toronto, Canada. Tuesday afternoon Dr. George C. Andrews, New York, will serve as chairman for a panel on the diagnosis and treatment of cutaneous malignancy, with Dr. John R. Freid, chief of the radioisotope service at Montefiore Hospital and Bronx Hospital, New York, as guest. An all-day clinical pathological conference is scheduled for Wednesday. The 16 symposiums will include an all-day symposium on pharmaceutical therapeutics Thursday. The first presentation at the symposium on cutaneous granulomas Tuesday morning will be "Tuberculosis of the Skin," the first John E. Rauschkolb Memorial Lecture, by Dr. J. J. Zoon, professor of dermatology, University of Utrecht, Holland. Cocktails at 6:30 p. m. will precede the annual banquet and entertainment Wednesday (formal dress optional). The next two annual meetings of the academy will be held Dec. 8-13, 1956, and Dec. 7-12, 1957, at the Palmer House.

Easter Seal Convention.—The annual convention of the National Society for Crippled Children and Adults will convene at the Palmer House, Chicago, Nov. 28-30. Dr. Leonard A. Scheele, surgeon general, U. S. Public Health Service, Washington, D. C., will be among the speakers at the opening session Monday, 9:30 a. m. At 11:30 a. m. the exposition on employment of the physically handicapped will have its grand opening. This exposition will feature on-the-job demonstrations of disabled employees. More than 75 firms located in various industrial areas of the United States will be among the exhibitors participating in this free exhibit, which will be sponsored by the society, the President's Committee on Employment of the Handicapped, and the Illinois Governor's Committee on Employment of the Physically Handicapped. Dr. Clinton L.

Compere and associates, Chicago, will participate in the seminar for physicians, physical therapists, and occupational therapists (Monday afternoon), "Techniques in Amputee Training," which will include a clinic demonstration of patients. The theme of the convention, "Conquering Crippling," will be elaborated in the presentation Tuesday, 9:30 a. m., of "The Role of the General Practitioner in Conquering Crippling" by Dr. John R. Fowler, Barre, Mass., president, American Academy of General Practice. Tuesday afternoon seminars will deal with speech rehabilitation and the social and emotional adjustment of the teenage crippled child. The Wednesday morning session will be opened at 9:30 a. m. with presentation of "New Resources for Conquering Crippling" by Mary Switzer, director, U. S. Office of Vocational Rehabilitation, Department of Health, Education, and Welfare, Washington, D. C., which will be followed by "Conquering Crippling As I See It" by Dr. Harold B. Boyd, associate professor of orthopedic surgery, University of Tennessee College of Medicine, Memphis, Tenn., and past-president, American Academy of Orthopaedic Surgeons. "The Compleat Person" by Dr. Francis J. Braceland, Hartford, Conn., president-elect, American Psychiatric Association, will precede discussion of "Conquering Crippling—Whose Responsibility?" for which Mr. Lawrence Spivak, Washington, D. C., and New York, producer of the television program, "Meet the Press," will serve as chairman.

CORRECTION

Cooley's Trait.—Throughout the letter from Israel entitled "Cooley's Anemia in Oriental Jews" in The Journal, Sept. 24, 1955, page 395, the words "Cooley's trait" should be substituted for "Cooley's anemia." Cooley's trait was described by Dreyfuss; its characteristics are given in the letter but are erroneously ascribed to Cooley's anemia.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

1956 Annual Meeting, Chicago, June 11-15.

1956 Clinical Meeting, Seattle, Nov. 27-30.

1957 Annual Meeting, New York, June 3-7.

1957 Clinical Meeting, Philadelphia, Dec. 3-6.

National Medical Public Relations Conference, Hotel Statler, Boston, Nov. 28. Mr. Leo F. Brown, 535 N. Dearborn St., Chicago 10, Director.

American Academy of Dermatology and Syphilology, Palmer House, Chicago, Dec. 3-8. Dr. James R. Webster, 55 East Washington St., Chicago 2, Secretary.

American Academy of Obstetrics and Gynecology, Conrad Hilton Hotel, Chicago, Dec. 13. Dr. C. Paul Hodgkinson, 116 South Michigan Blvd., Chicago, Secretary.

American League Against Epilepsy, Roosevelt Hotel, New York, Dec. 8. Dr. Peter Kellaway, Baylor University College of Medicine, Houston 25, Tex., Secretary.

American Rheumatism Association, Interim Session, National Institutes of Health, Bethesda, Md., Dec. 9. Dr. Edward F. Hartung, 580 Park Ave., New York 21, Secretary.

Association for Research in Nervous and Mental Diseases, Hotel Roosevelt, New York, Dec. 9-10. Dr. Clarence C. Hare, 710 West 168th St., New York 32, Secretary.

Eastern Section, American Federation for Clinical Research, Hotel Warwick and College of Physician's Building, Philadelphia, Dec. 2-3. Dr. Charles R. Shuman, Temple Univ. Hospital, Broad and Ontario Sts., Philadelphia 40, Chairman.

Eastern Section, American Laryngological, Rhinological and Otological Society, Boston, Jan. 13. Dr. John A. Murtagh, Dartmouth College, Hanover, N. H., Vice President.

Los Angeles Midwinter Medical Convention, Biltmore Hotel, Los Angeles, Jan. 3-5. Dr. Paul D. Foster, 1925 Wilshire Blvd., Los Angeles 58, General Chairman.

Middle Section, American Laryngological, Rhinological and Otological Society, Netherland Plaza, Cincinnati, Jan. 16. Dr. William H. Craddock, 2328 Auburn Ave., Cincinnati 19, Vice President.

Medical Society Executives Conference, Parker House, Boston, Nov. 27. Mr. H. Martin Baker, 1102 South Hillside, Witchita 17, Kansas, Secretary.

New England Health Education Association, Boston, Dec. 2. Miss Wyntha Tompkins, Middlesex Health Association, Essex, Mass., Secretary.

Puerto Rico Medical Association, Santurce, Dec. 7-11. Dr. Luis R. Guzman-Lopez, Box 9111, Santurce, Secretary.

Radiological Society of North America, Palmer House, Chicago, Dec. 11-16. Dr. Donald S. Childs, 713 E. Genesee St., Syracuse 2, N. Y., Secretary.

Regional Meetings, American College of Physicians:

- Detroit, Dec. 3. Dr. H. Marvin Pollard, 1313 East Ann St., Ann Arbor, Mich., Governor.
- Hot Springs, Ark., Dec. 3. Dr. A. A. Blair, 100 S. 14th St., Ft. Smith, Ark., Governor.
- Winston-Salem, N. C., Dec. 8. Dr. Elbert Persons, Duke Hospital, Durham, N. C., Governor.
- Shreveport, La., Jan. 14, Dr. M. D. Hargrove, 803 Jordan St., Shreveport, La., Governor.
- Philadelphia, Jan. 20. Dr. Thomas M. McMillan, 330 South 9th St., Philadelphia 7, Governor.

Sectional Meetings, American College of Surgeons:

- Jacksonville, Fla., Hotel George Washington, Jan. 16-18. Dr. Kenneth A. Morris, 2522 Oak St., Jacksonville 4, Fla., Chairman.

Southern Section, American Federation for Clinical Research, Jung Hotel, New Orleans, Jan. 20. Dr. John H. Moyer, 1200 M.D. Anderson Blvd., Houston, Tex., Secretary.

Southern Surgical Association, The Homestead, Hot Springs, Va., Dec. 6-8. Dr. George G. Finney, 2947 St. Paul St., Baltimore 18, Secretary.

Southern Thoracic Surgical Association, The Greenbrier, White Sulphur Springs, W. Va., Dec. 2-5. Dr. Hawley H. Seiler, 442 West Lafayette St., Tampa 6, Fla.

Western Section, American Laryngological, Rhinological and Otological Society, County Medical Society Bldg., San Francisco, Jan. 21. Dr. David D. DeWeese, 1216 S. W. Yamhill St., Portland, Ore., Vice President.

Western Surgical Association, Olympic Hotel, Seattle, Dec. 1-3. Dr. John T. Reynolds, 612 N. Michigan Blvd., Chicago 11, Secretary.

FOREIGN AND INTERNATIONAL

All India Medical Conference, Jaipur, India, Dec. 26-28. Dr. B. N. Consul, Association Bldg., S.M.S. Hospital Premises, Jaipur, India, Organizing Secretary.

Canadian Medical Association, Quebec, P. Q., Canada, June 10-14, 1956. Dr. Arthur D. Kelly, 150 St. George St., Toronto 5, Ont., Canada, Secretary.

Conference of International Union for Health Education of the Public, Rome, Italy, Apr. 27-May 5, 1956. Mr. Lucien Viborel, 92 rue St. Denis, Paris 1er, France, Secretary-General.

Congress of International Anesthesia Research Society, Miami Beach, Fla., U.S.A., April 9-12, 1956. For information write: Dr. R. J. Whitacre, 13951 Terrace Road, Cleveland 12, Ohio, U. S. A.

Congress of International Association of Limnology, Helsinki, Finland, July 26-Aug. 7, 1956. For information address: Dr. H. Luther, Snellmansgatan 16 C 36, Helsinki, Finland.

Congress of International Association of Logopedics and Phoniatrics, Barcelona, Spain, Sept. 3-7, 1956. Dr. J. Perello, Provenza 319, Barcelona 9, Spain, Secretary-General.

Congress of International Society of Hematology, Hotel Somerset, Boston, Mass., U.S.A., Aug. 27-Sept. 1, 1956. Dr. W. C. Moloney, 39 Bay State Road, Boston, Mass., U.S.A., Secretary.

Congress of Latin Society of Ophthalmology, Madrid, Spain, April 24-28, 1956. For information address: Dr. Costi, Montalban 3, Madrid, Spain.

European Congress of Allergology, Florence, Italy, Sept. 12-15, 1956. Prof. Umberto Serafini, Instituto de Patologia Medica, Viale Morgagni, Florence, Italy, Secretary-General.

European Congress of Cardiology, Stockholm, Sweden, Sept. 10-14, 1956. Dr. Karl Erik Grewin, Sodersjukhuset, Stockholm, Sweden, General Secretary.

European Symposium on Vitamin B_{12}, Hamburg, Germany, May 1956. For information write: Doz. Dr. H. Bauer, Nervenklinik, Hamburg-Eppendorf, Germany.

Inter-American Congress of Cardiology, Havana, Cuba, Nov. 4-10, 1956. For information address: Dr. Ramon Aixala, Apartado 2108, Havana, Cuba.

International Academy of Pathology, Cincinnati, Ohio, U. S. A., April 24-25, 1956. Dr. F. K. Mostofi, Armed Forces Institute of Pathology, Washington 25, D. C., U. S. A., Secretary.

International Congress Against Alcoholism, Istanbul, Turkey, Sept. 10-15, 1956. For information address: International contre l'Alcoolisme, Case Gare 49, Lausanne, Switzerland.

International Congress of Anthropological and Ethnological Sciences, Philadelphia, Pa., U. S. A., Sept. 2-9, 1956. Dr. William N. Fenton, National Research Council, Division of Anthropology and Psychology, 2101 Constitution Avenue, Washington 25, D. C., U. S. A., Secretary-General.

International Congress of Blood Transfusion, Boston, Mass., U. S. A., Aug. 29-Sept. 2, 1956. Dr. J. Julliard, 57, Boulevard L'Auteuil, Boulonge-sur-Seine, France, Secretary General.

International Congress on Diseases of the Chest, Cologne, Germany, Aug. 19-23, 1956. Mr. Murray Kornfeld, 112 East Chestnut St., Chicago 11, Illinois, U. S. A., Executive Director.

International Congress of Entomology, Montreal, Canada, Aug. 17-25, 1956. Mr. J. A. Downes, Science Service Bldg., Carling Ave., Ottawa, Ont., Canada, Secretary.

International Genetics Symposium, Tokyo and Kyoto, Japan, Sept. 6-12, 1956. For information address: Secretary, International Genetics Symposium, Science Council of Japan, Ueno Park, Tokyo, Japan.

International Physiological Congress, Brussels, Belgium, July 29-Aug. 5, 1956. For information address: Prof. J. Reuse, Faculte de Medicine et de Pharmacie, 115 Boulevard de Waterloo, Brussels, Belgium.

International Professional Union of Gynecologists and Obstetricians, Madrid, Spain, Sept. 28-29, 1956. Dr. Jacques Courtois, 1 rue Racine, St-Germain-en-Laye (S and O), France, Permanent International Secretary-General.

Latin American Congress of Pathology, Mexico, D. F., Mexico, Dec. 11-17. For information address: Laboratorio de Anatomia Patologica, Instituto N. de Cardiologia, Avenida Cuauhtemoc 300, Mexico 7, D. F., Mexico.

Latin American Congress of Physical Medicine, San Juan, Puerto Rico and Curacao, N.W.I., Jan. 29-Feb. 8, 1956. Dr. Cassius Lopez de Victoria, 176 East 71st St., New York 21, New York, U. S. A., Executive Director.

Medical Women's International Association, Extraordinary General Assembly, Burgenstock, Nidwalden, Switzerland, Sept. 21-23, 1956. Dr. Janet Aitken, 30a Acacia Road, London N.W. 1, England, Secretary.

North Queensland Medical Conference, Cairns, North Queensland, Australia, June 25-30, 1956. Dr. W. R. Horsfall, P.O Box 672, Cairns, N.Q., Australia, Secretary.

Pan-American Academy of General Practice, San Juan, Puerto Rico and Curacao, N.W.I., Jan. 29-Feb. 8, 1956. Dr. Arturo Martinez, 54 East 72d St., New York 21, New York, U. S. A., Secretary.

Pan American Congress of Gastroenterology, Havana, Cuba, Jan. 20-27, 1956. For information address: Dr. Norberto M. Stapler, 1267 J. E. Uriburu, Buenos Aires, Argentine, S. A.

Pan American Congress of Ophthalmology, Santiago, Chile, S. A., Jan. 9-14, 1956. Dr. Rene Contardo, Huerfanos 930, Of. 74, Santiago, Chile, Secretary General.

Pan American Congress of Otorhinolaryngology and Bronchoesophagology, San Juan, Puerto Rico, April 8-12, 1956. Dr. C. E. Munoz MacCormick, Apartado 9111, Santurce 29, Puerto Rico, Secretary General.

Pan American Medical Women's Alliance, Santiago, Chile, March 6-13, 1956. For information address: Dr. Eva Cutright, 458 Beall Ave., Wooster, Ohio, U. S. A.

World Congress on Fertility and Sterility, Naples, Italy, May 18-26, 1956. For information address: Prof. G. Tesauro, S. Andrea della Dame, 19, Naples, Italy.

World Medical Association, Havana, Cuba, Oct. 9-15, 1956. Dr. Louis H. Bauer, 345 East 46th St., New York 17, New York, U. S. A., Secretary-General.

EXAMINATIONS AND LICENSURE

EXAMINING BOARDS IN SPECIALTIES

American Board of Dermatology and Syphilology. *Written.* Various centers, July 26. *Oral.* St. Louis, Oct. 12-15. Sec., Dr. B. M. Kesten, One Haven Ave, New York 32.

American Board of Internal Medicine: *Oral.* Chicago, Nov. 30-Dec. 1. *Subspecialties. Cardiovascular Disease.* Chicago, Nov. 30. The closing date for acceptance of application for gastroenterology was Feb. 1, and for cardiovascular disease the closing date was June 1. *Written.* Oct. 15, 1956. Final date for filing application is May 1. *Oral Examinations in 1956.* New Orleans, Feb. 7-10; Los Angeles, April 12-14; Chicago, June 7-9. Final date for filing application for these three oral examinations is Jan. 3. New York City, Sept. 21-25. Final date for filing application is April 1. Exec. Sec., Dr. William A. Werrell, 1 West Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* New Haven, November. Oral examinations given in Spring and Fall. Final date for filing application for the Spring examination was October 1; for the Fall examination April 1. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

American Board of Obstetrics and Gynecology: *Written Examination and submission of Case Reports. Part I.* Various locations in United States and Canada, and military centers outside of the Continental United States, Feb 3, 1956. Final date for filing application was Oct. 1. *Oral and Pathological Examinations. Part II.* Chicago, May 11-20, 1956 Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Written.* January 24-26, 1956. *Practical Examination.* San Francisco, June 18-21, St. Louis, Oct. 20-25. Applications for 1957 written examination must be filed before July 1. 1956. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland 9, Maine.

American Board of Orthopaedic Surgery: *Oral.* Jan. 26-27. Final date for filing application was Aug. 15. *Part I. Oral and written.* Various centers, April 1956. Final date for filing application is Nov. 30. Sec., Dr. Harold A. Sofield, 116 South Michigan Ave., Chicago 3.

American Board of Otolaryngology. *Oral.* Montreal, Canada, May 6-10. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pediatrics: *Oral.* Washington, D. C., Dec 2-4 Admin. Sec., Mrs. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Physical Medicine and Rehabilitation. *Parts I and II.* Chicago, June 16-17. Sec., Dr. Earl C. Elkins, 200 First St., S. W., Rochester, Minn.

American Board of Plastic Surgery. *Entire Examination.* Buffalo, May 13-15. Final date for filing case reports is Jan. 1. Corres. Sec., Mrs. Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8.

American Board of Preventive Medicine: *Certification in Public Health.* Kansas City, Mo., Nov. 10-12. Sec.-Treas., Dr. Ernest L. Stebbins, 615 N. Wolfe St., Baltimore 5.

American Board of Psychiatry and Neurology: New York City, December, Philadelphia, April 16-18, 1956. Sec., Dr. David A. Boyd, 102-110 Second Ave. S.W., Rochester, Minn.

American Board of Radiology: Chicago, Dec. 4. Final date for filing applications for the fall examination was July 1. Candidates who will complete their training by Dec. 31 will be eligible to appear for this examination. Deadline for filing applications for the Spring 1956 examination is Jan. 1. Those candidates who will complete their training by June 30, will be eligible to appear at this examination. Sec., Dr. B. R. Kirklin, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Part I.* Centers throughout the United States, in Europe and in the Far East, March 28. Closing date for the March examination is December 1. *Part II.* New York City, Nov. 14-15; St. Louis, Dec. 12-13; New Orleans, Jan. 16-17; Los Angeles, Feb. 13-14; San Francisco, Feb. 16-17; Durham, March 12-13; Boston, May 14-15 and Philadelphia, June 4-5. Sec., Dr. John B. Flick, 255 S. Fifteenth St., Philadelphia 2.

Board of Thoracic Surgery. *Written.* February 1956. Closing date for filing application is Dec. 1. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2, Mich.

MAGAZINE-TELEVISION REPORT

The following list of current medical articles in mass-circulation magazines and forthcoming network television programs on medical subjects is published each week only for the information of readers of THE JOURNAL. *Unless specifically stated, the American Medical Association neither approves nor disapproves of the articles and programs reported.*

TELEVISION

Sunday, Dec. 4

NBC-TV, 10:30 p. m. EST. "March of Medicine," produced in cooperation with the American Medical Association, presents "Alcoholism—the Revolving Door," featuring case histories of alcoholics and remarks by Marvin A. Block, chairman of the A. M. A. Committee on Alcoholism.

Monday, Dec. 5

NBC-TV, 11 a. m. to 12 noon EST. "Medical and Health News with Howard Whitman," a segment of the "Home" show.

NBC-TV, 9 p. m. EST. "Medic," in a drama titled "Pray Judgment," shows how a post mortem after the death of a child proves that the death was accidental and not the result of negligence by the child's aunt.

ABC-TV, 9:30 p. m. EST. "Medical Horizons" visits Duke University School of Medicine, Durham, N. C., to report on work done so far with the problem of headache. Produced in cooperation with the American Medical Association.

MAGAZINES

Look, Nov. 29, 1955

"He Lost 125 Pounds in 7 Months," by Peter Van Slingerland

A family doctor helps a 21-year-old farm boy back to good health through a controlled, low-calorie diet. He once weighed 297 lb.

Look, Dec. 13, 1955

"War Among the Doctors," by Roland H. Berg

Covering what it terms the fight over fees between general practitioners and specialists, this article states that most general practitioners feel their prestige has been threatened by the dramatic, highly paid surgeon . . . that they have been frozen out of the operating room by hospitals that restrict surgery to board-certified specialists . . . that their share of the medical dollar is inequitable compared to the share of specialists. The article discusses the A. M. A.-sponsored Truman committee report in relation to these charges and adds psychologist Ernest Dichter's view that the battle is one of the physician's "inner conflict" between being a humanitarian and making a living.

Redbook, December, 1955

"The Healing of Sharon Webb," by Le Nell Webb

A mother tells of her small daughter's deformity (a congenital hip dislocation), of its eventual correction by orthopedic skill and patience, and of the return of her faith after the birth of another, normal child.

"How Dangerous Is TB Now?" by Alton L. Blakeslee

The public may be underestimating the prevalence of tuberculosis despite its decline as a leading cause of death, the author warns. He advises frequent medical checkups to discover early symptoms.

Woman's Home Companion, December, 1955

"Coming: A Long-Lasting Polio Vaccine," by J. D. Ratcliff

This report describes work being done to provide long-lasting protection against poliomyelitis by doctors in three research laboratories (New York, Ohio, and Alabama). It cites the advantages of a live virus vaccine over the comparatively short-term protection of the Salk vaccine. However, the new-type vaccine is still experimental; full-scale field tests are at least two years away.

Coronet, December, 1955

"A Brother's Gift of Life," by Al Hirshberg

A report of a successful kidney transplant on identical twins.

"Your Doctor Can Add 20 Years to Your Life," by Lawrence Galton

A new medical theory claims that old age and disease need not go hand in hand: A doctor advises how to educate your body to good health and additional years of pleasant living by taking care of six major areas.

Ladies' Home Journal, December, 1955

"What They've Been Learning About Breast Feeding," by Ruth and Edward Brecher

A summary of eight years of patient research on infant nursing provides some interesting answers to why some mothers can't nurse their babies. This surgeon and psychologist (a husband and wife team) compare the lactation cycle of women to that of cows; they offer advice on feeding and nipple care.

"Tell Me Doctor," by Henry B. Safford, M.D.

Dr. Safford discusses stress incontinence or weak bladder control, a complaint from which about 5.5% of all women suffer, he says.

Better Homes and Gardens, December, 1955

"New: A 'Harmless' Germ Killer!" by Donald G. Cooley

When dissolved in water, a new drug named Chlorpactin emits vapors that annihilate viruses, bacteria, fungi, spores and yeast—yet it is so harmless, the author says, that "you could drink it or take a bath in it."

Reader's Digest, December, 1955

"Fastest Man on Earth"

This condensation of a *Time* magazine (Sept. 12) article deals with the experiments of Dr. John Paul Stapp, who was his own guinea pig in determining the effects of speed and stress on the human body.

"How I Conquered Claustrophobia," by Ben Funk

A victim of what is termed the "most common of all phobias" relates how he overcame his fear of crowded and closed-in places. Condensed from the Denver *Post* (Oct. 30).

"They Learn to Survive—the Hard Way," by John G. Hubbell

The author recounts the tough nine days of survival training he underwent, along with 23 air crews, at Stead Air Force Base, Nevada.

"Exciting Promise of the Enzyme," by Harland Manchester

Condensed from *Journal of Lifetime Living* (Dec.), the article tells of research in the enzyme field that holds forth bright promise of aid in controlling malignant growth.

"Super-Aspirins Against Arthritis," by Paul de Kruif

New help for chronic arthritis and rheumatic disease sufferers is offered in reports of a new aspirin-hormone compound. Condensed from *Today's Health* (Dec.).

"The Miracle of Lourdes," by Ruth Cranston

The author of this recently published book reports some case histories of "the cures of Lourdes." (Excerpts from the book appeared in *McCall's* November issue, reported in this column Oct. 29.)

Collier's, Nov. 25, 1955

"The Manikin That 'Breathes' and 'Bleeds,'" by Edward W. Bird, M.D.

A color picture accompanies this feature about the 6-foot, 145-pound synthetic man used as a unique teaching aid for the armed forces. The first of 19 models planned, it took 18 months to build.

Saturday Evening Post, Nov. 19, 1955

"He Gave His Kidney to His Brother," by Virginia S. Herrick

A successful kidney transplant performed one year ago is a "medical first." This is a dramatic story of the 24-year-old Herrick twins, Ronald and Richard. Ronald gave a kidney to save his brother, a victim of nephritis.

GOVERNMENT SERVICES

AIR FORCE

Symposium on Civil Defense.—More than 60 teaching physicians from 16 medical institutions throughout the nation visited the Air Force School of Aviation Medicine in Texas in November to discuss the role of civilian medicine in defense against war and disaster. The schools participating are affiliates of the Medical Education for National Defense committee, appointed by the Association of American Medical Colleges to acquaint civilian faculties with problems of military medicine and the care of mass casualties in case of a nationwide catastrophe.

The medical educators heard the latest Air Force and Navy findings on such subjects as the effects of radiation, nuclear-powered aircraft, flight fatigue, decompression sickness, and the medical problems of space flight, and they accumulated teaching material to be incorporated into the curricula at their schools. The symposium was the first of an annual series to be held at different air bases. Dr. James R. Schofield, on extended leave from Baylor University's Medical School in Houston, is national coordinator of the MEND organization, which supplies teaching materials and policy guidance to the participating schools.

PUBLIC HEALTH SERVICE

Regular Corps Examinations for Medical Officers.—An examination for appointment of medical officers to the Regular Corps of the United States Public Health Service will be held throughout the country on March 20-22, 1956. Appointments provide opportunities for career service in clinical medicine, research, and public health. Entrance pay for an assistant surgeon with dependents is $6,017 per year; for senior assistant surgeon with dependents, $6,918. Qualified officers are promoted at regular intervals. Benefits other than promotions include periodic pay increases, 30 days annual leave, sick leave, medical care, disability retirement pay, regular retirement pay, which is three-fourths of annual basic pay at time of retirement, and other privileges.

Requirements for both ranks are U. S. citizenship, age of at least 21 years, and graduation from a recognized school of medicine. For the rank of assistant surgeon, at least seven years of collegiate and professional training and appropriate experience are needed. For senior assistant surgeon, an additional three years, for a total of at least 10 years of collegiate and professional training and appropriate experience, are required.

Entrance examinations will include an oral interview, physical examination, and comprehensive objective examinations in the professional field. Application forms may be obtained from the Chief, Division of Personnel, Public Health Service, Department of Health, Education, and Welfare, Washington 25, D. C. Completed application forms must be received in the division of personnel no later than Feb. 10, 1956.

SELECTIVE SERVICE SYSTEM

Service Prospects for Interns and Residents.—The National Advisory Committee to the Selective Service System reports that the needs of the military services for medical officers from July 1, 1956, to June 30, 1957, will be of such magnitude as to require active duty of all interns and residents who have not satisfied their military liability, and perhaps some liable physicians of priority 3 who are older and who may be established in practice. In view of this it will not be possible to support deferment for any current intern for residency training except those included in the Department of Defense's residency consideration program and perhaps some interns in most exceptional situations necessary to the national health, safety, or interest. Others will be called by Selective Service as needed throughout the year, unless they voluntarily obtain commissions. The President will probably direct the Selective Service System to issue calls for physicians to enter service during the course of the hospital year, possibly in October, 1956, and January and April, 1957.

More Physicians for the Army in February.—The Secretary of Defense has requested the Selective Service System to deliver 297 physicians for induction into the Army in February, 1956.

VETERANS ADMINISTRATION

Evaluation of Mental Care.—The Veterans Administration, which has one of the nation's largest psychiatric patient loads under a single medical management, will make an extensive evaluation of mental patient care to determine what types of treatment and hospitals best promote the improvement or recovery of its psychiatric patients and the relative costs. The study will continue for five years, with probably 15 of VA's 40 neuropsychiatric hospitals participating. Dr. Jesse F. Casey, director of psychiatry and neurology service, said the information to be sought is not now available from any source.

The VA study has three purposes: (1) to determine the relative effectiveness of different treatment techniques, (2) to determine the relative effectiveness of different hospital designs, staffing patterns, and program emphases, and (3) to permit valid estimates of the relative costs of the various elements in effective treatment programs.

Dr. Richard L. Jenkins, a psychiatrist, has been appointed project director with headquarters in VA's Mt. Alto Hospital, Washington, D. C. On the advisory committee are: Dr. Harvey J. Tompkins, director, Reiss Mental Health Pavilion of St. Vincent's Hospital, New York City; Dr. Paul H. Hoch, New York state commissioner of mental hygiene; Dr. George Kelley, professor of psychology, Ohio State University, Columbus; Dr. Frank M. Le Bar, professor of anthropology, Yale University, New Haven, Conn.; and Dr. Morton Kramer, chief, biometrics branch, National Institute of Health, Bethesda, Md.

The cooperating hospitals will collaborate in a general study of admissions for a two-year period. At the time of admission, each patient will be rated as to the type and severity of illness and on other factors important for a forecast of the probability of recovery. These patients will be examined at stated intervals during the following 24 months to determine what improvement they may show and whether they are able to go home. In the intervening periods, records will be kept of the treatment measures used with each patient.

Another phase of the project will be a follow-up of patients after discharge to determine what happens to them after they leave the hospitals. This information is expected to shed light on why patients are readmitted to VA hospitals.

Advisory Research Committee.—An advisory committee on research conducted within the Veterans Administration has been appointed. It includes representatives of specialists in internal medicine, surgery, neuropsychiatry, and tuberculosis. The chairman is Dr. Joseph M. Hayman, Boston; the other members are Drs. J. Burns Amberson, New York; Carol A. Moyer, St. Louis; W. Reece Berryhill, Chapel Hill, N. C.; and Harold G. Wolff, New York City. The committee will be concerned particularly with the professional and administrative aspects of research activities conducted within VA stations and with the research activities conducted by VA employees, and also with their interpretation to the lay public. This committee will maintain contact with the committee on veterans medical problems of the National Research Council that has advised VA on matters of research since it was established in 1945.

Two Fellowships Available.—Two fellowships are available at the Fort Miley Veterans Administration Hospital, 42nd Avenue and Clement Street, San Francisco. These fellowships are by appointment from Stanford University School of Medicine, and each bears a stipend of $300 per month. The appointments are for one year and will be renewable for an additional year. Applicants must be graduates of a class-A medical school, with preference given to candidates who have adequate previous training in clinical medicine. One is a fellowship in cardiology under the auspices of the San Mateo County Heart Association, beginning July 1, 1956; the other is in hematology, beginning on the same date under the auspices of the National Institutes of Health.

DEATHS

Mackie, Thomas Turlay ⊕ Westport, Conn.; born in Great Barrington, Mass., May 10, 1895; Columbia University College of Physicians and Surgeons, New York City, 1924; received doctor of tropical medicine and hygiene degree from London School of Hygiene and Tropical Medicine, London, England, in 1931, when he received its Duncan medal; from 1926 to 1929 assistant in medicine at his alma mater, where he was instructor from 1930 to 1933 and assistant clinical professor of medicine from 1938 to 1946; research associate in public health and preventive medicine from 1933 to 1935 and associate from 1935 to 1946 at Cornell University Medical College in New York City; professor of preventive medicine and head of the department from 1946 to 1951, serving as director of the Institute of Tropical Medicine, Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, N. C.; member, subcommittee on tropical diseases, National Research Council; special consultant of the epidemiology division of the U. S. Public Health Service; served during World War I; in 1942 member of the health committee, Office for Relief and Rehabilitation, Department of State, and member of the Army Board for Investigation of Influenza and Other Epidemic Diseases; from 1940 to 1942 consultant in tropical medicine to the U. S. Secretary of War; colonel in the Medical Corps, Army of the United States, during World War II, serving as executive officer of tropical and military medicine, and chief, division of parasitology, Army Medical School; received a medal from the U. S. Army Typhus Commission; in 1946 was awarded the Legion of Merit; consultant and branch section chief, tropical medicine, Veterans Administration, branch four area from 1946 to 1949, when he became area consultant in internal medicine and tropical diseases, Veterans Administration, Atlanta area; member of the American Association for the Advancement of Science, American Clinical and Climatological Association, New York Academy of Medicine, Royal Society of Tropical Medicine and Hygiene, American Gastroenterological Association, and Alpha Omega Alpha; fellow of the American College of Physicians; past-president of the American Society of Tropical Medicine, of which he was at one time councilor and secretary, and the American Foundation for Tropical Medicine, of which he was chairman of the board; served as treasurer of the American Academy of Tropical Medicine; specialist certified by the American Board of Internal Medicine; certified by the National Board of Medical Examiners; served as a consultant to various companies in the tropics and also to the government of Surinam; did extensive survey and field work on parasitic diseases in the Caribbean region; at various times on the staffs of the Norwalk (Conn.) Hospital, Stamford (Conn.) Hospital, Presbyterian, Fifth Avenue, Roosevelt, and Beekman Street hospitals, and the Infirmary for Women and Children in New York City; joint author of "A Manual of Tropical Medicine"; chairman of the Planning and Zoning Commission; died Oct. 5, aged 60, of pulmonary embolism.

Owen, Hubley Raborg, Phoenixville, Pa.; born in Pensacola, Fla., May 8, 1883; University of Pennsylvania Department of Medicine, Philadelphia, 1905; Jefferson Medical College of Philadelphia, 1915; member of the founders group of the American Board of Surgery; at one time instructor in surgery at Jefferson Medical College; emeritus clinical professor of surgery at the Woman's Medical College of Pennsylvania; an associate member of the American Medical Association; member of the American Association for the Surgery of Trauma; fellow of the American College of Surgeons; served during World War I; three times elected president of the International Association of Police and Fire Surgeons and Medical Directors of Civil Service Commissioners, which he helped found in 1921; formerly director of public health, chairman of the local defense council, and chief surgeon of the department of public safety; for 32 years police and fire department surgeon; director of the medical division of the board of education, a post held until 1950, when he became executive director and later president of the Philadelphia Heart Association; consulting surgeon, Philadelphia General Hospital; recently cited by the Health and Welfare Council for "outstanding contributions to health" in Philadelphia; in 1943 received the 20th annual Strittmatter award of the Philadelphia County Medical Society; died in Bryn Mawr (Pa.) Hospital Oct. 8, aged 72.

Bishop, Robert Hamilton Jr., Cleveland; born in 1879; Western Reserve University Medical Department, Cleveland, 1908; director of the joint committee for the advancement of medical education and research of the Western Reserve University School of Medicine and affiliated hospitals; past-president of the Ohio Public Health Association; member of the Ohio State Medical Association; served as president of the American College of Hospital Administrators; at one time city health commissioner; last May was awarded William Freeman Snow medal by the American Social Hygiene Association for distinguished service to humanity; a founder of the National Conference of Tuberculosis Workers and a past member of the board of directors of the National Tuberculosis Association; served as the first full-time executive secretary of the Anti-Tuberculosis League of Cleveland and Cuyahoga County and as president of the Ohio Tuberculosis and Health Association; for many years medical director of the University Hospitals; died in Novelty, Ohio, Sept. 29, aged 76, of arteriosclerosis.

Zavin, William Herman ⊕ Portland, Ore.; University of Oregon Medical School, Portland, 1938; certified by the National Board of Medical Examiners; specialist certified by the American Board of Pediatrics; fellow of the American Academy of Pediatrics; past-president of the Portland Academy of Pediatrics; clinical instructor in pediatrics at his alma mater; on the staffs of the Providence, Emanuel, and Good Samaritan hospitals and the Portland Sanitarium; at one time associated with the city bureau of health as director of the communicable diseases section; died in Kirkland, Wash., Oct. 5, aged 43.

Adams, Herman Galusha, Ramona, Calif.; Starling Medical College, Columbus, 1898; died Sept. 15, aged 97.

Blackwell, George Thomas, Gorman, Texas; Chicago College of Medicine and Surgery, 1908; served as mayor, and for many years a member of the school board; died June 13, aged 73, of coronary occlusion.

Bonar, Edward Twinem ⊕ Columbus, Ohio; Ohio State University College of Medicine, Columbus, 1947; interned at the Mount Carmel Hospital in Columbus, where he served a residency; died Sept. 28, aged 32.

Carr, Charles Clay ⊕ Pennington Gap, Va.; Lincoln Memorial University Medical Department, Knoxville, Tenn., 1915; served during World War I; past-president of the Lee County Medical Society; past-president of the Pennington Gap Lions Club; died in the Harlan (Ky.) Hospital Sept. 29, aged 69, of urinary tract infection.

Case, Carl Judd ⊕ Los Gatos, Calif.; Western Reserve University Medical Department, Cleveland, 1910; member of the Ohio State Medical Association; died in the O'Connor Hospital, San Jose, July 8, aged 73, of duodenal ulcer.

Chambers, Merritt Goodrich, Pittsville, Md.; New York Homeopathic Medical College and Hospital, New York City, 1902; died Sept. 10, aged 78, of a heart attack.

Coyle, Bruce James, Windsor Locks, Conn.; Georgetown University School of Medicine, Washington, D. C., 1918; member of the Connecticut State Medical Society; died Aug. 5, aged 65, of coronary occlusion.

DeFuccio, Charles Pasquale ⊕ Jersey City, N. J.; University and Bellevue Hospital Medical College, New York City, 1914; specialist certified by the American Board of Pediatrics; member

---

⊕ Indicates Member of the American Medical Association.

of the American Academy of Pediatrics; medical supervisor of schools in Jersey City; on the staff of the Jersey City Medical Center and St. Francis' Hospital; died Oct. 9, aged 66, of coronary thrombosis.

Dick, Noble ⊕ Santa Rosa, Calif.; Medical College of the State of South Carolina, Charleston, 1924; on the staff of the Santa Rosa Memorial Hospital; died Sept. 26, aged 63, of pulmonary fibrosis.

Dougan, Archie Longshore ⊕ Carmen, Okla.; Kansas City (Mo.) Medical College, 1897; died in Grand Junction, Colo., Sept. 27, aged 86, of pneumonia.

Edrington, Nicholas Kuntz, New Orleans; Vanderbilt University School of Medicine, Nashville, Tenn., 1916; fellow of the American College of Allergists and member of the Louisiana State Medical Society; past-president of the Louisiana Allergy Society; medical examiner for the Orleans Parish school board; for many years an examiner for the induction center of Selective Service; served during World War I; at one time physician for the Louisiana boxing commission; on the staff of the Baptist Hospital; died Sept. 22, aged 65.

Edwards, Francis Main ⊕ Cisco, Ill.; St. Louis College of Physicians and Surgeons, 1898; veteran of the Spanish-American and World Wars; for many years practiced in New Baden, where he was president of the Farmers State Bank; consulting surgeon at Centralia for Southern Railway; surgeon-in-chief emeritus at St. Mary's Hospital in Centralia, where he died Oct. 17, aged 79, of myocarditis and arteriosclerosis.

Firfer, Bourke ⊕ Chicago; University of Illinois College of Medicine, Chicago, 1938; interned at the Jackson Park Hospital; served a residency at the South Shore Hospital, where he was vice-president of the medical staff, and where he died Oct. 13, aged 42, of cerebral embolus and myocardial infarction.

Fischer, Nathaniel Arthur, Pittsburgh; University of Pittsburgh School of Medicine, 1908; clinical professor emeritus of otology at his alma mater; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; on the staffs of the Eye and Ear Hospital and St. Francis Hospital; died in the W. A. Foote Memorial Hospital, Jackson, Mich., July 28, aged 69, of coronary thrombosis and hypertension.

Flynn, James Lawrence ⊕ Natick, Mass.; Georgetown University School of Medicine, Washington, D. C., 1939; specialist certified by the American Board of Ophthalmology; on the staffs of the Boston City Hospital and St. Elizabeth's Hospital; died in the Haynes Memorial Hospital, Brighton, Sept. 26, aged 44, of bulbar poliomyelitis.

Fodder, William Lewis, Schenectady, N. Y.; Albany (N. Y.) Medical College, 1897; an associate member of the American Medical Association; fellow of the American College of Surgeons; honorary staff member at Ellis Hospital; past-president and secretary of the Schenectady County Medical Society; veteran of the Spanish-American War; died Sept. 6, aged 79, of acute bronchitis and arteriosclerosis.

Ford, Walter David ⊕ Dearborn, Mich.; Detroit College of Medicine, 1899; fellow of the American College of Physicians; served during World War I; at one time on the faculty of his alma mater; on the staff of the Harper Hospital, where he died Oct. 12, aged 76, of adenocarcinoma of the rectum with metastases.

Freydberg, Max, Mahopac, N. Y.; University of Odessa Faculty of Medicine, Russia, 1915; Howard University College of Medicine, Washington, D. C., 1924; member of the Medical Society of the State of New York; died July 5, aged 62, of coronary thrombosis and arteriosclerosis.

Gale, Clinton Fifield, Georgetown, N. Y.; University of Vermont College of Medicine, Burlington, 1905; member of the Medical Society of the State of New York; died in the Marcy (N. Y.) State Hospital July 30, aged 76, of arteriosclerotic heart disease.

Gerberich, Guy A., Lebanon, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1907; died Aug. 14, aged 72, of cerebral thrombosis.

Gladman, Everett Aldrich, Fulton, N. Y.; McGill University Faculty of Medicine, Montreal, Canada, 1898; medical consultant to the Oswego County Welfare Association; an associate member of the American Medical Association; member of the American Academy of General Practice; past-president of the Oswego County Medical Society; on the staff of the Albert Lindley Lee Memorial Hospital; died in the Syracuse (N. Y.) Memorial Hospital July 18, aged 80, of plasma cell myeloma.

Grimes, James Thomas ⊕ Philadelphia; Jefferson Medical College of Philadelphia, 1939; served during World War II; on the staffs of the Frankford and Nazareth hospitals; died Oct. 4, aged 41, of carcinoma of the pancreas.

Gummey, Frank Bird ⊕ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1888; an associate member of the American Medical Association; served during World War I; died Sept. 3, aged 88.

Gute, Edwin Bertram ⊕ Whitefish Bay, Wis.; Rush Medical College, Chicago, 1926; served during World War I and World War II; in 1916 served in the U. S. cavalry on the Mexican border; health commissioner in Whitefish Bay from 1927 to 1943; health commissioner of Fox Point since 1933 and of Bayside since 1953; member of the American Public Health Association and the American Association of School Physicians; died in Milwaukee July 15, aged 58, of cerebral thrombosis.

Hunter, Rush Quinn ⊕ Palestine, Texas; University of Texas School of Medicine, Galveston, 1922; fellow of the American College of Surgeons; chief of staff of the Memorial Hospital; died Sept. 19, aged 57, of coronary thrombosis.

Hutchins, Eugene Leslie, North New Portland, Maine; Medical School of Maine, Portland, 1915; member of the Maine Medical Association; on the staff of the Franklin County Memorial Hospital in Farmington; died Sept. 28, aged 66, of myocardial infarction.

Keim, William W., Davidsville, Pa.; Baltimore Medical College, 1905; past-president of the Somerset County Medical Society; served on the staff of the Memorial Hospital in Johnstown; died Aug. 7, aged 76, of chronic fibrous pancreatitis.

Klein, Benjamin D., New York City; Long Island College Hospital, Brooklyn, N. Y., 1923; died in St. Clare's Hospital Sept. 27, aged 58, of massive gastrointestinal hemorrhage and duodenal ulcer.

Latte, David, New York City; Julius-Maximilians-Universität Medizinische Fakultät, Würzburg, Bavaria, Germany, 1904; died in Saratoga Springs, N. Y., July 29, aged 77, of arteriosclerotic heart disease.

Lomnitz, Friedrich Walter ⊕ New York City; Kaiser-Wilhelms-Universität Medizinische Fakultät, Strassburg, Germany, 1918; died Oct. 11, aged 66, of a heart attack.

Lowder, Lillian Crockett, Indianapolis; Central College of Physicians and Surgeons, Indianapolis, 1898; died Sept. 19, aged 85, of cardiac decompensation.

MacCracken, S. Gordon, Ashland, Ore.; the Hahnemann Medical College and Hospital, Chicago, 1894; served during World War I; died Sept. 16, aged 85, of arteriosclerosis.

Merwin, Edgar Garfield ⊕ Highland, Ill.; Washington University School of Medicine, St. Louis, 1907; for many years served on the board of education and board of health; on the staff of St. Joseph's Hospital, where he died Sept. 30, aged 76, of uremia, hypertension, and arteriosclerosis.

Miller, Victor Davis ⊕ Hagerstown, Md.; University of Pennsylvania Department of Medicine, Philadelphia, 1900; served as secretary of the Washington County Medical Society; member and past-president on the staff of the Washington County Hospital, where he died Sept. 21, aged 79, of acute coronary occlusion.

Myers, Harry Edwin ⊕ Columbus, Ohio; Starling Medical College, Columbus, 1907; member of the American Academy of General Practice; served during World War I; on the staffs of St. Ann's Hospital, Mercy Hospital, and the Mount Carmel Hospital, where he died Sept. 26, aged 75, of a heart attack.

Opitz, John Hoff ⊕ Chicago; Loyola University School of Medicine, Chicago, 1917; on the staffs of the German Deaconess and Southtown hospitals; died Oct. 16, aged 62, of heart disease.

Petty, Clarence Sibley ⊕ Guthrie, Okla.; Chicago Homeopathic Medical College, 1897; on the staffs of the Benedictine Heights Hospital; died Sept. 25, aged 83, of congestive heart disease.

Price, Byron Sprague, Port Chester, N. Y.; McGill University Faculty of Medicine, Montreal, Canada, 1895; was a member of the Radiological Society of North America; an associate member of the American Medical Association; died Sept. 17, aged 83, of arteriosclerosis.

Puris, Abram Martin, Park Ridge, Ill.; University of Nebraska College of Medicine, Omaha, 1919; specialist certified by the American Board of Pediatrics; for many years on the staff of the Children's Memorial Hospital in Chicago; died July 15, aged 60.

Rawson, Elwin Gilbert, Anamosa, Iowa; the Hahnemann Medical College and Hospital, Chicago, 1911; for many years health officer; died Sept. 16, aged 70, of coronary occlusion.

Robinson, Edward Jerome, Chicago; Chicago Medical College, 1920; died Oct. 2, aged 80.

Rosenberg, Harry ⊕ Chicago; Chicago Medical School, 1929; member of the American Academy of General Practice; on the staff of the Edgewater Hospital; died Sept. 18, aged 57, of cerebral hemorrhage.

Rosenblate, Adolph Jan ⊕ Chicago; University of St. Vladimira Faculty of Medicine, Kiev, Russia, 1928; specialist certified by the American Board of Radiology; member of the American College of Radiology; served on the staffs of the American, Englewood, and Evangelical hospitals; died in the Columbus Hospital Oct. 12, aged 61.

Roth, Norman, New York City; Long Island College Hospital, Brooklyn, N. Y., 1906; member of the Medical Society of the State of New York; died Aug. 9, aged 73, of coronary thrombosis.

Sandroni, Dino ⊕ New York City; Columbia University College of Physicians and Surgeons, New York City, 1921; member of the National Gastroenterological Association; on the staffs of the University and Roosevelt hospitals; died in the Memorial Hospital Aug. 24, aged 57, of leukemia.

Schipfer, Lloyd Albert ⊕ Chicago; State University of Iowa College of Medicine, Iowa City, 1907; specialist certified by the American Board of Otolaryngology; fellow of the American College of Surgeons; on the staff of the Wesley Memorial Hospital; died in the Evanston (Ill.) Hospital Oct. 15, aged 71, of thrombosis of the basilar artery and arteriosclerosis.

Sell, Oliver Martin ⊕ Pittsburgh; University of Pittsburgh School of Medicine, 1927; specialist certified by the American Board of Surgery; member of the American Society of Anesthesiologists; fellow of the American College of Surgeons; on the faculty of his alma mater; served during World War II; on the staffs of the Suburban Hospital in Bellevue and the Presbyterian and Woman's hospitals; died in Myrtle Beach, S. C., Sept. 22, aged 51, of coronary thrombosis.

Shabat, Louis Willard ⊕ Chicago; University of Illinois College of Medicine, Chicago, 1931; assistant professor of surgery at the Chicago Medical School; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; served during World War II; on the staffs of the Mount Sinai, Edgewater, and Cook County hospitals; died Oct. 21, aged 47.

Silverman, Harry Zeleck, Miami Beach, Fla.; Tufts College Medical School, Boston, 1924; an associate member of the American Medical Association; served during World Wars I and II; on the staff of Mount Sinai Hospital; died Oct. 3, aged 57, of coronary thrombosis.

Slavin, Francis James ⊕ Sunnyvale, Calif.; University of Cincinnati College of Medicine, 1944; served during World War II and the Korean war; died Sept. 22, aged 37.

Smith, French Nestor, Harlingen, Texas; Eclectic Medical Institute, Cincinnati, 1921; died July 10, aged 64, of cancer.

Smith, James Westphal Barnum ⊕ Albion, Neb.; University of Nebraska College of Medicine, Omaha, 1903; served as secretary-treasurer of the Boone County Medical Society; died Aug. 28, aged 78.

Stephens, George Henry, Syracuse, N. Y.; Syracuse University College of Medicine, 1903; an associate member of the American Medical Association; at one time fire and police surgeon; on the staffs of the University and People's hospitals; died in Thousand Island Park, N. Y., Aug. 3, aged 80, of carcinoma of the lung.

Stevens, Delos Meeker ⊕ Oskaloosa, Kan.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1912; past-president and secretary of the Jefferson County Medical Society; died in the Lawrence (Kan.) Memorial Hospital Sept. 2, aged 65, of cerebral hemorrhage.

Straw, Zatae Longsdorf ⊕ Manchester, N. H.; Woman's Medical College of Pennsylvania, Philadelphia, 1890; spent some time in a government hospital for Indians in Idaho before going to Manchester; served in the state legislature; in 1937 received the honorary degree of doctor of science from Dickinson College, Carlisle, Pa.; died Oct. 1, aged 89.

Tingdale, Carlyle ⊕ Hibbing, Minn.; University of Minnesota Medical School, Minneapolis, 1938; interned at the Minneapolis General Hospital; health officer and school physician; accidentally drowned in Lake Vermillion Aug. 12, aged 47.

Todd, Lawrence Newton, Berry, Ky.; University of Louisville (Ky.) Medical Department, 1912; member of the Kentucky State Medical Association; served in France during World War I; died July 28, aged 65, of coronary occlusion.

Torrey, John Paine ⊕ Bartlesville, Okla.; Harvard Medical School, Boston, 1896; veteran of the Spanish-American War and World War I; on the staff of the Washington County Memorial Hospital, where he died Oct. 1, aged 85, of Buerger's disease.

Trice, Ernest T., Richmond, Va.; University College of Medicine, Richmond, 1911; member of the Medical Society of Virginia; fellow of the American College of Surgeons; from 1937 to 1939 served on the state prison board; served during World War II; on the staffs of the Medical College of Virginia and Grace hospitals; died Sept. 7, aged 67, of metastasis from a Pancoast tumor of the left lung.

Ussher, Clarence D. ⊕ Santa Monica, Calif.; University Medical College of Kansas City, Mo., 1896; at one time a medical missionary in Turkey and Armenia; died Sept. 20, aged 85, of chronic endocarditis.

Weeks, Paul Richard ⊕ Denver; Indiana University School of Medicine, Indianapolis, 1927; specialist certified by the American Board of Radiology; member of the Radiological Society of North America and American Radium Society; fellow of the American College of Radiology; served during World War II; on the staffs of the Presbyterian Hospital, St. Luke's Hospital, and St. Joseph Hospital, where he died Sept. 20, aged 53, of carcinoma of the pancreas.

Wheeling, William Stuart, Windber, Pa.; Jefferson Medical College of Philadelphia, 1893; an associate member of the American Medical Association; member of the American College of Chest Physicians, American Trudeau Society, and the International College of Surgeons; on the staff of the Windber Hospital; died Sept. 13, aged 82, of myocarditis.

Williams, Frederic Darbey, Valley Falls, R. I.; Columbia University College of Physicians and Surgeons, New York City, 1903; died in the Pawtucket (R. I.) Memorial Hospital Sept. 12, aged 77.

Woolley, Talmage Oliver, Orange, Texas; University of Texas School of Medicine, Galveston, 1911; member of the State Medical Association of Texas; died in the Lutcher Hospital Sept. 21, aged 71, of coronary thrombosis.

FOREIGN LETTERS

BRAZIL

Pulmonary Syphilis.—Dr. A. Guimarães Barbosa reported on a patient in whom the clinical findings, positive serologic tests for syphilis, and results of the therapeutic test led to a diagnosis of the gummatous form of pulmonary syphilis (*Rev. paulista de tisiol.* 16:93, 1955). Although acquired syphilis of the lung is regarded by many pathologists as rare, many cases have been reported by clinicians. There is no agreement about its incidence, but there is general agreement about the morbid anatomy seen in the fetus or newborn infant with this condition. In addition to the gummatous form, there is an interstitial pneumonic form. The physical findings are not typical in this form but are those of many other pulmonary diseases. The radiographic findings are likewise inconclusive. The clinical diagnosis is made by serologic tests, therapeutic tests, and by excluding other conditions.

Schistosomal Myelitis.—A fatal case of transverse myelitis of schistosomal origin was observed by Dr. Zacarias Maciel and co-workers of the medical school of the University of Recife. The patient was admitted to the hospital because of total loss of motor control in the lower extremities, incontinence of urine and feces, and a temperature of 100.4 F (38.0 C). Tendinous areflexia with muscular hypotonia and hypesthesia in the lower extremities and a bilateral Babinski sign were noted on examination. The patient died 10 days after admission. At autopsy, microscopic sections of the lumbar region of the spinal cord showed thromboses, hemorrhages, inflammatory reactions, and Schistosoma mansoni ova in direct relation to the lesions. Arteriolar lesions were characterized by necrosis, endarteritis, with edema and leukocytic infiltration, and periarteritis. The nervous tissue in the lumbar region showed severe myelitic disintegration throughout the white matter, ischemic degeneration of the neurons, one small area of gliosis, local destruction of myelin in the radicular branches, and, in one of these branches, the shells of Schistosoma ova.

ENGLAND

Lung Cancer, Polluted Air, and Smoking.—Stocks and Campbell have reported an investigation to evaluate the effects of tobacco smoking and air pollution by benzpyrene acting together on the men in rural North Wales and urban Liverpool (*Brit. M. J.* 2:923, 1955). The intention was to carry out a five year study, but the results so far obtained have been presented because they point strongly to measures that might help to reduce the incidence of pulmonary cancer. Since 1952 the authors have collected the environmental histories of a number of male residents in the two areas who were believed to be suffering from any form of malignant disease. Reports were also obtained of all deaths certified as due to cancer, and, if no history taken during life was available, a relative was questioned. Supplementary information on the basis of diagnosis, duration of symptoms, and the patients' smoking habits were obtained. About 12,000 histories were also recorded of patients without cancer. Careful analyses of air samples from the areas were made and studied for 3:4-benzpyrene, 1:12-benzperylene, pyrene, fluoranthene, anthracene, and sulfur dioxide. From a previous finding that 4 mcg. of 3:4-benzpyrene can be extracted from the smoke of 500 cigarettes, together with the amount of this substance in air as determined by the same technique, it was possible to estimate what would be the total intake of benzpyrene per year by men of different smoking habits living in rural and urban areas.

The death rates from cancer of the lung and bronchus were calculated among men, aged 45 to 74 years, of different smoking habits, as were the death rates related to the probable amounts of benzpyrene and other carcinogens inhaled from the air. The annual male mortality from lung cancer in the Welsh rural areas increased steadily from 14 per 100,000 for nonsmokers to 363 per 100,000 for heavy smokers (based on a consumption of more than 250 cigarettes a week for 10 years). The corresponding mortality for pipe smokers, irrespective of the amount smoked, was 41 per 100,000. Similar figures were obtained for mixed urban and rural areas, but, in Liverpool, with its greater atmospheric pollution, the mortality rate of nonsmokers was 131 per 100,000 and up to 394 per 100,000 for smokers. Actually, the death rate increased proportionately to the number of cigarettes smoked per week; pipe smokers as a group ranked with cigarette smokers of about 25 a week. The urban rates exceeded the rural rates in every smoking category. The absolute urban excess of deaths was much the same in each smoking group, suggesting that an atmospheric factor is added to the effects of smoking. The authors estimate that 50% of the deaths of Liverpool men from lung cancer arise from cigarette smoking and about 75% of the remaining half are due to a factor only slightly present in the rural areas. The concentration of smoke and 3:4-benzpyrene in Liverpool air was about 10 times as great as that of the rural districts. Benzpyrene is believed to be the carcinogen responsible for the association of lung cancer with both smoking and living in towns.

First Seven Years of National Health Service.—The John Tate Memorial Lecture was delivered before the Middlesex County Medical Society by Dr. T. R. Hill who discussed the lessons learned in the National Health Service since it began seven years ago. He said that the cost of the service was now so high that it had become almost a political issue. The cost was one of the most colossal miscalculations ever made. As medicine advances, costs in publicly organized health service must necessarily increase. The increasing age of the population was not adequately considered, but, because of it, the service will be called on increasingly to deal with the degenerative diseases of later life. Yet, in 1948, the main theme was the economy that would result from the increase in the working strength of a people for whom medical advice and treatment would be freely available. The problem now is how to control rising costs and reduce economic damage to the country. Some form of highly competent central control is necessary. The spread of consultant services all over the country, instead of localization in a few large towns, is of great benefit to the patient, and young physicians are in a better position financially than were their predecessors. Insufficient attention, however, was paid to the general practitioners, many of whom complain that they have lost status and are only routine suppliers of certificates and prescriptions. At present, a physician is not fit to enter general practice on graduation from a medical school. The qualified physician of tomorrow must be more highly trained than he is today. Greater care in selecting medical students should be exercised to insure more competent general practitioners. A raising of the standard of qualification is essential. The general practitioner should have hospital experience under skilled supervision. Too many patients are sent to the hospital, both as inpatients and outpatients. A larger number could be treated at home and hospital beds released for the more needy. Specialists spend too much time seeing outpatients who should not have been sent to them. More money should be spent on home treatment.

Dr. Hill could not understand why the government made so much fuss about overprescribing in general practice, which was a mere bagatelle in comparison with hospital costs (about one billion dollars per annum). Constructive hospital planning has been grossly inadequate. The Central Health Services Council, set up to advise the Ministry of Health, has failed because it was not representative of the medical profession. The profession, not a government department, should choose its own advisory body. There is too great a concentration of power in persons and groups. The central government has given too much responsibility to regional boards without considering the part the profession could itself play.

The items in these letters are contributed by regular correspondents in the various foreign countries.

Hypophysectomy for Diabetes.—In an attempt to arrest the progress of diabetic retinal, vascular, and renal complications, Professor Olivecrona and his co-workers have carried out hypophysectomy on 20 diabetic patients between the ages of 20 and 23 (*Brit. M. J.* 2:752, 1955). All patients had diabetic retinopathy, elevated blood pressure, and proteinuria. The purpose of the operation was to eliminate those anterior pituitary factors that animal experiments have shown possess a diabetogenic action, as it was thought that these hormones might be connected with the development or progression of diabetic complications. Reports are available on 19 of the patients. Two died within the first postoperative week, and two died within a month, one from thrombosis in the leg and one in an epileptic state presumably caused by hypoglycemia. One patient died 6 months later from progressive mental deterioration associated with arteriosclerosis and not the operation; one 15 months after operation from hypertensive crisis; and one 19 months after operation from renal insufficiency. After the initial postoperative period the patients were given protamine zinc insulin, a diet of 1,400 to 2,000 calories daily, thyroxin, estrogens, or androgens, and desoxycorticosterone, or corticotropin. In the 13 surviving patients the operation was followed by a fall in blood pressure and a decrease in cardiac volume. Where calcification of the peripheral vessels existed before operation of the patients, blood pressure and cardiac volume were not affected, but no calcification occurred in other patients. A definite decrease in proteinuria and in the glomerular filtration rate was achieved, but the effective renal plasma flow was unchanged. This was believed to indicate a favorable effect on the renal circulation. No signs of progression of the renal disease were observed. The renal capacity improved in some patients, and the retinal changes did not progress. Because of the limited period of observation (3 to 43 months) and the small number of patients, definite conclusions could not be reached. However, the high mortality makes the operation a desperate measure. Success is by no means certain, although at the moment no other treatment to arrest complications has anything to offer. Some form of irradiation might be a safer alternative.

Herniorrhaphy as an Outpatient Procedure.—Early ambulation after operations was advocated at the end of the last century and has generally gained acceptance. Impressed with the advantage of early ambulation and the long hospital waiting lists —there are currently 447,000 patients awaiting admission for 76,000 beds in England and Wales—Dr. E. Farquharson decided to perform inguinal herniorrhaphy as an outpatient procedure. Most of his patients had been placed at the end of surgical waiting lists because it was argued that their operation was not urgent. He presented his results in 485 patients whose inguinal hernias were treated in this way (*Lancet* 2:517, 1955). Had they been admitted in the usual way, they would have filled a 28-bed ward continuously for six months at a cost of $21,000 to $28,000. The operations were carried out under local analgesia without an anesthetist. The patients were little disturbed by the operation. They walked out of the operating room, dressed, and walked to the cars or ambulances taking them home, the aim being to get them back to their own beds before the local analgesia wore off. They were told to spend the next three or four days in bed, with toilet privileges granted, and to return to the hospital in eight or nine days for removal of stitches. Dr. Farquharson uses this procedure only in patients with satisfactory home conditions and provided that the hernia is neither large nor irreducible. The ages of the patients ranged from 12 to 83 years. The best results, judged by freedom from complications, were in the elderly, who prefer the comforts of home. Retention of urine was not noted in any of these patients. The cooperation of the patient's physician was obtained, and he visited in the first few days the patient was home. Arrangements were made for immediate admission in the event of any complications; only 11 of the 485 needed admission for this reason. This was reduced to 1 in the last 200 patients. A follow-up examination suggests that the results are as good as with orthodox hospitalization.

Osler Memorial at Oxford.—On Oct. 8, Prof. G. W. Pickering unveiled a memorial plaque on the outer wall of a house at Oxford in Norham Gardens, which Sir William Osler occupied during his 12 years as regius professor of medicine and in which he died in 1919. Mr. V. Green-Armitage, president of the Osler Club, which provided the plaque, said that he was one of the remaining few who had known Osler and that he had been presented with a prize 50 years ago by Osler. The Osler Club was founded in the early 1920's by a small band of his students. Osler came to Oxford from Johns Hopkins just 50 years ago. The house in which he lived was bequeathed to the university by Lady Osler in 1928 as an official residence for regius professors, but owing to its large size—it had 14 bedrooms—it was not used for a time. The problem was solved by converting it into apartments, one of which would be available to future regius professors. Professor Pickering said that Osler did his best work and researches on diseases of the spleen, blood, and heart in North America. He was successively professor at McGill, the University of Pennsylvania, and Johns Hopkins. Probably no other institution in the world has had such an effect on medical education as Johns Hopkins Medical School. Osler was 56 years old when he came to Oxford. No other personality in the medical world during the present century has had his memory perpetuated in Britain in the same way as Osler. He was a great physician, a great teacher, and a great scholar. It is because he always had time for his students and was a student at heart that the Osler tradition has persisted.

National Health Service in Northern Ireland.—The Northern Ireland General Health Services Board has issued its report for the period 1954-1955 (Northern Ireland General Health Services Board, Seventh Annual Report Year 1954-1955, Belfast, Ireland, Her Majesty's Stat. Off.). The number of persons under treatment by general practitioners in the National Health Service has increased from 1,362,745 to 1,369,115 (98.96% to 99.23% of the total population); the average number per physician decreased from 1,906 to 1,883, mainly because of the increase in the number of physicians in large practices; the number of medical partnerships increased from 122 to 135; and the number of physicians in partnership practice increased from 255 to 282. The medical adviser said that he had found the general standard of accommodation and equipment in physicians' offices to be satisfactory and that many physicians had made improvements. During the year complaints against six doctors were investigated, but only three were substantiated. Twenty-two complaints were dismissed without investigation. The number of patients changing their doctors for reasons other than change of address of physician or patient rose from 1,604 to 20,405.

Influenza in the United States and Great Britain.—Observations on the epidemiology of influenza in the United States and Great Britain have been made by Drs. Davenport, Hennessy, and Francis of the University of Michigan in collaboration with Prof. Stuart Harris of the University of Sheffield. Comparison of antibody levels observed with prototype strains of influenza viruses in serums collected from persons in Sheffield and Michigan showed that similar shifts of dominance of the antigens that comprise group A influenza viruses occurred in both countries at the same time. Levels of antibody to type A strains were much lower in persons in Sheffield. This may help to explain the higher incidence of influenza in Great Britain than in the United States. Since 1932 the annual case fatality rates from influenza in Great Britain have been consistently greater than in the United States. In 1951 there was a severe epidemic in Great Britain but only a mild one in the United States.

Compulsory Hospitalization for Tuberculosis.—The magistrates of Haverfordwest, Wales, have ordered the compulsory hospitalization of a laborer with four children who had not worked for some time and who had pulmonary tuberculosis. A few weeks after this laborer had been admitted to hospital, he had left against medical advice and returned home. Although he was a source of infection, he used public transportation. He refused to return to hospital despite urging by his physician, the district nurse, county health officer, and chest clinic physician. Under the Public Health Act, 1936, the magistrates ordered his removal to the hospital for three months. Although this is the maximum period of detention allowed, renewal of this period can be ordered subsequently if necessary. Although the Public Health Act has been in effect for nearly 20 years, it is seldom invoked.

Harmful Effects of Exhaust Fumes.—Experts from the poison gas defense station at Porton are collaborating with a panel of investigators appointed by the Medical Research Council to examine the toxic and possible carcinogenetic effect of exhaust fumes from automobiles, trucks, and busses. These fumes may be responsible for the increase in lung cancer, bronchitis, and certain nerve diseases. Benzpyrene has already been found by Dr. A. Lindsey in the deposit from diesel exhaust pipes, and detectable amounts of lead, derived from the tetraethyl lead put in gasoline to stop knocking, have been found in the air. Dr. E. Wilkins of Greenwich is measuring the amount of carbon monoxide derived from gasoline and diesel-driven engines in London streets. Dangerously high amounts have been found in Blackwall Tunnel, which passes under the Thames in East London.

Tuberculosis Due to Resistant Organisms.—McMurdoch and Grant reported on a patient with pulmonary tuberculosis from whom organisms resistant to streptomycin and isoniazid were isolated, although he had received no previous chemotherapy with either drug (*Lancet* 2:587, 1955). The 20-year-old patient had a sister who had been treated with *p*-aminosalicylic acid alone, streptomycin alone, and isoniazid alone. Nine sputum specimens were all positive for Mycobacterium tuberculosis on culture, and all showed the bacilli to be resistant to streptomycin and isoniazid. The patient was therefore given 2 gm. of viomycin twice weekly and 4 gm. of oxytetracycline daily for two months, when the sputum became negative.

Radioactive Cesium.—Liverpool Radium Institute has received authority from the Regional Hospitals Board to treat patients with radioactive cesium, a by-product of atomic fission. The new therapeutic unit will cost $28,000. The extraction of radioactive cesium is carried out at the atomic energy factory at Windscale. The cesium capsules have an activity of 1 kg. of radium, that is, 1,000 curies. The initial production rate will be one or two capsules a month. The United States is the only other country making radioactive cesium on this scale.

James Parkinson.—On Sept. 17, a memorial plaque to James Parkinson, author of "Essay on the Shaking Palsy," was unveiled in the church of St. Leonard's, Shoreditch, London. Parkinson was also known for his work on political and social reform and on geology. He had the ability to simplify abstract ideas and present them in plain words. Politically he was a Socialist, which is not surprising, as he worked in the slums. The plaque replaces Parkinson's tombstone, which was destroyed in the bombing of London.

Magnetic Call System.—At St. Thomas's Hospital, London, a magnetic call system for contacting resident medical staff is being installed. By this system, which it is believed St. Thomas's is the first hospital to introduce, it is possible to contact a physician in any part of the hospital through signals on a small wireless receiver that is carried in the breast pocket.

FINLAND

Drug Addiction in Finland.—At a meeting of Scandinavian pharmacologists in Helsinki, Professor Möller of Copenhagen, Denmark, stated that, in relation to drug addiction, the term euphomania is preferable to the term narcomania as the former embraces drugs other than narcotics. It covers, for example, the amphetamine group. It is doubtful, however, if either of these terms will altogether replace the term drug addiction. Dr. A. Huhtala, on the staff of a prison in Helsinki, said that in 1939 tablets containing heroin were issued by the Army Medical Service liberally and without strict precautions being taken to prevent abuses. This led to the creation of a number of drug addicts whose histories may be found in hospital and police records. Since World War II there has been a marked decline in the consumption of both heroin and morphine, but Finland's consumption of heroin is still many times greater than that of Denmark. There are about 200 drug addicts in Helsinki and 100 more in the rest of Finland. About one-third to one-quarter of these are women, and about 20 physicians and the same number of nurses and druggists are addicts. In Helsinki several drug addicts have joined forces in order to help each other in securing the drugs they need. There has been a curious shift in the preference shown by addicts for one drug after another. Many begin with heroin, switch to morphine, and end with methadone. At present, methadone has almost completely replaced both heroin and morphine. A morphine or heroin addict can achieve complete satisfaction by switching to methadone, but a chronic methadone addict is uncomfortable if he switches to morphine, even in small doses. These drugs are now almost exclusively taken intravenously, and, when large doses of methadone are given subcutaneously, troublesome sores with sinuses in situ are apt to appear. Among the more than 50 drug addicts examined by Huhtala since April, 1953, there was only one morphine addict—a woman; all the rest were methadone addicts. The most characteristic symptom of methadone addiction is complete sleeplessness. Drug addiction is no longer a serious social problem in Finland, with the possible exception of Helsinki, in one of whose prisons 98 addicts have been treated between 1948 and 1954. Present legislation makes no provision for the compulsory supervision and treatment of drug addicts as such. Legislation against vagrancy may in some cases be invoked in dealing with addicts who may also fall foul of the law by forging medical certificates. There appears to be no serious smuggling of drugs into Finland.

FRANCE

Delirium Tremens.—At a meeting of the Medical Society of Paris Hospitals on June 17, A. Ravina and his co-workers stated that of 2,237 men admitted to the general medical service, 1,500 were alcoholics and that 124 of 300 who came to autopsy had alcoholic cirrhosis. The authors treated 140 patients with delirium tremens. A diet deficient in proteins and fats was a contributing factor. In 10 patients the onset followed a pulmonary infection; in 4 it followed trauma; in 8 it followed sudden abstinence from alcohol; and in 14 no precipitating factor could be found. The prognosis is poor in those who have elevation of temperature, tachycardia, or bradycardia and in patients over 60 years of age in whom there is a drop in arterial pressure. A prothrombin rate below 90% without any other humoral modifications was observed in many of these patients. The authors recommended giving 50 mg. of chlorpromazine two or three times in 24 hours, 10 mg. of strychnine by injection twice in 24 hours, and 10 to 20 cc. of 3% alcohol intravenously. They avoid barbiturates but give alcohol and Phenergan instead. Of their 40 patients treated in this manner, 38 recovered. If there is evidence of cerebral edema, magnesium sulfate and the adrenocortical hormones are given.

Heparin for Cold Abscesses.—In the *Official Bulletin of the Medical Society of Physicians* for June, 1954, Weil and Murat reported that they had injected 50 mg. of pure heparin into a cold abscess. This prevents the caseous liquefaction of the tissues that is provoked by proteolytic enzymes and also the coagulation of the serous exudate. Healing occurs in 15 to 20 days after several injections. The results are better if isoniazid and streptomycin are also used. The heparin permits the antibiotics to penetrate into the center of the abscess even when the abscess is large.

Oxytetracycline for Rheumatic Fever.—J. Billiottet and his coworkers treated 54 patients with rheumatic fever with intravenous perfusions of 300 to 750 mg. of oxytetracycline daily. In children and in serious cases, they have also given cortisone. The results were presented to the Medical Society of Paris Hospitals on June 24. One patient so treated had cardiac complications. Of the 32 patients followed for at least two years, recurrences were observed in only 4.

ITALY

Problems of Oncology.—At the May meeting of the Lombardy Society of Medical and Biological Sciences in Milan, Professor Natale of the Milan Tumor Institute said that of 71 patients in whom hysteroadnexectomies were performed according to Wertheim's method with systematic lymphadenectomy, lymphatic metastases were found in 17% of those in whom the disease was in the first stage and in 33.3% of those in whom the disease was in the second stage. They were observed, however, only in those in whom the operation was performed two months after the completion of radium therapy and never in those who had not received such therapy. He questions, therefore, whether radium therapy should be advised for women with uterine cancer in early stages. Professor Grattarola of the Cancer Institute of Milan discussed the persistence of the ovarian activity after radium therapy for carcinoma of the uterine cervix. By giving the patients treated with radium appropriate doses of gonadotrophins, he caused persistent vasomotor phenomena to disappear and produced a eutrophic change in the vaginal epithelium and a follicular proliferation, followed by luteinization, in the ovary.

Dr. Bianco, who is also from the Cancer Institute, reported on eight patients with theca cell tumor, which in two was associated with cancer of the endometrium. He emphasized the possibility of a histological differential diagnosis of these tumors from fibromas without histochemical investigations. The nuclei of the cells of these tumors are thicker and bigger and have nucleoli that are more voluminous and more evident than is the case in the nuclei of the cells of fibromas. Professor Sirtori said that the cytological search for neoplastic elements of bronchial origin gives a greater percentage of correct diagnoses when the investigation is made on material secured by expectoration than on that obtained by aspiration of the bronchi. In his studies on the sputum of 36 patients with cancer of the lung, the cytological examination gave positive results in 32 instances, whereas in studies on the material aspirated from the bronchi of 49 patients with cancer of the lung, the cytological examination gave positive results in only 34. The main disadvantages to the use of material secured by bronchial aspiration are that the bronchoscope may not be inserted into the bronchus affected by the tumor and that bronchoscopy may be performed after the tumor cells that were present in the bronchial lumen have been discharged by the patient. On the other hand, all the tumor cells that scale from the neoplasm are gathered and preserved in the sputum and can easily be detected, even if the material is collected on two or three consecutive mornings, as long as it is placed directly into a container with denatured alcohol and if, with this material, histological specimens in paraffin are prepared.

Law of the Heart.—At the June meeting of the Filippo Pacini Medical Academy of Pistoia, Professor Maestrini of Arezzo said that in 1914 he defined the law of the heart as follows: "The heart is capable of performing a greater amount of work when its fiber is lengthened." The new diagnostic means such as cardiac catheterization, angiocardiography, kymography, and the new techniques for operations on the lung and the heart indicate that the heart follows this law any time it has to perform a greater amount of work. In other words, whenever the heart meets with propulsive difficulties, it increases its systolic residuum, becomes dilated, and becomes capable, by means of this dilatation, of increasing its systolic energy and of overcoming, at least in part, the obstacles that block the free passage of the blood. In the clinical field the law of the heart has helped to identify a new means of cardiac compensation (dilatory compensation) and to clarify in the simplest and easiest of ways the origin of cardiac hypertrophy.

SWEDEN

BCG Vaccination.—Since the voluntary BCG vaccination of school children in Stockholm was started in 1943, about 50,000 have been so treated. In 1941 there were 23 deaths from tuberculosis among Stockholm's children, aged 0-15, whereas there was not one such death in the same age group in 1952. In the same period tuberculosis morbidity among school children dropped from 3.9 to 0.7 per 1,000. Reviewing these and other findings in the quarterly journal of the Swedish National Association against Tuberculosis, Dr. Herbert Enell gives BCG vaccination some of the credit for these figures in view of the fact that a comparison of tuberculosis morbidity among the vaccinated and nonvaccinated is greatly in favor of the former. Thus, of 3,112 children successfully vaccinated, only 7 developed tuberculosis, and then always in a mild form (a rate of only 0.5 to 1 per 1,000 yearly), whereas among 843 not vaccinated with BCG, 328 developed tuberculosis (a rate of 10 to 40 per 1,000 yearly).

Grouping the school childrens' homes in three different social classes, Enell concluded that the parents' decision for or against vaccination was not influenced by their position in the social scale. With regard to the frequency with which BCG vaccination should be repeated, he has found that 91.6% of the children vaccinated at the ages of 7 and 8 were still tuberculin-positive nine years later. He suggests that this vaccination be given at birth, on entering school or leaving school, and on commencing military service.

In *Svenska läkartidningen* for Sept. 9, 1955, Dr. Erik Jacobsson compared subcutaneous and intracutaneous injections of BCG. Giving the same preparation of BCG by subcutaneous injection in 382 and by intracutaneous injection in 278 subjects, he found that the incidence of necroses at the site of the injection was much greater after the subcutaneous than after the intracutaneous injections. Subsequent testing of both groups with tuberculin showed little difference in the reactions to it.

Appendectomy at Gynecologic Operations.—The routine practice of removing the appendix in the course of gynecologic operations was shown to be fully justified by an investigation of 523 gynecologic operations reported by Angervall and Hesselsjö in *Nordisk medicin* for July 21, 1955. The authors excluded from their study patients in whom there were clinical signs of appendicitis at the time of the gynecologic operation. The removed appendixes were subjected to Weigert-Hansen staining, supplemented in most cases by hematoxylin-eosin staining for the determination of eosinophilia. Pathological changes were found in 60%. In 38 cases (7.3%) histological changes indicative of acute appendicitis were found; the largest pathological group consisted of 117 cases (22.4%) showing fibrous obliteration of the lumen of the appendix; in 24 cases (4.3%) eggs of Enterobius vermicularis were found in the lumen of the appendix without any concomitant sign of appendicitis; in the 3 cases in which the appendix was found to be the seat of cancer, the primary new growth was situated in the uterus or ovary; and in one case there were tuberculous changes in the appendix. As the appendectomy had no deleterious effect on the postoperative course of any of these patients, this investigation gives full support to the practice of removing the appendix whenever a surgeon finds it convenient.

Medical Jubilee.—Sweden created a medical service in 1688, and its members were required not only to act as general practitioners but also as health officers with administrative responsibilities. In this dual capacity many a physician had occasion to complain that the state was a niggardly employer. After nearly two centuries of experience with the state as an employer, the members of this service banded together in July, 1880, to form an association to further the material interests of its members. In August this association celebrated the 75th anniversary of its founding. At present, there are about 350 appointments in this service, with a senior member for each county. The senior member is responsible for the health of his county and supervises the activities of his subordinates and those of the pharmacists in his district. Recruiting for this service has encountered difficulties due in part to the rival offers of other services. The physician who becomes a health officer in the far north of Sweden may not be in so enviable a position as his colleague who works in a hospital with a well-equipped laboratory.

URUGUAY

Poliomyelitis.—At a meeting of the National Academy of Medicine, Perez and his co-workers reported studies of serum from subjects aged 8 months to 20 years. They found that 95% of subjects examined had antibodies against at least one type of poliomyelitis virus. At the age of 4 years, 72% of the urban population was found to have antibodies against at least one type of virus. Natural immunity is developed earlier and more completely in those living in the country than in those living in the city. The type 3 virus is most prevalent in Uruguay. Among the urban children, those visiting the country in the summer develop a higher immunity than those visiting the seaside.

CORRESPONDENCE

MEDICOLEGAL OFFICE

To the Editor:—From a study of case material passing through the coroner's office of the county and city of San Francisco, Dr. Turkel in THE JOURNAL, Aug. 27, 1955, page 1485, concluded that "the ultimate in scientific accuracy and in the discharge of responsibility to the public" by the office of coroner or medical examiner requires that office to perform autopsies in between 23 and 25% of all deaths occurring in its jurisdiction. By so doing, an official medicolegal autopsy would be performed in every death known or suspected to have resulted from violence, as well as in every death that has occurred unexpectedly from unexplained causes. It would undoubtedly be desirable to secure the kind of factual evidence in all deaths from unexplained or presumably violent causes that can only be obtained by autopsy. For that matter, it would be desirable from the standpoint of preventive medicine, medical research, and medical education to have such information about all deaths, regardless of the clinical impressions of their causation. In some jurisdictions, such as the city and county of San Francisco, public policy apparently condones by statute and supports by the allocation of public funds the performance of compulsory autopsies in virtually all deaths due to violent or unknown causes. Not all cities and counties are so enlightened and prosperous, nor do all cities and counties have a sufficient number of medicolegally trained pathologists to carry this large volume of medicolegal autopsies. In these latter communities, and they probably constitute a substantial portion of the total in the United States, it is necessary to take steps to achieve a reasonably satisfactory improvement rather than "the ultimate" in this branch of government. It is believed by many experienced medicolegal pathologists that the interests of justice and public safety require compulsory official autopsies in approximately 25% of all deaths referred to the office of the average coroner or medical examiner. This would comprise about 5% of all deaths. Beyond this figure it is felt that the law of diminishing return operates and that the cost per case mounts rapidly for the discovery at autopsy of each previously unsuspected murder or hazard to public health. If the cost of medicolegal examinations is to be held at a level that will insure the acquisition of such facts as are necessary to prevent the criminal prosecution of any citizen because of inadequate or incompetent medical evidence, and will insure that relatively few murders or previously unsuspected hazards to public health will pass unrecognized, the funds allocated to the office of coroner or medical examiner should be sufficient to employ expert pathologists to perform autopsies in at least 25% of all violent or unexplained deaths.

Cleveland 6.

To the Editor:—It was gratifying to notice that the lead article in the Aug. 27, 1955, issue of THE JOURNAL was devoted to forensic medicine. I read the article by Dr. Henry W. Turkel, "Evaluating a Medicolegal Office," with a great deal of interest. Noteworthy is the first sentence in which is stated: "There is wide and general agreement that 20 to 25% of all deaths require medicolegal investigation." Dr. Turkel continues by defining an "autopsy index," which is:

$$\frac{\text{“no. of medicolegal autopsies}}{\text{total deaths in the community}} \times 100\text{”}$$

In his article he states further that the autopsy index in states with adequate statutory provisions should range between 20.7 and 25. In other words, he advocates an autopsy in every coroner's or medical examiner's case although he cited various medicolegal authorities who feel that, in general, 20% of all cases coming into a medicolegal officer's jurisdiction require autopsies. This is greatly different from 100%. While autopsies in as many as 50% of all medicolegal cases, as defined by Dr. Turkel, may be desirable in urban areas with a large transient population, such as New York City, there is no reason to believe this is necessary or desirable for the country as a whole. There are many instances where a complete autopsy would yield little evidence of medicolegal importance that could not be determined from a careful examination of witnesses, the scene of death, and external examination of the body. Such evidence would almost certainly stand up in most courts. It is well recognized that a coronary occlusion may be the proximate cause of an automobile accident, but why perform an autopsy on the passengers? An occasional victim of suicide may be suffering from organic brain disease. But is it in the public's interest to go to the expense of performing autopsies in all cases of suicidal death, especially when the fact of suicide is well documented with an obvious cause of death and a bona fide suicide note? It is also difficult to understand that an autopsy on an 85-year-old patient who died in a hospital with a well-established cause of death several weeks after falling and breaking a hip would produce sufficient additional evidence of medicolegal importance to justify the expense to the government. Certainly a postmortem blood sample or spinal fluid sample should usually be obtained for analysis for alcohol. These should be obtained in all medicolegal cases except in the very young. I do not mean to belittle the importance of performing autopsies in all cases where there exists a possibility of criminal liability of another, where trauma of unknown origin exists, where there was no known medical attention recently, or where there were no competent witnesses to the death and the attending physician is unable to ascribe a known cause. In such cases an autopsy is mandatory, of course. It is my experience, however, that many highway fatalities and true suicides, and some sudden and unexpected deaths from natural causes do not require an autopsy. In these cases the cause of death can be ascribed with reasonable accuracy. However, I may not be so much at variance with Dr. Turkel as this may appear depending on our definitions of an autopsy. By autopsy I mean a complete investigation of the head, thorax, abdomen, and other regions as the circumstances may require. To my mind, an autopsy is not merely an examination of the external appearance of the body, nor minor procedures such as obtaining a sample of a body fluid for chemical analysis. I doubt the public benefits significantly from increasing the autopsy rate from between 20 and roughly 50% of all medicolegal cases, as exists in such areas as New York City, New Orleans, Baltimore, Cleveland, and the state of Vermont, to 100% as Dr. Turkel suggests. This would cause the expenditure of a great deal more public funds although from a scientific viewpoint there is no doubt that something can be learned from all autopsies.

THE CANCER PATIENT

To the Editor:—I have read many articles on whether to inform a patient he has cancer, but most seem to miss the point. In my opinion the patient with a possibly curable cancer should almost always be told in order to make him understand the reason for treatment, which often causes considerable discomfort. No one knows how he will react to a given situation beforehand. Conclusions based on questionnaires inquiring how one would wish to behave under a hypothetical situation are not valid. The only real problem is in the situation where the malignant disease is hopeless. I have almost always found that if I wait the patient will never ask me "Do I have a cancer?" If he does, I answer him honestly, but most of these people have a good idea of what is causing their illness and do not wish to have us close the door.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Aortic Stenosis: A Clinical Study. M. B. Matthews, W. E. Medd and R. Gorlin. Brit. M. J. 2:759-763 (Sept. 24) 1955 [London, England].

The authors report on 50 patients, between the ages of 9 and 76 years, with aortic stenosis. There were 31 males and 19 females. The condition was congenital in 6, rheumatic in 20, and of undetermined origin in 24. The incidence of rheumatism was greater in the female than in the male patients. Twenty-one of those with aortic stenosis of undetermined origin were men. Enlargement of the left ventricle was revealed by fluoroscopy in 44. The brachial arterial pressure pulse was recorded in 39 patients; the measurement of the systolic upstroke time from the end of the diastole to the final sustained peak of the systole was greater than 0.15 second in 37 patients. One of the remaining two patients had minimal stenosis, while no explanation was found for the normal upstroke time in the other. In the presence of the characteristic harsh systolic murmur, maximal either in the aortic area or in the suprasternal notch, the severity of the stenosis was established by evidence of the left ventricular hypertrophy, and it was supported by a systolic upstroke of more than 0.15 second in the brachial arterial pressure tracing. The critical aortic valve area appears to be of the order of 0.5 sq. cm. in isolated aortic stenosis and is variably larger when there is coexisting aortic incompetence. Comparison of the natural history of aortic stenosis with that of mitral stenosis shows that in the former there is a long symptomless period and, when left ventricular failure occurs, a short period of severe symptoms until death, but at any moment sudden death may occur. In the latter there is a comparatively long period of severe symptoms and the downhill progress is marked by exacerbations that are often associated with attacks of bronchitis, with pulmonary infarction, or with pregnancy. The problem of selection of patients for valvulotomy is more difficult than in mitral stenosis, since severe aortic stenosis is often compatible with an active life, and when left ventricular failure eventually occurs the valve may well be so abnormal as to prohibit an effective valvulotomy. At present, the operative mortality is high and the long-term results are unknown.

New Antidiabetic Principle: Results of Clinical Studies. H. Franke and J. Fuchs. Deutsche med. Wchnschr. 80:1449-1452 (Oct. 7) 1955 (In German) [Stuttgart, Germany].

A new sulfonamide preparation N_1-sulfanilyl-N_2-n-butylcarbamide (BZ 55) was given a trial in healthy persons in whom it caused pronounced fatigue, sweating, sensation of hunger, tremor, and a certain euphoria. Blood sugar determination showed definite hypoglycemic effects. The drug then was given to 50 patients with diabetes mellitus. In diabetics who were not treated with insulin, delayed depression of the blood sugar level resulting from the administration of BZ 55 caused considerable reduction or complete subsidence of glycosuria. As a rule, the same results were obtained in diabetic patients treated with insulin. BZ 55 failed in diabetic patients who did not show an easy response to insulin or in those in whom diabetes mellitus was made worse by associated febrile diseases such as pulmonary tuberculosis. With a diabetic diet, or even with an unrestricted diet, it was possible to discontinue the administration of insulin entirely or partly. The authors believe that the effect exerted by BZ 55 depends on the blockade of the A-cells of the pancreas causing a preponderance of the homorganic insulin in the B-cells. Apparently one does not deal with a toxic side-effect of the drug but with an improvement in the disturbed metabolism. Initial large doses of BZ 55, i. e., 1 gm. three times daily for several days, should be given orally; treatment may then be continued with a maintenance dose of 1 to 1.5 gm. daily. Undesirable side-effects were not observed with these doses.

An Effective Peroral Antidiabetic Drug (BZ 55). F. Bertram, E. Bendfeldt and H. Otto. Deutsche med. Wchnschr. 80:1455-1460 (Oct. 7) 1955 (In German) [Stuttgart, Germany].

N_1-sulfanilyl-N_2-n-butylcarbamide (BZ 55) was given a therapeutic trial in 82 patients with diabetes mellitus varying in degree of severity and in duration. The drug was administered in tablets of 0.5 gm. and, because of the delayed onset of its hypoglycemic effects, 5 tablets were given on the first day of treatment, 3 tablets on the second day, and 2 tablets on successive days, and this at first without consideration of the duration and severity of the diabetes mellitus, the patient's body weight, and the conditions of absorption. A therapeutically effective blood sugar level was obtained with these doses in most of the patients. In 28 diabetic patients between the ages of 49 and 77 years, who had been treated exclusively by dietetic measures, constant glycosuria of more than 100 gm. per day subsided completely within a few days of treatment, and simultaneously there occurred a rapid depression of the fasting blood sugar level of from 300 mg. per 100 cc. to below 150 mg. per 100 cc., as well as a definite lowering of the daily profile with maximal values below 200 mg. per 100 cc. After a 10-day course of treatment, it was possible to discontinue the administration of the drug in several patients on a strict diet whose metabolism remained balanced for four months of follow-up. Three patients with mild acidosis without signs of precoma were treated with high doses of BZ 55 up to 5 gm. daily for several days, but without effect on the high blood sugar level, the high glycosuria, or the acetonuria. In 38 diabetic patients between the ages of 41 and 77 years who had been treated with insulin in doses up to 88 units daily, administration of this drug was discontinued abruptly and administration of BZ 55 was instituted with the previously mentioned schedule, and occasionally with 5 tablets on the first day and 3 tablets not only on the second but also on successive days. In 28 of the 38 patients, BZ 55 proved to be a complete substitute for insulin, although the metabolism occasionally became unbalanced temporarily in the course of the first days of the treatment; in the remaining 10 patients decompensation occurred, sometimes immediately and sometimes after one to two weeks, requiring reinstitution of insulin therapy. In 10 diabetic patients between the ages of 15 and 40 years, BZ 55 was ineffective. Tolerance of the drug was good without exception. There were no undesirable side-effects, except for a definite sulfonamide dermatitis in three patients in the course of the first three days of the treatment and a generalized pruritic rash on the 12th, 13th, and 20th days after the start of the treatment in three other patients. As a result of their experiences, the authors feel justified to state that BZ 55 is the first antidiabetic drug that is definitely effective when given orally. Exact dietetic measures are as indispensable to the use of this drug as to that of insulin. Further experiences are required regarding mechanism of action, width of indications, optimum dosage, and possible side-effects. Routine use of BZ 55 must be postponed until the results of extensive trials now in progress at several clinics are known.

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1946 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

A Concept of Diabetes. W. P. U. Jackson. Lancet **2**:625-631 (Sept. 24) 1955 [London, England].

Jackson shows that, apart from the clinically obvious glycosuria, ketosis, and hyperglycemia, diabetes is an innate obscure disorder of carbohydrate metabolism, which manifests itself in curious diverse ways such as in the hypertrophied islets of overweight stillborn babies, in microaneurysms in the retina, in cardiac infarction in the female, and in excessive tallness in the child and obesity in the mother. The cause of diabetes is not known nor is its real relation to growth and size understood, but apparently diabetes in the latent form ("pre-diabetes") remains with the victim years or decades before he or she becomes overtly diabetic. During this time, pregnancy, corticotropin therapy, acquisition of adrenal cortical hyperfunction (Cushing's syndrome) or of acromegaly, a micrococcic (staphylococcic) infection, or overeating may uncover the individual already predisposed to diabetes. The previously adequately compensating pancreas cannot stand the additional stress completely, and evidence of the latent diabetic state is brought to the surface, divulging its menacing presence by embryopathies or changes in carbohydrate tolerance. Hence it is wrong to talk of diabetes only when glycosuria and hypercalcemia are present. It is a disorder that goes back much further than that—even into the womb. Pregnancy is a dangerous stress to the pancreas. That it is diabetogenic to the mother is evident from the worsening of the hyperglycemia and the retinopathy during pregnancy in a woman with established diabetes; from the appearance of retinopathy for the first time during pregnancy, and its disappearance after parturition; from the occasional appearance of hyperglycemia and glycosuria in a nondiabetic, which disappears after parturition; from the hypertrophied pregnancy pancreas; from the rarity of diabetes in the post menopausal woman who is childless; and from the potentiation of the diabetogenic effect of cortisone and alloxan in laboratory animals. That pregnancy is diabetogenic also to the fetus is demonstrated by the fact that the infant of the diabetic mother is often stillborn, oversize, and overweight. Such a baby is also red, fat, flabby, edematous, and weak. It respires with difficulty and has hepatomegaly, cardiac hypertrophy, erythroblastosis, and hyperplasia of the islets of Langerhans. The abnormal internal uterine environment of the prediabetic woman may also produce either a stillbirth, due to excessive size and other defects, or a child who grows too tall and has an abnormal vascular system and a tendency to the development of diabetes. With regard to the recognition of the prediabetic woman, the author says that, starting with a very large baby or an unexplained stillbirth, it is often possible to detect whether prediabetes in the mother was the cause by testing the glucose tolerance of mothers after childbirth. There is considerable evidence that children, before becoming diabetic, grow excessively in both size and weight. The author also comments on diabetes and obesity in middle age, the role of the growth hormone, of insulin, and of the glucocorticoids.

SURGERY

Congenital Aneurysm of the Right Aortic Sinus Associated with Coarctation of the Aorta and Subacute Bacterial Endocarditis: Ante-Mortem Report of a Case. I. Steinberg and N. Finby. New England J. Med. **253**:549-552 (Sept. 29) 1955 [Boston].

The occurrence of an unruptured aneurysm of the right aortic sinus in the presence of subacute bacterial endocarditis, aortic regurgitation, and coarctation is described in a 27-year-old woman who was admitted to the New York Hospital in New York City, because of congenital heart disease that had been discovered shortly after birth. For the first 12 years she was well. At the age of 20 the patient had subacute bacterial endocarditis and was treated successfully with penicillin for two weeks. Nine months before her admission to the New York Hospital she had a second attack of subacute bacterial endocarditis and was treated at another hospital with penicillin and streptomycin for seven weeks. When she was first admitted to the New York Hospital, roentgenograms of the chest were made and angiograms in the left anterior oblique view were taken that showed marked hypertrophy of the left ventricle, coarctation of the aorta, prominent collateral arterial branches, and a saccular aneurysm of the right aortic sinus, measuring 2.2 cm. in diameter. Because of fever and persistent moderate leukocytosis, the patient was treated with large doses of penicillin for two weeks and discharged to her home, where she continued to notice easy fatigability and had dyspnea with moderate exertion. Two months later she was digitalized because of episodes of nocturnal dyspnea, and this early sign of heart failure warranted her readmittance to the hospital for surgical treatment. With the aid of hypothermia, the coarcted segment of the thoracic aorta was excised and an end-to-end anastomosis was made with the aid of a Pott clamp. The pulsatile aneurysm was seen and palpated; its size conformed to that shown by the angiocardiogram. Repair of the aneurysm did not appear advisable because of the presence of severe aortic regurgitation. The systolic murmur along the left sternal border, which had been heard preoperatively, disappeared after the operation. There was postoperative lowering of systolic blood pressure and increased blood pressure in the legs. Three months after the operation, the patient felt well and her exercise tolerance was improved. Although not enough time has elapsed for proper evaluation of the result, the authors' case, which was diagnosed during life, suggests that, in uncomplicated cases, particularly before rupture compromises the heart, surgical treatment is feasible through the right cardiac chambers.

The Results of Direct Vision Closure of Ventricular Septal Defects in Eight Patients by Means of Controlled Cross Circulation. C. W. Lillehei, M. Cohen, H. E. Warden and others. Surg. Gynec. & Obst. **101**:447-466 (Oct.) 1955 [Chicago].

The authors describe the techniques utilized and the observations made on the first eight patients in whom ventricular septal defects were closed by open cardiotomy utilizing total bypass of the heart. Controlled cross circulation provides a reliable method for excluding the heart and the lungs from the circulation for prolonged periods. It consists of the simultaneous reciprocal exchange of equal quantities of compatible blood from the arterial system of the donor to the patient's arterial circulation and from the caval system of the patient to the veins of the donor. The donor's circulation has to oxygenate and revitalize the venous blood received from the patient. A pump is essential to control accurately this continuous interchange of blood between patient and donor. Technical factors in the clinical application of cross circulation are described in detail, with particular reference to the cannulation, anesthesia, and selection of compatible donors. Eight patients, all of whom were seriously ill with ventricular septal defects, cardiomegaly, and pulmonary hypertension, had their circulatory systems linked with a suitable donor, their hearts and lungs totally bypassed, and a right ventricular cardiotomy carried out to permit direct vision suture of their ventricular septal defects. All operations were carried out at normal body temperatures. The hearts and lungs of these eight patients were totally bypassed for from 5 to 26½ minutes, during which time the patient's body was perfused at reduced rates of flow based upon the azygos flow experimental studies. These reduced rates of flow have been demonstrated to be safe. There were two deaths in these first eight patients. Both involved infants, occurred 4 and 11 days after operation, and were caused by respiratory complications, to which these patients are particularly susceptible. Disturbances of the conduction systems, such as ventricular fibrillation or persistent complete heart block, did not occur, although all defects were closed by direct sutures placed in the ventricular septum with no effort being made to avoid the so-called vulnerable areas. Experimental observations indicating that the heart, euthermic and totally bypassed, needs only a very reduced coronary arterial flow to remain well oxygenated were verified in man. Furthermore, such a heart becomes very resistant to arrhythmias. Such possible complications as air embolism, excessive hemolysis, or postoperative hemorrhage have been completely absent. Recatheterization of four of the six surviving patients from four to nine months after operation revealed that the septal defect was completely closed and that no shunt remained. In two of these patients, the pulmonary pressure has returned to normal. The four patients represent the first to receive complete correction of ventricular septal defects, with disappearance of murmurs and thrills and closure of the shunt.

Survival After Lung Resection for Bronchial Carcinoma. J. R. Bignall and A. J. Moon. Thorax **10**:183-190 (Sept.) 1955 [London, England].

Bignall and Moon studied the duration of life after lung resection for bronchial carcinoma and the effects of various factors on survival in a group of 531 patients treated at hospitals for diseases of the chest between 1940 and 1951. Four hundred fifty-three survived the early postoperative period. Their chance of surviving one year was 63%, two years 47%, and five years 33%. The two and five year rates for those reported to have squamous tumors was 52% and 36%, compared with 34% and 26% for those with undifferentiated growths. The apparent involvement of the mediastinal nodes at operation had a considerable influence on the survival. The two and five year rates for those without enlarged nodes were 61% and 48%, but for those with enlarged nodes the rates were only 27% and 11%. The prognosis appeared to depend to some extent on the location of the tumor. The highest survival rates were observed with cancers of the right upper lobe, the two year rate being 57%; the left upper and right lower lobes had similar though slightly lower rates, but the two year rate with cancers of the left lower lobe was significantly lower, being only 36%. No regular pattern of survival in relation to age was detected. The prognosis was better in women than in men. The survival rates were lower in those with symptoms for six to eight months than in those with either shorter or longer histories. The differences in survival rates after pneumonectomy and lobectomy could be largely attributed to the smaller proportion with involved mediastinal nodes among those having a lobectomy. The operative mortality decreased from 19% between 1940 and 1946 to 10% in 1950 and 1951.

NEUROLOGY & PSYCHIATRY

The Probable Influence of Salk Poliomyelitis Vaccine on Reported Poliomyelitis in North Carolina. B. G. Greenberg and C. M. Cameron Jr. North Carolina M. J. **16**:391-395 (Sept.) 1955 [Winston-Salem, N. C.].

From the official records of poliomyelitis reports in the files of the division of epidemiology of the North Carolina State Board of Health during the five-year period of 1950 to 1954, an attempt was made by the authors to predict, within certain limits, the total number of reported paralytic and nonparalytic cases of poliomyelitis that might be expected in the state. In an average year, there will occur in North Carolina a total of 630 reported cases of poliomyelitis of all types. Of these 630 cases, 350 are expected to manifest some degree of paralysis. In a low incidence year, one may expect 409 cases of all types, of which 226 will be paralytic. In the course of a high incidence year, 987 cases are predicted, of which 551 will be paralytic. From the report of Dr. Thomas Francis of the University of Michigan on the 1954 field trial of the Salk vaccine, the authors attempted to predict what influence the use of the vaccine will have on the abovementioned anticipated incidence of poliomyelitis. The 630 cases of all types that might be expected in the average year would be reduced to 321 if every person in the state received a complete immunization with the Salk vaccine and the effectiveness were the same in all age groups of those studied in the 1954 field trial. In like manner, the 350 paralytic cases that are anticipated in the course of the average year could be reduced to 98 if 100% of the population were successfully inoculated. These estimates are based on the Francis report findings that the vaccine is 49% effective against all types of poliomyelitis, not effective against nonparalytic poliomyelitis, and 72% effective against paralytic poliomyelitis. The use of Salk vaccine among all first and second grade school children only would reduce the 630 cases of all types of poliomyelitis expected in the average year to 576, the high figure of 987 to 914, and the low figure of 409 to 368. The 54 cases of paralytic poliomyelitis expected in these age groups in an average year could be reduced as low as 15 if every first and second grader received the vaccine. Therefore, this would reduce the total number of paralytic cases expected in the average year from 350 to 311. A recent survey by the North Carolina State Board of Health showed that less than half the counties in the state plan to offer second inoculations before the opening of school, and early reports from counties offering vaccine indicate that from one-fourth to one-third of the eligible children have responded to the invitation to a second dose of vaccine. The authors conclude that there is every reason to believe that the use of the Salk vaccine among some first and second grade school children will have little influence on the poliomyelitis rates recorded in the state of North Carolina in 1955. It may be suggested that even widespread inoculations among hundreds of thousands of residents of North Carolina may have no statistical impact on the disease for several years to come.

Acute Poliomyelitis in Infants Under One Year of Age: Epidemiological and Clinical Features. H. Abramson and M. Greenberg. Pediatrics **16**:478-488 (Oct.) 1955 [Springfield, Ill.].

Of a total number of 3,510 cases of poliomyelitis that occurred in New York City in the course of 1949 and 1950, 92 occurred in infants less than one year old, of whom 52 were boys and 40 were girls. Comparison of the epidemiological and clinical features of poliomyelitis in these infants with those in children and adults revealed that clinically recognizable poliomyelitis was of infrequent occurrence among infants less than one year old. It was even more infrequent among infants in the first six months of life. This is in marked contrast to the findings in the 1950 epidemic in Israel, where one-third of all cases occurred in the first year of life and one-tenth in infants in the first half year of life. Infant boys exhibited a greater susceptibility to the disease than girls. Eight of the 92 infants died, a high mortality rate of 8.7%; fatalities were particularly high among infants less than 3 months old, with some predominance of deaths in boys. Nonparalytic forms of poliomyelitis occurred infrequently among the infants less than one year old, especially in the first six months of life. Paralytic forms of the disease were dominant, spinal involvement being more common than bulbar. Deaths occurred chiefly in infants with the bulbar form of poliomyelitis, as in older children and adults. The mortality rate was higher in infants than in older children and higher than in patients of all ages combined. The onset of poliomyelitis among infants less than one year old was variable; it was acute, with fever, fever with nuchal spasm, or the triad of fever, nuchal spasm, and spasm of back muscles. Temperature at the onset of illness averaged 98.3 F (36.8 C), with a low of 97.6 F (36.3 C) and a high of 102 F (38.8 C); subsequent temperatures were higher, the mean being 102.8 F (39.3 C). The interval between onset of illness and first detection of paralysis averaged 5.5 days, with a spread from the day of onset to 25 days later. Paralysis of a single limb occurred more frequently than of two or more limbs, and the ratio of arm to leg paralysis was about 1 to 3. Initial spinal punctures in infants less than one year old were made on an average of 3.4 days after the onset of the disease in nonparalytic cases, and 5.7 days in paralytic cases. The spinal fluid was usually clear, with a mean count of 91 lymphocytes per cubic millimeter. The average sugar content was 55 mg. per 100 cc. of fluid, and protein, 72 mg. per 100 cc. of fluid.

PEDIATRICS

Mumps Encephalitis: Pathology and Pathogenesis. W. L. Donohue, F. D. Playfair and L. Whitaker. J. Pediat. **47**:395-412 (Oct.) 1955 [St. Louis].

The characteristic central nervous system lesion found in two cases of fatal mumps encephalitis was an acute perivascular demyelinization similar to that seen in the other postinfectious encephalitides. Reports in the literature of mumps encephalitis with a fatal termination are few, and even fewer are the cases in which a histological study of the nervous system has been made post mortem. A case previously reported by one of the authors (W. L. D.) in 1941 and another observed in 1954 are therefore presented together. The first of the authors' patients was a 5-year-old girl who died three days after admission to the Hospital for Sick Children, Toronto, Canada; the second was a 14-year-old boy who died suddenly two days after he was admitted in coma to St. Catharines General Hospital. The lesions in these two cases were essentially the same and were similar to those described in the few unequivocal cases contained in the literature. The incidence of neurological complications in mumps cannot be accurately estimated, because mumps is largely a benign disease of childhood treated at home and data for all the home cases are not available. Clinical involvement of the nervous system, however, is not rare and may be manifested in a variety of ways. The most familiar of these is the so-called meningitis or meningoencephalitis, which is characterized by an increase of cellular elements, chiefly lymphocytes, in the cerebrospinal fluid. This pleocytosis of the cerebrospinal fluid may or may not be accompanied by symptoms and signs of encephalitis or meningeal irritation. The mumps virus is also responsible for a significant number of cases of so-called "acute aseptic meningitis," in which there is no clinical evidence of parotid, testicular, or visceral involvement. These may be confused with nonparalytic poliomyelitis. Myelitis, polyneuritis, and neuritis limited to one or more nerves have occasionally been reported and may cause permanent damage; usually, however, the paresis or paralysis is transient and recovery is complete. Evidence is accumulating to support the belief that mumps encephalitis is caused by the mumps virus itself, probably as a result of either an augmentation or enhancement of its neurotropic properties or a particular susceptibility of the nervous tissue in certain persons.

Tay-Sachs Disease in two Sinhalese Children. C. C. de Silva and G. E. Tennekoon. Brit. M. J. **2**:768-770 (Sept. 24) 1955 [London, England].

Two cases of cerebromacular degeneration of Tay-Sachs type are described in Sinhalese boys, aged 2½ and 2 years when admitted to the Children's Hospital in Colombo, Ceylon. The children showed mental retardation, myoclonic fits, blindness with a dark purple patch at the fovea centralis surrounded by a white halo of avascular degenerated tissue, and primary optic atrophy. In one patient, the disease started at 2 months of age and the duration of the disease was two years and eight months; in the other patient, the disease started at the age of 2 years and its duration was only two months. Autopsy was performed in both cases and microscopic examination of the brain revealed swollen ganglion cells with a foamy cytoplasm and a small nucleus, which had been described previously by other workers. The only unusual feature in one case was the presence of large hyaline masses undergoing calcification in some parts of the brain substance and in the piarachnoid. The nature of these changes is unknown. The infantile type of Tay-Sachs disease has been described by other workers in Swiss and Norwegian children, and there is no longer any reason to state that Tay-Sachs disease arises almost exclusively in Jewish infants.

Contribution to the Study of the Immune Response Following Antidiphtheritic Vaccination by the Percutaneous Route. G. Santopadre and L. Poli. Clin. pediat. **37**:483-490 (July) 1955 (In Italian) [Bologna, Italy].

Results of experiments on rabbits indicated that it was possible to obtain a state of antitoxic immunity against diphtheria by applying pads of adhesive plaster containing diphtheria anatoxin in a dose equal to 50 Lf to the shaved back of the animals. The application of similar pads containing more anatoxin (100 Lf) to the unbroken skin (patch vaccination) of 10 children who had never been vaccinated against diphtheria had no effect. The same studies on 16 children, who had been vaccinated three to six years earlier and in whom the reaction to Schick's test was markedly positive, revealed that the reaction had become negative in all of them and that the serum antitoxin level was increased. Studies on 34 children, of whom only 23 had been vaccinated in the second year of life but in whom the reaction to Schick's test was positive, revealed that the patch vaccination had no effect in the 11 children who had never before been vaccinated and in 3 vaccinated children who had shown no acquired reactivity before the pads (three pads were applied at a 10 day interval) were applied. The reaction to Schick's test became negative only in those vaccinated children in whom a certain degree of acquired reactivity was present before the patch vaccination. The different behavior of the immune response of the rabbits and the children to the patch vaccination was probably due to the fact that the anatoxin dose was not sufficient to bypass in man the threshold limit essential to stimulate an immune movement in persons never before vaccinated and also to the fact that, despite all precautions taken, it was difficult to avoid the production of a solution of continuity in the skin of the rabbits while shaving them. The doses were sufficient, however, to reawaken and reestablish an immune process in those children in whom, because of a previous vaccination, there still was, even if only in the subliminal state, a certain degree of acquired reactivity. Thus, although this new method cannot replace the standard antidiphtheritic vaccination, it can be useful if it is used for the recall vaccination. In fact, the antidiphtheritic vaccination that the Italian laws make compulsory for all children in the second year of life confers an immunization that lasts for an average of two to three years. This immunization period can be prolonged if a new dose of vaccine (recall vaccination) is given in the following years. The authors suggest that this new method be used instead of recall injections, which are more painful and more disagreeable to the children.

UROLOGY

Adenocarcinoma of the Kidney. G. W. Briggs. Australian & New Zealand J. Surg. **25**:53-61 (Aug.) 1955 [Melbourne, Australia].

The 100 consecutive cases of carcinoma of the kidney presented were compiled from the records of several Melbourne hospitals. No case was included unless the diagnosis had been proved microscopically. A large number of cases with strong presumptive diagnoses were thus rejected. The triad of pain, hematuria, and mass was present in only 25 cases. The commonest single symptom was hematuria, this being present in 55 patients. In 17 instances, the hematuria was an isolated event before presentation at hospital, while 38 patients had experienced periodic episodes of blood in the urine. Pain was nearly as frequent as hematuria, being a feature in 52 cases. Loss of weight was a common symptom. In nine instances, the presenting symptom was due to a secondary manifestation In four of this group, there were bony metastases and in two, cerebral metastases. The presenting feature in one patient was a lump in the neck, while the last presented dyspnea due to pleural effusion. Thirty-seven patients were hospitalized without symptoms relating to the renal tract. A palpable abdominal mass was present in 16 of these patients, and, in 8, carcinoma of the kidney was correctly diagnosed. The diagnosis of abdominal carcinoma, primary site unknown, was made in five, and malignancy was not suspected in the three others. Malignancy was likewise not suspected in 11 of the 21 patients in whom no palpable mass was present. Thus, of the 37 patients with no renal history, 14 reached autopsy with no prior clinical suspicion of malignancy. Autopsy was done in 48 cases, and metastases were found in 35 of these. At autopsy, it was quite common to find a small tumor 1 to 3 cm. in diameter, but a tumor of this size was seldom seen at operation. Metastases are often present before nephrectomy is performed for an apparent local clinical lesion. The prognosis of the patient with this lesion is not improved by early surgical ablation. The malignancy of renal carcinoma is emphasized.

Subtotal Cystectomy in Treatment of Atony of the Bladder. F. J. Götzen. Ztschr. Urol. **48**:577-583 (no. 9) 1955 (In German) [Leipzig, Germany].

Götzen differentiates three forms of bladder atony: the neurogenic form, the decompensatory or mechanically induced form, and the myoneurogenic or congenital form. In the neurogenic form, in which all of the musculature controlling expulsion is atonic, even extensive resection of the mobile parts of the bladder will produce little improvement. Subtotal cystectomy is indicated chiefly in the myoneurogenic form of bladder atony and in patients in whom, after removal of the mechanical obstruction and prolonged bladder drainage, incomplete evacuation with a large amount of residual urine persists. The technique of subtotal cystectomy is comparatively simple. It was first suggested by

Orr in 1937 and subsequently has been used by a number of other urologic surgeons. Whereas some advise rigorous reduction of the size of the atonic bladder, others advocate a two-thirds resection. The author removes a little over half of the organ. After extraperitonealization of the bladder, its movable parts, the vertex and the lateral and anterior walls, are mobilized and pulled forward by means of a clamp attached to the vertex. Two lateral holding sutures at the level of the zone of resection facilitate the handling after the size of the organ has been reduced. Closure is done with the aid of a purse-string suture, and turn-in sutures, placed over it, further reduce the capacity of the bladder and secure the closure. The author used this method successfully in three patients. The subtotal resection improves the function of the bladder and greatly reduces the residual urine.

INDUSTRIAL MEDICINE

Pulmonary Disease in Relation to Metallic Oxides. K. M. A. Perry. Lancet **2**:463-468 (Sept. 3) 1955 [London, England].

If the oxides of metals are inhaled into the lung and remain in its lymphatics they will throw x-ray shadows, the density of which varies with the atomic weight of the metal. Some dusts are dissolved and are excreted by kidney or intestine, but others remain and cause shadowing. Though they may be inert and may not give rise to fibrosis, they may interfere with elasticity. Exposure to barium peroxide occurs in the manufacture of paints, fireworks, dyes, inks, depilatories, insecticides, rat poisons, glass, and linoleum and in the rubber industry. Exposure to the dust of barium peroxide in association with silica occurs during mining, and it produces the densest nodular lung shadows yet recorded. Pulmonary opacities have also been observed after the use of Pitressin snuff for diabetes insipidus, barium peroxide serving as the base for this snuff. Exposure to iron dust and fumes occurs in welders, oxyacetylene cutters, polishers, tool makers, cutlery makers, foundry workers, and hematite miners. The last two occupations involve exposure to iron dust and fumes associated with silica, and in consequence silicosis is a recognized risk in iron foundries and mines. A benign pneumoconiosis may develop in workers who inhale tin oxide dust. Although tin may be deposited in the lymphatics of the lungs, it does not give rise to fibrosis. Silver polishers use rouge that is iron oxide and are thus exposed to a dust consisting of a mixture of silver and iron. There is little doubt that part of the x-ray changes seen in these workers is caused by silver. The oxides of manganese, beryllium, vanadium, and osmium can all cause a chemical pneumonia. The sarcoid caused by beryllium is discussed in greater detail. Cadmium dioxide produces an unusual form of central emphysema, associated with impairment of respiratory function. While most workers in contact with aluminum dioxide dust have not been harmed by this exposure, severe pulmonary fibrosis, which caused some fatalities, has been reported in Germany and Canada, but these cases remain a mystery. Pulmonary carcinoma is observed in miners who have contact with arsenides. Thus diverse patterns of pulmonary disease may result from exposure to dust and fumes of metallic oxides. When the dust and fumes are extracted from the air in the factory and passed through chimneys into the atmosphere, the prevalence of pneumonia has been known to increase in the neighboring population; in people living near beryllium factories, sarcoidosis has been reported. Deaths in London after the dense fog on Dec. 8, 1952, have been attributed to acute bronchitis and its complications resulting from the inhalation of the dioxide and trioxide of sulfur extruded by factory and domestic chimneys.

Low Backache in Industry: Review of 1,163 Cases. R. N. Wilson and S. Wilson. Brit. M. J. **2**:649-652 (Sept. 10) 1955 [London, England].

Five years of experience at an ironworks with 1,163 men employed in heavy industry showed that suffering and absenteeism caused by low back pain can be greatly reduced if all cases, even trivial ones, are treated promptly by relaxation and manipulation. The methods used are admittedly empirical, but the uncertainty surrounding the exact causes of backache fully justifies the use of such methods, especially when they are effective. The patients' complaints vary from a dull low backache to acute stabbing pains in the back and/or buttock, groin, thigh, leg, and foot. Most patients are able to walk into the physiotherapy department, but a few are treated as stretcher cases by first-aid workers before being sent in. The routine treatment is begun by placing the patient in the prone position with a thin pillow under the hips and another at the head. This should give comfort even in the most acute attack. Infrared therapy is administered for 20 or 30 minutes, and the patient is encouraged to relax and to sleep if he wishes. Massage is then applied, beginning with light effleurage and gradually deepening into kneading. Full relaxation soon follows, and manipulation can then easily be performed if necessary, without anesthesia or sedation. The patient is advised concerning posture, especially when sitting, and the avoidance of incorrect lifting and of attempting to touch his toes; he is supplied with 6 codeine tablets to be taken two at a time during the next 24 hours, and he is encouraged to report again the next day if pain returns. This routine is most successful in acute attacks treated within 12 hours of onset. Injury to the sacrospinalis and other muscles, sometimes found in traumatic cases, may be treated with strapping as well as heat and massage, chiefly to give a feeling of support and to remind the patient to treat his back with care. No pressure is brought to bear on the men to remain at work, but most of them are advised to do so. Use of the term slipped disk, with its suggestions of operation and permanent transfer to less remunerative light work, is avoided for psychological reasons. A diagnosis of fibrositis, lumbago, sciatica, myalgia, or strained back or muscles, however, is acceptable, because almost everyone knows of someone who has had such a condition and has recovered completely. Simple urine tests and a straight x-ray film also have a psychological value. It is interesting to note that cold wet weather increases not only the pain of chronic backache, but also the actual number of traumatic cases. Furthermore, the first hour at work on a cold, wet morning is often the time when acute attacks occur. The loss to both employer and worker when an experienced man has to be permanently transferred to light work on account of backache is so great that every effort should be made to restore him to normal health as quickly as possible. The success of the method described, which represents an attempt by a general practitioner and a physiotherapist to deal with the problem of backache, is shown by the fact that in 1954 only 11 cases of back injury resulting in an absence from work of more than three days were reported to the factory inspector, out of a working population of 5,000; only five of these were traumatic in origin, although there were 122 traumatic cases in all.

THERAPEUTICS

Studies on the Metabolism of a New Salicylic Derivative: Ortho-Ethoxy-Benzamide (Etosalicil). F. Ducco, S. De Vercelli and R. Strobbia. Gazz. med. ital. **114**:93-99 (May) 1955 (In Italian) [Milan, Italy].

The authors report the results of studies on the metabolism of a new salicylic derivative, ortho-ethoxy-benzamide ("Etosalicil" or ethyl-salicylamide), which has the advantages over the other known salicylic derivatives of being less toxic, having a greater antirheumatic, antipyretic, and analgesic activity, and at the same time being better tolerated by the patients. They made their studies on the urine of two children with rheumatic infection who received the drug in daily doses of 3 and 4 gm., respectively, with good results and of a 29-year-old woman with rheumatic pyelosis, which developed after a mitral commissurotomy, who received the drug in daily doses of from 6 to 12 gm. orally plus 2 gm. in suppositories. The results indicated that the metabolism of the drug differs from that of salicylic acid and salicylamide. In fact, while most of the former is eliminated as such by the kidney and most of the latter is excreted as glucuronide and sulfuric ether or gentisates, about 50% of the new derivative is eliminated as soluble compounds of salicylamide (30%) and as ortho-ethoxy-benzoic acid (20%). The absence of carboxyls (acids) or free phenolic groups accounts for the complete absence of gastric disturbances during the administration of this drug and for its lesser toxicity.

BOOK REVIEWS

Cardiac Emergencies and Heart Failure: Prevention and Treatment. By Arthur M. Master, M.D., Cardiologist, Mount Sinai Hospital, New York, Marvin Moser, M.D., Assistant Physician in Medicine, Montefiore Hospital, New York, and Harry L. Jaffe, M.D., Assistant Attending Physician, Cardiology, Mount Sinai Hospital, New York. Second edition. Cloth. $3.75. Pp. 203, with 14 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1955.

In this second edition, the authors have included many of the newer drugs that have been used to treat cardiac emergencies. This is a well-written, impressive little volume which deals with practically all the emergencies encountered in the treatment of cardiovascular disease. While it does not pretend to be a textbook on cardiology, it does cover the cardiac emergencies thoroughly and specifically. The arrhythmias are well described, and the accepted methods of treatment are specifically outlined, including the exact dosages of all the drugs recommended. The selection of drugs is usually discussed when there is a choice, and the authors' preferences are stated. Acute pulmonary edema and congestive heart failure, the treatment of angina pectoris, coronary insufficiency, coronary occlusion, and anticoagulant therapy are well discussed and presented in an understandable fashion. Many of the rarer emergencies and conditions difficult to diagnose are also described in a practical manner. The section on cardiac arrest is one example of clear, thoughtful writing that should be valuable to one who is not familiar with such an emergency. This book has been kept down to pocket size. Its form and content are excellent, and it should greatly benefit any physician who is likely to encounter cardiac emergencies or patients with heart failure. It also should be of great value to medical students, interns, and residents.

Ciba Foundation Colloquia on Ageing: Volume I: General Aspects. Editors for Ciba Foundation: G. E. W. Wolstenholme, O.B.E., M.A., M.B., and Margaret P. Cameron, M.A., A.B.L.S. Assisted by Joan Etherington. Cloth. $6.75. Pp. 255, with 38 illustrations. Little, Brown and Company, 34 Beacon St., Boston 6, 1955.

In July, 1954, the third Congress of the International Association of Gerontology was held in London. Taking advantage of the availability of many authorities on the problems of aging, the Ciba Foundation at the suggestion of Prof. R. E. Tunbridge invited a number of investigators to attend a workshop session as guests of the foundation the week preceding the congress. That this decision was worthwhile is readily apparent in this report. The first meeting was planned to be a general exploration of the present state of experiments now in process dealing with the changes occurring in human tissues with the passage of time. To keep the content of the discussions informal, the size of the group was limited to 39, of whom 9 were from the United States. Following the opening remarks by Chairman Tunbridge that wisely avoided the semantic pitfalls in which the terms "geriatrics" and "gerontology" unfortunately are involved, the discussions were concerned with aging as a general phase of human existence. This provocative book raises a far greater number of questions than it answers. Although the infinite variety of biological activities going on in the human body at different rates and in different ways make it difficult to establish a common dominant theme, the editors have chosen wisely in the limitation of the topics they selected as a starting point for comments from the members of the group. Senescence is defined after which pathological changes, mental aspects, alterations in respiration, endocrine phases, and problems of nutrition are discussed. The contributions by Lewis on the mental aspects, Lansing on elastic tissue, and McCay on nutrition are particularly stimulating. One of the most valuable features is the discussion at the end of each chapter. Much of the material presented is speculative, and many important aspects of aging could not be included. Even so, this volume should prove helpful to those interested not only in the minutiae of aging but also in practical points of value to the clinician. The publishers deserve the thanks of biologists and the medical profession for presenting an attractive readable book.

The Postural Complex: Observations As to Cause, Diagnosis and Treatment. By Laurence Jones, B.S., M.D. Cloth. $9.75. Pp. 156, with 79 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1955.

Laurence Jones, a surgeon with considerable experience and a special interest in static and postural problems related to the feet, presents the theory that pronation of the feet under weight-bearing produces a forward tilt of the pelvis, exaggerates existing curves of the spine, and thereby produces neuralgias, not only in the lower back but also in the thoracic and cervical regions. Part 1 deals with postural change and evolutionary adaptations but contributes little if anything to the support of the author's theory. It is little more than a review of material that is covered during a first year course on embryology and anatomy in medical school.

Part 2 deals with causes and mechanisms, and in it the postural complex is explained and illustrated schematically by an elaborate diagram. It concludes that "since the central nervous system is a continuous structure, tension in one area must be transmitted in varying degree to all others. Conversely, for the same reason, relaxation of tension may cause corresponding release at distant points." The chapter on radiographic measurements of pelvic position is clear and well illustrated. The importance of making anteroposterior and lateral views with the patient in the standing position is rightly emphasized, and a method for measuring inequality of leg lengths and determining the angle of the pelvic tilt is described. Having explained "that serial distortion of the entire superstructure is triggered by primary internal rotation of the foot," Jones devotes a chapter to synchronized internal rotation of the lower extremity. In addition to the text, it includes a number of diagrammatic explanations of the mechanics and several photographs illustrating the effects of rotary movements of the feet on the alignment of the legs and knees. The author reminds us that the major neurovascular bundles lie close to the inner border of the calcaneus and suggests that descent of the sustentaculum occurs with angular compression of the blood vessels and nerves.

Part 3, on postural history and physical examination, is clearly written and well illustrated, but after one has read through this, he may wonder what has happened to the rest of the patient, since it deals only with his feet, legs, and back.

Part 4 is concerned with treatment. It contains chapters on the suitable shoe—reinforcement and outside correction, the individual inside adjustment of the suitable reinforced shoe, adjuvant therapy, and the correction of foot and body posture in children. The use of rigid shoes with steel shanks and long counters and the use of a plastic reinforcement to form a sort of inside counter or shell are recommended. In addition, most of the inside and outside corrections in common use today are described. Adjuvant therapy is discussed only briefly; this includes bed rest with bilateral balanced (Russell) traction for back pain followed by diathermy and massage and the use of the whirlpool bath for relief of foot and leg pain. The author believes that cortisone, corticotropin, and their derivatives materially shorten the treatment periods. Regarding the treatment of children, the author says that "although there are certain differences, basically the correction of children's shoes resembles adult techniques. . . . High shoes, except for dress purposes, have been chosen as the suitable shoe for children under the age of six." These are reinforced with plastic material and sponge rubber inserts of various types. Correction of intoeing and outtoeing is accomplished by use of training straps attached to reinforced shoes. The author presents a statistical analysis of 500 cases of chronic low back pain from different sources and discusses these briefly. The table is most difficult to evaluate because the symp-

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

toms are classified on a general basis such as fatigue, leg aches, and upper root pain, and the results are designated "substantial benefit" and "failures." The histories and examinations leave many questions unanswered in the minds of the reader. On the basis of the data given, it is impossible to arrive at a critical evaluation.

Faulty body mechanics have been related to pains from the feet to the skull by most orthopedists who followed the suggestions of Goldthwaite and his associates since 1934. In "Essentials of Body Mechanics in Health and Disease," page 22, they state, "In the slender type . . . the body inclines backward from the low lumbar region, increasing the lumbar lordosis and the forward inclination of the pelvis, with an increased rounding of the mid- or upper dorsal region and a forward projection of the neck: . . . In the lower extremities the knees are often hyperextended and the *feet pronated and strained.*" Shands in his "Handbook of Orthopaedic Surgery" described faulty posture thus, "The head protrudes, the shoulders are rounded and drooped, the chest is flat and the thoracic spine has an increased posterior convexity. The lumbar lordosis is exaggerated and the abdomen is protuberant; particularly in the lower half. *The pelvic inclination is increased. The knees are slightly flexed and the feet are pronated.*" Therefore, although most orthopedists recognize the frequent association of pronated, painful feet with certain types of back pain (postural), few will accept Jones' theory that pronated feet are the basic cause of faulty posture and of most neuralgias of the back and legs. Many will also question use of rigid shoes with reinforcements plus other inside and outside corrections as the sole treatment for pronated feet in adults and children.

Jones' book is an interesting exposition of his own theories. It should be used for reference only and only by those with wide experience and critical judgment.

Surgery of the Stomach & Duodenum: A Handbook of Operative Surgery. By Claude E. Welch, M.D., D.Sc., Visiting Surgeon, Massachusetts General Hospital, Boston. Second edition. Cloth. $9. Pp. 370, with 79 illustrations by Muriel McLatchie Miller. Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11, 1955.

The popularity of this handbook of operative surgery is attested by the demand for a second edition. The original format has not been changed, and there has been no significant revision of the material presented in the first edition, but new subjects have been added which enhance the value of the book. Of particular interest is a brief historical summary of the development of gastric surgery. The newer operations for duodenal ulcer, including tubular resection and extensive sleeve resection, are presented, as well as replacement techniques used after gastrectomy. Brief comments on subjects of current interest, such as the revival of interest in the Billroth 1 procedure and immediate gastric resection as the treatment for the acutely perforated ulcer, are also included. The important feature remains an accurate description of the technical aspects of gastric and duodenal operations, with discussion kept to a minimum. A good bibliography is included. This handbook should be a welcome addition to the library of all surgeons interested in this field, and it is highly recommended to all surgical residents.

Medical Problems of Old Age. By A. N. Exton-Smith, M.A., M.D., M.R.C.P., Physician, Whittington Hospital, London, England. With foreword by Rt. Hon. Lord Amulree, M.A., M.D., F.R.C.P. Cloth. $7. Pp. 331, with 17 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2; John Wright & Sons, Ltd., 42-44, Triangle West, Bristol 8, England, 1955.

Leadership in important medical fields has been demonstrated many times by members of the profession in Great Britain. As early as 1922, Sir Humphry Rolleston in his Linacre Lectures recognized the increasing importance to the medical profession of the afflictions and deteriorations that are the common experiences of many older persons. Since Rolleston discussed medical aspects of old age, there has been a growing awareness of this field. Although articles and monographs on selected phases have been published, no textbook dealing specifically with the vexing medical problems of older citizens has previously appeared in Great Britain. This concise practical treatise on the diagnosis, management, and general considerations of health maintenance and medical service for the growing number of the elderly is an attractive handbook with an excellent index. In the foreword, Lord Amulree emphasizes the comparative newness of geriatrics and points out that in the past too many elderly patients have not received adequate treatment. It appears that in Great Britain, as in the United States, physicians as a group have not informed themselves of the specialized nature of the health and medical needs of the elderly. Here, then, is an informative and helpful workbook that tells how the sympathetic, resourceful physician may solve medical problems of the aged. The first chapter outlines the clinical implications of aging. Succeeding chapters discuss general principles of diagnosis, the maintenance of health, home care, and rehabilitation. Next, the disorders of the major body systems are interpreted. The final chapter reviews the common mental disorders that occur in Great Britain. They are pretty much the same as those found in the United States. The absence of a discussion of the new tranquilizing drugs is not a serious omission since, as yet, exact indications for their use and their scopes of effectiveness have not been determined. The roentgenograms and other illustrations are well selected. The author is to be congratulated on this contribution, and the publisher is to be commended for the excellence of the format, readability, and general arrangement of the material.

Psychiatry and the Law: Edited by Paul H. Hoch, M.D., New York State Psychiatric Institute, and Joseph Zubin, Ph.D., New York State Psychiatric Institute, New York. Proceedings of forty-third annual meeting of American Psychopathological Association, held in New York City, June, 1953. Cloth. $5.50. Pp. 232, with 3 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 99 Great Russell St., London, W.C.1, England, 1955.

This book has the same title as a textbook twice its size by Guttmacher and Weihoffen published in 1952. It is hoped that readers will not confuse the two. Because the book is a report of proceedings, it lacks the complete coverage and continuity of a textbook. The papers reprinted in this collection, however, are scholarly presentations, and most of them are well worth reading. Perhaps most interesting to those psychiatrists and lawyers faced with the problem of the defense of insanity in criminal cases are the discussions by Davidson, Abrahamsen, Roche, and Barshay. The test used in most states today when insanity is interposed as a defense to a criminal act is the rule established in the M'Naghten case in England in 1843. Great strides have been made in the field of psychiatry since that time, and the continued use of this century-old concept has often been cited as a perfect example of the lag between scientific advancement and the law's acceptance of such advances. The above discussions, presenting both sides of the issue, show that there are still grave doubts as to the wisdom of abandoning a concept that has aided the administration of justice pretty well for over 100 years. As valid studies in this field appear, a better understanding between exponents of law and psychiatry is bound to result.

How to Live 365 Days a Year. By John A. Schindler, M.D., Chairman, Department of Medicine, Monroe Clinic, Monroe, Wis. Cloth. $3.95. Pp. 222. Prentice-Hall, Inc., 70 Fifth Ave., New York 11, 1954.

This book written for the laity describes the causes and treatment of emotionally induced illnesses. Despite the vast literature on the psychosomatic element in many diseases, there is much in this book that should be of value to the average clinician. The style is fairly lucid, although at times there is a tendency to use technical terms that do not belong in a popular treatise. For example, why "cicatrix" rather than "scar?" Such lapses fortunately are few, and every point is concretely illustrated with an apt case history. As in many other books aimed at self-help, the principles expounded, sound though they are, are very difficult of application, and one is left with the feeling that, in addition to the sound advice given, many of these patients would have been further benefited or would have achieved relief sooner if they had been given definite instructions in how to relax their voluntary muscles. The author emphasizes his most important points by repeating them in summaries at the end of each chapter and in a "final blueprint" near the end of the book. This is followed by a short chapter for physicians explaining in more detail the author's views, how he arrived at them, and how he applies them in his practice. There is an index. As a book to give to patients with emotionally induced illness, this is one of the best.

QUERIES AND MINOR NOTES

ACNE AND CHRONIC HEPATITIS

To the Editor:—*A 28-year-old man has had chronic hepatitis for three years. It had an insidious onset, and its progress is marked chiefly by a progressive increase of bromsulphalein retention, which is now 20% in 45 minutes. One factor responsible for this progress is a severe cystic acne vulgaris of the back. The patient had acne prior to the hepatitis, but this had cleared completely two years before the onset of the hepatitis. Six months after the onset of the hepatitis, the acne recurred in a more severe form. Is there a factor in the hepatitis responsible for this increased severity that can be treated? Is hormone medication to be considered?*

Howard L. Gordon, M.D., Hillside, N. J.

Answer.—The acne vulgaris in this patient may be secondary to the exacerbation of the chronic hepatitis rather than vice versa. When acne is present in chronic hepatitis, antibiotic therapy, which will also reduce the organisms in the intestinal tract, should also be utilized. Thus, any one of the broad spectrum antibiotics in moderate doses might be useful. Neomycin could also be added to reduce the intestinal flora. On occasion, cortisone, hydrocortisone, or corticotropin have been of help in chronic hepatitis, and their efficacy should be tested in such cases.

DENTAL CARIES

To the Editor:—*In my pediatric practice, several patients have asked about the following advice given by dentists for children with severe caries, namely, that they must eliminate all sweets from the diet including fruits and other naturally occurring sugars. One mother actually was in tears after trying to prepare a diet eliminating all carbohydrates. 1. Are sugar and other carbohydrates of primary importance in dental caries. 2. What sort of a diet would be advisable yet practical? 3. Does not heredity play a major role in dental caries?*

M.D., California.

Answer.—The problem of dental caries has been vigorously attacked by research and clinical investigators with no final answer of single etiology nor prophylaxis yet available. Answers given here conform to findings of more than one investigator in each case. 1. Sugar as a substrate for acidogenic fermentation in the mouth is of importance in the caries-susceptible individual. As "sugar" particular reference is made to glucose and sucrose separately or in prepared foods. Polysaccharides allow fermentation-degradation productive of acid at a much slower rate. Ninety per cent of the caries reduction accomplished by sharp limitation of all carbohydrates has been accomplished by removal of monosaccharides and disaccharides. 2. Complete elimination of carbohydrates from the diet is untenable, and as in the correspondent's case, virtually impossible. An advisable diet for such a caries-susceptible child should be free of jams, jellies, candy, heavily sugared beverages, canned (sweetened) fruits, sweetened pastries, and canned peas or corn. Recent confirmed evidence of caries activity during and for about 15 minutes after each feeding correlate well with higher caries activity in those who spend greater time in feeding either by slow eating, or frequent, between-meals supplements. Glutinous foods result in greater caries activity than those of thinner consistency by their prolonged apposition to the tooth. These two factors have made it worth while to advise caries-susceptible individuals to brush teeth, or at least rinse the mouth thoroughly after each meal. An excellent, simple, and explicit dietary is available (Dietary Program for the Control of Dental Caries, Ann Arbor, Mich., Overbeck Company, 1951). 3. Heredity does play a major role in dental caries, but until man exhibits the same care in choosing a mate as in the purchase of horses or cattle the "outbreeding" of dental caries is unlikely. Five factors evident in this problem have been detailed as: (*a*) genetic history, (*b*) developmental-nutritional background, (*c*) salivary-dental interrelationship, (*d*) oral micro-organisms, and (*e*) oral food debris. Dietary control active through factors, *b*, *d*, and *e* has given the best clinical results (over 80% experienced a definite reduction in caries incidence) in caries control for the caries-susceptible individual.

INFANT FEEDING AND CIRCUMCISION

To the Editor:—*Please furnish information on the following subjects: (1) the age to start solid foods in healthy term infants, (2) what solid foods to start at what age and the reasons for the same, and (3) the best age, in days or weeks, for circumcision and the reasons for same.*

Allison B. Willeford, M.D., Molalla, Ore.

Answer.—1. The pendulum is swinging back from the very early starting of solid foods in healthy infants to a more moderate view. The reason is that infants thrive nutritionally on both regimens and there is less likelihood of digestion upsets. Under age 3 months, if the infant is on a proper composition milk formula, solid foods are not necessary until the infant acts hungry and demands them. This varies from infant to infant, some not being satisfied with the milk formula as young as 2 weeks of age, although the average is about 2 months. 2. Cereals are usually the first solid food started because they are easily digested and high in calories. In infants showing a dislike for cereal, strained fruits, such as applesauce, pears, or bananas may be mixed with the cereal or temporarily substituted for it. Strained vegetables, meats, or mixtures of them usually are introduced at age 3 months, in some infants earlier. These foods provide such body needs as iron, other minerals, vitamins, and proteins. Egg yolks and infant desserts, such as gelatin, custards and pudding may be started between the age of 4 and 5 months. The time-honored age for circumcision is about the end of the first week of life. The theoretical reason for this is that the coagulation of the infant's blood is somewhat diminished after birth but returns to normal by the 6th to 8th day of life. However, in some hospitals circumcision is done soon after birth on the first day of life without any unusual amount of bleeding.

CONVULSIONS OF CHILDHOOD

To the Editor:—*I would like information about fatal asphyxia resulting from the convulsions of childhood that are caused by rapidly rising temperature. Physicians generally seem to regard these convulsions as more alarming to parents than dangerous to the child. Having seen a few cases where the child became blue and limp and showed no sign of resuming respiration without aid. I wonder if these convulsions are entirely without mortality. I am not referring to convulsions from disease or injury primarily involving the central nervous system.*

Hugh A. Thompson, M.D., Raleigh, N. C.

Answer.—Death resulting from asphyxia during a febrile convulsion must be rare, if it occurs. However, it has been shown that febrile convulsions may involve more or less severe brain damage. About 5 to 10% of the children show residual paralysis, electroencephalogram changes, or other signs of brain injury, usually clearing up promptly but sometimes lasting several days or months. Various reports have indicated that from 5% to as high as 60% of children who suffered febrile convulsions developed epilepsy in later life. Certainly there is a direct relation between the duration and severity of the initial febrile convulsion and development of epilepsy later. Therefore, it is important that the convulsion be stopped as soon as possible with sedatives and measures to reduce the fever.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

BUCKWHEAT POISONING

To the Editor:—*I would like information on fagopyrism (buckwheat poisoning).*

H. Wayne Glotfelty, M.D., Piqua, Ohio.

Answer.—Foremostly, fagopyrism is a disease of farm animals, notably cattle and sheep, attributed to photodynamic action but always subsequent to feeding on some member of fagopyrum, the genus to which the buckwheats belong. Much effort has been exerted to determine the precise photosensitizing agent, but this has not been accomplished. This agent appears to exist in the roots, stems, flowers, and grain of the buckwheats. Animals fed on buckwheat and then kept in semidarkness or total darkness do not develop the disease. Mild damage is reflected in skin surface injury. Severity may be apparent through intestinal and pulmonary hemorrhage, enteritis, bony necrosis, emaciation, and other manifestations. That fagopyrism may occur in man is doubted despite the tradition that buckwheat should not be eaten during the summer months less "buckwheat rash" appear. It is probably true that man is susceptible to the action of buckwheat in the provocation of light sensitivity, but the quantity ingested through the judicious consumption of buckwheat cakes appears to be insufficient. Extensive information may be found in Bl[illegible] "Photodynamic Action and Diseases Caused by Light", (American Chemical Society Monograph Series, no. 85, New York, Reinhold Publishing Corporation, 1941).

MONOCULAR DIPLOPIA

To the Editor:—*What are the causes of monocular diplopia?*

M.D., Pennsylvania.

Answer.—The causes of monocular diplopia are discussed by Duke-Elder (Textbook of Ophthalmology, vol. 4, London, England, Henry Kimptom, 1949, p. 3866). It may be due to (1) optical causes in the eye, (2) simultaneous conscious appreciation of two systems of visual projection, or (3) dissociative cerebral lesions. Optical causes include irregular corneal astigmatism, parenchymatous keratitis, and other influences disturbing corneal refraction; a double pupil or an iridodialysis; dissociation or subluxation of the lens; refractive irregularities due to incipient cataracts; fluid clefts or developmental anomalies of the lens; air bubbles, transparent foreign bodies, crystals, or cysts in the aqueous or vitreous fluid; and retinal detachment, particularly if the retina becomes inverted. Projectional diplopia arises from abnormal retinal correspondence, either through a single retinal image acquiring two associations of direction or by the image seen by the eccentric retinal point around which an abnormal system of correspondence is centered, being brought into consciousness simultaneously with the macular image. Central uniocular diplopia may occur in hemianopia and hemiamblyopia due to a calcarine lesion or to paresis of the extraocular muscles in association with a gross cerebral lesion.

FOODS RICH IN ARGININE

To the Editor:—*I would like a list of the foods rich in arginine. Is there any normal or abnormal process in the body that can increase the production of arginine endogenously? Have the organisms, chemicals, or enzymes been identified that produce the putrefaction of albuminous material in the intestinal tract, and can such a process take place in other tissues of the living organism? Are there any chemicals, drugs, or antienzymes known that may hinder or prevent such changes in albumen or proteins?*

Mitchell Burdick, M.D., Erie, Pa.

Answer.—Most proteins contain a good amount of arginine. Gelatin is one of the richest sources, with meat, legumes, eggs, and cereal proteins following in order. Arginine can be synthesized in the body, but the rate of synthesis is not sufficient to meet the requirements in rapidly growing animals. The organisms involved in the putrefaction of protein material in the intestinal tract are the coliform organisms. The enzymes involved are the decarboxylases and the deaminases. These enzymes have been studied largely in bacteria, but they have also been found in animal tissues. These enzymes are undoubtedly utilized in the normal metabolism of amino acids, but it is possible that under abnormal conditions compounds may be produced that have a deleterious effect. Little work has been done on the antienzymes related to these mechanisms. It is, of course, possible to reduce the number of coliforms in the intestinal tract with sulfonamides and antibiotics.

PENICILLIN

To the Editor:—*A 25-year-old man has been given occasional 10-day courses of procaine penicillin in sesame oil with aluminum monostearate injected every other day. There have been several courses a year for six years; it is given prophylactically to prevent otitis media, which never fails to occur as a complication of any head cold unless it be prevented by penicillin. Careful study has been made of the nasopharynx, and no further treatment is possible directed toward avoiding the susceptibility to ear complications. This man has never shown any untoward effects from penicillin. What is the likelihood of sensitization occurring from this therapy in the future? Several of the injection sites still have a palpable bump. Is this caused by the oil medium, and is there any danger of a malignant change in it?*

Edme Regnier, M.D., Salem, Mass.

Answer.—There is no clear-cut, statistical answer relative to the likelihood of the given patient developing sensitivity to procaine penicillin. Various reports are extant relative to sensitization of groups of patients to penicillin. These range from 3 to 10% when all reactions of sensitization are taken into account. It appears from certain of the reports that the more frequent the repetition of courses of penicillin in a patient, the greater the likelihood of sensitization. Definite information is available that people who are allergic to a number of other sensitizing substances become more easily sensitized to penicillin than do those patients who have no allergic history. Also, it is known that when penicillin is used topically the chances of sensitization appear to be greater. The "bumps" that have been described probably represent the characteristic action of the tissues toward certain vegetable oils. These occur not infrequently when any therapeutic agent containing oil is used intramuscularly. As far as known, there have been no reports of malignant lesions developing in these granulomas that follow the injection of penicillin in oil. It can be suggested that if benzathine penicillin is used instead of procaine penicillin in oil the development of these will not take place.

PREVENTION OF BLOCKING OF INDWELLING CATHETER

To the Editor:—*In* The Journal, *Aug. 6, 1955, page 1329, a question was asked regarding the formula for irrigating solution to use in an indwelling catheter in the urinary bladder to prevent blocking by deposition of crystals. I would agree with the answer but I do not feel that it is complete. Dr. Suby of Boston has been working for a number of years with various solutions with the aim of trying to dissolve urinary calculi. He contributed much to our information. His solution G is very useful in irrigating indwelling catheters to decrease the amount of blockage that takes place by the deposition of crystals. Many people will tolerate a catheter or a suprapubic tube for a period of time, but, sooner or later, urinary salts are deposited on the lining of the tube and, if allowed to go long enough, may completely block the lumen. By the use of Suby's solution G, while this cannot be entirely prevented for an indefinite period of time, still it may be slowed down so that the tube remains clean and free of crystals for a much longer period than it would be without them. Solution G contains citric acid monohydrate, 32.5 gm.; magnesium oxide, anhydrous, 3.84 gm.; sodium carbonate, anhydrous, 4.37 gm.; and distilled water, 1,000 cc. The reaction of the solution is pH 4. One must remember that to irrigate the bladder two or three times a day with an Asepto syringe and solution may cause the bladder to become irritable as a result of this acid pH. This may produce some slight tendency to bladder spasm and even on occasion some blood in the irrigating fluid; however, this will usually subside if the irrigations are stopped for two or three days and then resumed.*

RESUSCITATION OF THE NEWBORN INFANT

Ralph M. Tovell, M.D., William K. Bannister, M.D.
and
David M. Little, M.D., Hartford, Conn.

This discussion concerns the role of oxygen and carbon dioxide in resuscitation of the newborn infant and the action of analeptic drugs and antidotes for analgesics and hypnotics administered to the mother during labor. Asphyxia neonatorium is a chemical phenomenon associated with a decrease in the concentration of oxygen, an increased tension of carbon dioxide, a marked increase in lactic acid, and a decrease in the pH of the fetal blood. In the normal newborn infant, the arterial oxygen capacity is high (20.8 vol. %), the arterial oxygen content low (10.5 vol. %), and the arterial oxygen saturation, therefore, low (50.5%); in asphyxia neonatorum, the oxygen content of the blood may fall to less than 1 vol. % in fatal instances and the oxygen saturation may be between 0.5 and 4.0%. The lactic acid content of the blood of the normal newborn infant is 35 mg. per 100 cc., but under conditions of asphyxia this may rise to from 85 to 90 mg. per 100 cc., which indicates a definite endogenous production. The carbon dioxide tension of the blood, which is normally 32 mm. Hg in the newborn infant, rises to twice that value in asphyxia neonatorum, and at the same time the carbon dioxide content falls to low levels as a result of its displacement from base by the large amount of lactic acid in the blood. The pH of the blood, normally 7.35 in the newborn infant, falls to 7.05, the lower level compatible with life, and may even fall below 7.0. Thus, although the changes in lactic acid content, pH, and carbon dioxide tension are marked, these changes are secondary. The primary chemical change in asphyxia neonatorum is the extreme reduction in the oxygen content of the infant's blood.

USE OF OXYGEN AND CARBON DIOXIDE

Since the transport of oxygen to the depressed cells of the respiratory center of the newborn infant is the object of resuscitation, this process may be aided by providing an atmosphere high in oxygen for the baby who is trying to breathe and forcing it, in controlled fashion, into the unexpanded lungs where apnea is in evidence. Oxygen, therefore, may be considered an agent for supporting cerebral activity and the medium for providing an expansile force to collapsed and cohesive alveoli. If, as Dr. Potter maintains in her discussion of the state of the lungs at birth (this issue, page 1341), the newborn lung is rarely the cause of asphyxia in babies of over 28 weeks' gestation, one is in essence treating the cells of the respiratory center and the syncytium of cardiac muscular fibers pumping blood and oxygen to the brain. For sake of discussion, it may be presumed that the myocardium and not the brain is the critical tissue in resuscitation, for a failing circulation will transport less and less oxygen to the brain no matter how well the infant's lungs are supplied with it. The thesis that hypoxia depresses cardiac activity more readily than it does cerebral activity may have credence. The best index for evaluating the progress of an asphyxiated baby is the character and rate of the heartbeat. So long as it maintains a rapid regular rate, resuscitation is being conducted along effective lines. When the heart falters, however, as exemplified by either an extremely rapid rate or by bradycardia, the resuscitator must quickly realize that his procedures are less effective than they should be. The important thing is that oxygen be administered effectively and early. Appropriate equipment for administration of oxygen should be available in every delivery room, and there is no excuse for procrastination before using it, whether the newborn infant is asphyxiated or not.

Carbon dioxide is a gaseous agent, the administration of which has been widely advocated in the past as a powerful stimulant to the respiratory center. It is universally accepted that carbon dioxide in soluble form in the blood is the main regulator of breathing to the healthy brain. It is also known that carbon dioxide when in high concentration in the plasma becomes an anesthetic agent. It has been previously shown that the concentration of carbon dioxide in an asphyxiated baby's blood is higher than normal. It has been recognized that administration of carbon dioxide along with the oxygen

Read in the Panel Discussion on Resuscitation of the Newborn Infant before the Joint Meeting of the Section on Anesthesiology, the Section on Diseases of the Chest, the Section on General Practice, the Section on Obstetrics and Gynecology, and the Section on Pediatrics at the 104th Annual Meeting of the American Medical Association, Atlantic City, June 9, 1955.

used for support of life in the newborn infant fails to stimulate a respiratory center already subjected to an abnormally high concentration of carbon dioxide in plasma. Although in past years carbon dioxide was frequently employed in concentrations from 3 to 7%, in most maternity hospitals its use has been abandoned because of its ineffectiveness and because of its real hazards.

USE OF ANALEPTIC DRUGS

The administration of the analeptic drugs pentylenetetrazol (Metrazol), nikethamide (Coramine), and alpha-lobeline during infant resuscitation can produce a mild and fleeting stimulation. Usually only a few uncoordinated gasps ensue. The danger of their employment lies in the fact that they can be potent convulsive agents. If an asphyxiated baby has a convulsion, precious oxygen is consumed and death follows immediately. The dose of an analeptic that produces effective stimulation of the respiratory center is so close to the convulsant dose that there is little margin of safety. Circulatory failure that accompanies asphyxia will be responsible for slow absorption of any analeptic administered. The resuscitator, in the belief that more drug is required to obtain or maintain an effect, may repeat the dose. In the presence of an improving circulation, the full effect of the total amount of analeptic given may reach the brain in an overwhelming dose, with the result that a convulsion occurs and death follows. The real tragedy is that this dire event occurs after improvement has been effected. For these reasons analeptics should be discarded in the treatment of asphyxia.

It has been stated that analgesia for mothers produces some degree of depression for the newborn infant. The administration of nalorphine (Nalline) gives some promise of combatting the effects of analgesic drugs administered to mothers during labor. After the administration of morphine, meperidine (Demerol), or methadone, nalorphine has a specific action toward improvement of respiratory and circulatory function. It has no salutary effect on the depression produced by the barbiturates. When it is given to subjects who are not depressed by a narcotic drug, it may act like morphine and produce a depressant effect on respiration. In those instances where respiratory depression is due to the barbiturate rather than to the narcotic that has been given as well, the administration of nalorphine may be productive of a convulsion. These hazards must be kept in mind. It is possible that the administration of nalorphine in doses of 5 or 10 mg. to the mother 5 or 10 minutes prior to delivery may have a salutary effect in combatting respiratory depression in the newborn infant. It will have no effect if the depression of the newborn infant is due to the barbiturates given to the mother or if the depression is due to forces to which the newborn infant was subjected during labor and delivery. Therefore the resuscitator should place no reliance on the action of nalorphine.

COMMENT

If the armamentarium for the treatment of asphyxia neonatorum seems short, consisting as it does of establishing an airway and administering oxygen, a high rate of salvage can be achieved. The most important factor is the experience and judgment of the resuscitator. If he is forewarned of danger, if he has his equipment assembled and ready for use, and if he uses his chosen method of resuscitation well, successful resuscitation will in the majority of instances be his reward. Babies who have failed to respond to resuscitation for as long as 45 minutes subsequently may leave the hospital with every evidence of being normal infants. What the future holds for these infants is conjectural, but while life persists one must try to preserve it. An attitude of defeatism should never be allowed to prevail.

80 Seymour St. (Dr. Tovell).

ROLE OF THE LARYNGOLOGIST IN RESUSCITATION OF THE NEWBORN INFANT

Paul H. Holinger, M.D., Chicago

As a member of the medical-surgical team caring for the newborn infant, the laryngologist is a consultant who is called when the question of airway obstruction arises. He is responsible for the establishment and maintenance of a clear airway; he must determine the point of obstruction when obstruction exists and either remove it or circumvent it. If obstruction is not causing the asphyxia that is present, he must be able to give assurance that the airway is clear, if this is questioned. As a rule, the laryngologist is called after it is apparent that the infant has not responded to the usual methods of resuscitation or aspiration of secretions. This varies in time after delivery from a few minutes to a few days, depending on a number of factors but most directly upon the severity of the infant's condition.

TYPES OF OBSTRUCTION

The most frequent consultation received is a request to aspirate secretions or to aspirate a "mucous plug" causing a lobar or unilateral atelectasis. In this regard, it should be stated that in my experience, the pressure of excessive mucus in the tracheobronchial tree or the presence of unilateral or anatomically lobar atelectasis indicates additional, more basic pathology. The diagnosis of the basic pathology, i. e., the cause of the excessive mucus or atelectasis, is as important, if not more so, than the aspiration itself. In some instances, such as pharyngeal and laryngeal paralysis associated with massive cerebral hemorrhage, bronchoscopic aspiration may

---

Read in the Panel Discussion on Resuscitation of the Newborn Infant before the Joint Meeting of the Section on Anesthesiology, the Section on Diseases of the Chest, the Section on General Practice, the Section on Obstretrics and Gynecology, and the Section on Pediatrics at the 104th Annual Meeting of the American Medical Association, Atlantic City, June 9, 1955.

actually be contraindicated. In other cases the diagnostic findings may indicate urgent, immediate surgical intervention such as a tracheotomy, a thoracotomy, or a repair of a tracheoesophageal fistula.

Because of these possibilities, a rapid differential diagnosis is necessary in the cyanotic infant suspected of having respiratory obstruction. It should first be determined whether the infant's cyanosis is on the basis of a central nervous system lesion, a cardiac lesion, or respiratory tract lesion. If there is a central nervous system lesion, the reflexes are severely impaired or absent and the infant is flaccid and unresponsive. With these findings, one should reduce instrumentation to a minimum except for the simplest pharyngeal suction. The insertion of a small intratracheal tube will establish an airway and permit occasional tracheal aspiration. But repeated blind or even direct aspiration efforts are only too likely to increase the cerebral damage. If cyanosis is due to a cardiac lesion, the cyanosis is not associated with respiratory effort; other signs would be a cardiac murmur, irregularity in rate or rhythm, and enlargement or displacement of the heart. If the respiratory system is responsible, respirations are usually labored; dyspnea is associated with hard breathing and accompanied by the signs of air hunger such as suprasternal and epigastric indrawing, restlessness, wheezing, or stridor.

If the previous differentiation has indicated the infant's cyanosis is not on a central nervous system or a cardiac basis but is probably due to a lesion in the respiratory system, attention is then directed to further localization in three possible sites: the pleural cavity, the lung, or the airway. A chest x-ray examination will assist in this differentiation and should include a lateral film of the neck and chest as well as the routine posterioanterior flat film. Pulmonary lesions such as serious congenital anomalies, patchy or lobar atelectasis, areas of pneumonic consolidation, or localized emphysema are more clearly identified on the chest film than by physical examination. Pleural fluid, on the other hand, is generally found or eliminated from further consideration by the physical signs. However, spontaneous pneumothorax in the newborn may be overlooked on physical examination and because it produces all the signs and symptoms of acute respiratory tract obstruction may mistakenly be treated as such. Thus, the films may accurately direct a bronchoscopic examination or therapeutic aspiration of a specific area or bronchus; conversely, they may show findings such as a pneumonia or a pneumothorax that would contraindicate laryngoscopy or bronchoscopy.

If, however, the examination to this point has indicated that the lesion is in the respiratory tract and the pleural cavities and lungs have been eliminated as possible sites, effort is directed toward localization within the airway itself. Again, for purposes of differentiation, the airway may be divided into three general areas of possible obstruction: nasopharyngeal, laryngeal, or tracheobronchial. Here rapid differentiation may be based largely on the character of the voice or cry. A stertorous, rasping inspiratory sound characterizes the high obstruction associated with choanal atresia, pharyngeal paralysis, micrognathia, or a thyroglossal duct cyst. Nursing is associated with episodes of cyanosis because the nursing infant must use the postnasal and pharyngeal airway. Postnasal obstruction is determined by the inability to pass a small catheter through the nose into the pharynx; pharyngeal paralysis by the lack of a gag reflex; and a thyroglossal duct cyst by palpation of the base of the tongue. In conditions in which the tongue itself causes the obstruction, such as micrognathia or macroglossia, relief of obstruction is immediately apparent if the tongue is held forward with a gauze sponge.

Respiratory obstruction in the newborn infant due to a laryngeal lesion is characterized by rapid, labored breathing with indrawing in the suprasternal notch and epigastrium, and, most significant, an abnormal character of the cry, which may be weak, aspirate, husky, or absent. Congenital laryngeal webs or cysts, subglottic stenosis, and unilateral or bilateral paralysis of the larynx associated with cerebral agenesis will produce these changes in the cry. Direct laryngoscopy is essential in establishing the diagnosis, but before proceeding with this examination one should be prepared to carry out intralaryngeal procedures such as aspirating the contents of an obstructing cyst to establish an airway if obstruction is found. The passage through the larynx of an infant bronchoscope with oxygen attached is the most rapid means of establishing the airway under these circumstances. If necessary, it may then be maintained by a tracheotomy.

If the obstruction is in the trachea or bronchi, the signs are the same as for higher obstruction, but the cry is clear. X-rays demonstrating a unilateral obstructive emphysema or atelectasis make it imperative that a bronchoscopic examination be made. An obstructing bronchial plug and a pulmonary agenesis give identical physical and x-ray findings; only direct inspection differentiates them, when either the plug is aspirated or the absence of the bronchus is demonstrated. Obstruction due to excessive secretions not relieved by simple tracheal aspiration generally indicates a pharyngeal paralysis or a congenital esophageal anomaly such as congenital esophageal stenosis or atresia with or without a tracheoesophageal fistula. Tracheal or bronchial webs are rare but respond to dilatation. If external tracheal or bronchial compression is seen, or the extremely interesting idiopathic lobar emphysema is found responsible for the obstructive phenomena, immediate thoracic surgical consultation is indicated.

SUMMARY

In summary, the following statements are made in answer to the question "For what clinical situations should the laryngologist be called?" 1. In respiratory obstruction. Respiratory effort without adequate air intake, particularly if associated with a hoarse or absent cry, indicates probable respiratory obstruction, which the laryngologist may be able to demonstrate and treat. 2. Aspiration. When the laryngologist is called for aspiration of excessive mucus from the pharynx and tracheobronchial tree, such lesions as cerebral agenesis or birth injury with associated pharyngeal and laryngeal paralysis should be considered as well as congenital esophageal anomalies with or without tracheoesophageal fistula. 3.

Atelectasis or emphysema. Lobar or total unilateral atelectasis or obstructive emphysema are oftener present on the basis of a congenital anomaly than due to a "mucous plug." However, it is futile to think a widespread, congenital atelectasis can be relieved by aspiration of a "mucous plug" if no rales are present in the chest. But since respiratory tract obstruction is fairly common, inspection in localized atelectasis or emphysema is essential.

Thus, the role of the laryngologist in resuscitation of the newborn infant is in establishing and maintaining an airway. His own studies should localize the lesion as far as possible. Examination of the cyanotic, dyspneic infant should determine first if the lesion is a central nervous system lesion, a cardiac lesion, or a respiratory tract lesion. If respiratory, is it pleural, pulmonary, or airway? If it is airway obstruction, is it nasopharyngeal, laryngeal, or tracheobronchial? Direct laryngoscopy and bronchoscopy are his special means of answering this last question. Proper newborn-size endoscopic instruments must be available. A tracheotomy may be necessary, and the endoscopic examination should not be made without adequate preparation for it, not because of the procedure itself, but because of the pathology that may be found responsible for the obstruction. Finally, while the most frequent consultation with the laryngologist in regard to newborn infants is a request to aspirate obstructing secretions, it is almost axiomatic that, if obstruction is severe enough or secretions copious enough to necessitate this consultation, some underlying congenital anomaly or birth injury is the basic pathology responsible for the infant's condition and not the secretions themselves.

EXPANSION OF THE LUNGS OF NEWBORN INFANTS

Richard L. Day, M.D., Brooklyn, N. Y.

The *normal newborn infant is able to expand his* lungs so easily that he seems not to struggle at all, and in a few minutes the oxygen saturation of his blood is over 90%. In the operating room, the anesthesiologist can maintain pulmonary ventilation during chest operations on newborn infants with ease. In the delivery room, however, one encounters, fortunately rather rarely, infants who cannot breathe adequately, and in such infants, artificial positive-pressure respiration is much less successful than in the operating room where normal lungs are dealt with. The difficulty seems to arise from three possible causes: 1. The lungs may be obstructed by debris. 2. The lungs may be too immature to expand well. 3. The normal neonatal lung may require more than the 15 cm. H_2O (11.5 mm. Hg) permitted on most positive-pressure resuscitation devices. Since the first two difficulties are discussed by others (see pages 1337-1340 and 1341-1342), I shall discuss pressures and volumes in expansion of the neonatal lung but at the same time emphasize that these factors obviously underlie other hindrances that may exist.

Observations by many workers indicate that the kind of neonatal lung seen at autopsy seldom can be expanded at 20 cm. H_2O air pressure. No one knows what pressure is needed in the case of the normal lung of an infant who survives, though it is known from the work of Smith and Chisholm[1] that the infant is capable of exerting over 40 cm. H_2O inflating pressure.

SHORT DURATION PRESSURES

Rat lungs that have been rendered totally atelectatic by oxygen breathing prior to tracheal occlusion seldom *open at 20 cm. H_2O and usually but not always will* open at 30 cm. It is not unlikely that the kind of lung one confronts in an infant who needs active resuscitation resembles both these rat lungs and those infant lungs studied by Wilson and Farber, so that, in a truly apneic infant, one would not expect success at conventional pressures. *To insure inflation, one should use pressures* at least over 30 cm. H_2O and probably up to 40 cm. Such pressures can be rendered safe by controlling their duration. The normal infant probably has a duration of inspiration of less than 0.75 second. Using a tracheal catheter, Apgar[2] has found that lungs are uninjured at pressures up to 50 cm. or even above exerted for half a second with one particular intratracheal tube. In rats, pressures of 40 cm. for 0.2 second are safe with a tracheal cannula of the correct size but not with a larger one. In all these calibrations, one must take into account the size of the orifice and the amount of expandable lung. If one advocates use of an intratracheal catheter, the size of the orifice is crucial. It is the volume of air, in relation to expandable lung, in the final analysis, which defines safety. Each operator must study his particular apparatus in the autopsy room with the utmost care.

Short duration pressures have two other advantages in addition to their safety. The first is that there is less impairment of venous return to the heart. Pressures exerted for several seconds must, especially in the case of an infant on the verge of shock, be exceedingly detrimental to cardiac output. Secondly, short, high pressures, similar to those exerted by the normal infant, decreased the amount of expansion of easily expandable parts of the lungs as compared with that of the more resistant areas. This point is clearly shown in experiments on paired rat lungs, one of which is normal and the other atelectatic. With a short period of increased intratracheal pressure at an adequate level, more uniform expansion is achieved.

CONCLUSIONS

No clinical studies have ever been performed on any large group of newborn infants, to my knowledge, that show a clear advantage of any particular method of resuscitation. I have a perfectly open mind on the question of whether infants left entirely alone might not do as well as those treated by any method. Such studies would be difficult, but I believe that those of us who work in centers where research can be carried out are obligated to settle this most confusing problem of infant resuscitation. My only plea is that, if one does believe in positive-pressure methods, he should apply them as physiologically as possible. By this I mean he should imitate the baby. A few initial "breaths" at say 30 to 40 cm. for short intervals, perhaps half a second, should be succeeded by conventional positive-pressure respiration. The fear of rupture is overrated. In my experience, rupture has occurred either as a result of the infant's own struggles or of gross disregard of physiological principles. Whatever apparatus or technique is chosen, the physician should practice on a dead subject.

STATE OF THE LUNGS AT BIRTH

Edith L. Potter, M.D., Ph.D., Chicago

The lungs, during intrauterine life, pass through two principal stages of development. The first, which occupies about the first half of fetal life, is a period of increasing elongation and ramification of an original bud arising from the entodermal tube. During this time cells differentiate into proximal tall columnar bronchial epithelium, intermediate cuboidal epithelium, and terminal actively growing buds made up of very large cells with prominent basal vacuoles. These terminal buds incite the local proliferation of mesoderm so that each elongating tubular branch becomes surrounded by a sheath of connective tissue. The lobular pattern is very prominent at this time, owing to the close investiture of the entoderm by mesoderm.

Throughout fetal life an increasing number of branches are produced; as they become more numerous their external surfaces become more closely approximated. The connective tissue sheaths lose their individuality and merge indistinguishably with those adjacent to them. The proportionate amount of space occupied by the connective tissue diminishes constantly during the last half of fetal life, and at term connective tissue is visible only as a very fine network supporting alveolar capillaries.

DEVELOPMENT OF LUNGS

The second phase of development is primarily one of vascularization. In the first stage the growing blood vessels follow the same pattern as the pulmonary tree but lie free in the mesoderm. As they proliferate they come to lie closer to the outer surfaces of the entodermal branches and near the middle of fetal life—about 18 weeks after conception when the fetus weighs from 300 to 350 gm.—the capillaries begin penetrating the heretofore continuous lining of the entodermal wall. Small knuckle-like capillary loops push aside adjacent cells and come to lie in direct contact with the lumens. Much of their surface is exposed to the potential air space.

This capillary penetration progresses rapidly after it once begins. It is accompanied by the elaboration of elastic fibers. The simultaneous growth of elastic fibers and capillaries is responsible for the gradual differentiation of alveolar ducts and alveoli. Eight to 10 weeks after penetration begins, the capillary bed in contact with the potential air space is sufficiently extensive to permit the fetus to oxygenate its own blood if delivered at this time. One of the main reasons why the end of the 28th week of gestation, when the fetus weighs about 1,000 gm., generally marks the dividing point between viability and nonviability is because only then does the number of blood vessels in direct contact with the potential air space permit adequate transmission of oxygen to the blood. The longer the fetus remains in the uterus, the more extensive vascularization becomes and the more readily oxygenation is accomplished.

The lung is anatomically the same in the mature fetus who has never breathed air as in the infant who has been breathing for several hours except for the caliber of the alveolar ducts and alveoli. Throughout intrauterine life lumens are present in all portions of the pulmonary tree. Under normal circumstances they are relatively small, but a definite pattern is visible and the inner surfaces of the walls are never completely approximated except as a result of postmortem degeneration. The lung is entirely ready in a mature fetus to permit transfer of oxygen into the blood in the pulmonary circulation immediately after birth and to function as adequately as it will at any age.

The respiratory center in the brain differentiates very early, and respiratory movements are among the first movements to be observed in the fetus. In a study of the lungs made several years ago on normal fetuses delivered by hysterotomy, I found it was necessary to compress the trachea in fetuses as small as 100 gm. if inspiration of air was to be prevented after they were removed from the uterus. There is no evidence that immaturity of the respiratory center is ever responsible for failure to breathe.

In the study just mentioned, Davis and I [1] showed that radiopaque material introduced into the amniotic fluid was invariably drawn into the lungs of fetuses weighing less than 400 gm. and that it was also inspired at term.

[1] Davis, M. E., and Potter, E. L.: Intrauterine Respiration of the Human Fetus, J. A. M. A. **131**: 1194 (Aug. 10) 1946.

(These were the only groups studied.) Although a few investigators still believe that any intrauterine respiratory activity is pathological, we demonstrated to our own satisfaction that respiratory movements occur normally during intrauterine life. There is no denying that anoxia can be responsible for excessive inspiration of amniotic fluid, but anoxia causes an abnormal type of activity and is responsible for much greater dilatation of alveoli than ever occurs under ordinary circumstances.

The normal infant at the time of birth has a normally functioning respiratory center, has lungs with a rich capillary bed ready to oxygenate its blood, has lumens in the pulmonary tree that are ready to be distended by the ingress of air, and, unless some pathological process prevents, its intrauterine respiratory activity will be directly continued into its extrauterine life. A normal infant will never fail to breathe after delivery.

The word "resuscitation" as used by most persons seems to imply that respiration is a response to some kind of a trigger mechanism and that to resuscitate an infant they must pull this trigger by spanking or administration of drugs or rocking or inflating the lungs or some other procedure.

Resuscitation of adults consists of supplying oxygen by periodic insufflation of the lungs until the effects of whatever has been responsible for apnea has worn off. Resuscitation of the newborn infant consist of exactly the same thing. If the infant does not breathe at birth, oxygen must be supplied until the effect of whatever was responsible for its failure to breathe has ceased to act. The most satisfactory resuscitation consequently is accomplished by whatever method of introducing oxygen into the lungs most closely simulates the effect that could be produced by the infant's own efforts. The periodic introduction of an oxygen-rich gas directly into the trachea at a pressure sufficient to permit it to pass from the bronchi into the alveoli but sufficiently controlled to prevent rupture of any part of the lung by hyperdistention is the ideal.

REASONS WHY INFANT DOES NOT BREATHE

There are many reasons why an infant does not breathe, but by far the commonest are cytotoxic states of the respiratory center caused by anoxia, by depressant drugs, or by other toxic states in the mother. Some of these effects are temporary, and it is to provide oxygen until such time as that effect shall have passed that resuscitation is undertaken.

The mouth and the pharynx of the infant are usually full of amniotic fluid and mucus at birth, and these are usually inspired without ill-effect with the first breath. Unless an infant has been anoxic for a prolonged period before birth so that its alveoli have been distended by debris from the amniotic fluid, there will be no direct mechanical obstruction to breathing. Even then the effect on the brain of the anoxia that was responsible for excessive intrauterine activity is more important in failure to breathe than is the direct effect on the lungs. Plugging of a bronchus with mucus sufficient to interfere with establishment of extrauterine respiration is of almost unknown occurrence. Except in malformations or the more massive intrauterine pneumonias, a local disturbance in the lungs is almost never responsible for immediate postnatal apnea. All infants who do not breathe are ill; this must never be forgotten when treatment is instituted.

INTRAMUSCULAR USE OF DIMENHYDRINATE (DRAMAMINE) TO CONTROL POSTOPERATIVE VOMITING

Daniel C. Moore, M.D., L. Donald Bridenbaugh, M.D., John C. Green, M.D.
Vincent F. Piccioni, M.D., Pliny A. Adams, M.D.
and
Carl A. Lindstrom, M.D., Seattle

In November, 1951, we presented a paper in which it was stated that intramuscularly administered dimenhydrinate (Dramamine) seemed to reduce postoperative vomiting by approximately 50%. At that time it was stated, "It is hoped that further interest in this subject will be stimulated so that an extensive evaluation of the drug may be made." [1] Certain objections have been raised regarding the validity of the conclusions of our preliminary report and those of others describing the efficacy of dimenhydrinate for control of postoperative vomiting.[2] The main objections that have been raised were that (1) if the study method described in this article is to be significant, many thousands of cases must be reported, and (2) no "placebo" control series appeared. Other minor objections included the facts that (1) there was no note made of the amount of vomiting past 50 cc., which was set as criterion for vomiting; (2) the character of the vomitus, i. e., bile-stained or clear, was not described; (3) our previous article did not specify in enough detail how the study was carried out nor did it note the personnel involved; and (4) the possibility of prejudice and bias could have existed. These are all justifiable criticisms—ones that we hope are satisfactorily answered by this report, which includes a review of the use of dimenhydrinate in 8,849 cases as well as the results of a "double-blind" series of 394 cases in which neither the anesthesia department, the floor nurses, nor the surgeons at our institution knew if the solutions injected did or did not contain dimenhydrinate.

METHOD OF STUDY

The over-all incidence of vomiting for nine general classes of anesthetic techniques most frequently used at

---

From the Department of Anesthesiology, the Mason Clinic.

This study was made possible through the cooperation of G. D. Searle & Co., Chicago.

[1] Moore, D. C.; Anderson, L.; Wheeler, G., and Scheidt, J.: The Use of Parenteral Dramamine to Control Postoperative Vomiting: A Report of 1192 Cases, Anesthesiology 13: 354-360, 1952.

our institution was established by a six months' study of cases, during periods in which dimenhydrinate was not employed (table 1). This served as a control. Then a standard method of administration was established, termed the "dimenhydrinate routine," by the hospital staff. This consists of administration of 1 cc. (50 mg.) of dimenhydrinate intramuscularly on call to surgery, of 1 cc. (50 mg.) intramuscularly on return from surgery, and then of 1 cc. (50 mg.) intramuscularly every four hours for four doses. All patients who were to have an anesthetic regardless of the magnitude of surgery and who fell into the nine general classes of anesthetic techniques listed in table 1 received the "dimenhydrinate routine." It is emphasized that no attempt at selection of cases was made, nor were there any alterations in the routine use of opiates preoperatively and postoperatively. The only time the dosage of dimenhydrinate was changed was for children under 5 years of age, in which instances the dosages were reduced to 25 mg. The only cases in which it was purposely omitted were in children under 1½ years of age and in tonsillectomies. Patients subjected to tonsillectomies were not included in this study, since they were admitted to the hospital the morning of the scheduled operation and dismissed that afternoon; therefore, the preoperative visit as well as postoperative follow-up was virtually impossible.

All patients in these series were seen before operation, within the first 24 hours after operation, and daily thereafter. They were questioned as to whether or not they had vomited and asked to estimate the amount and to describe such things as the character of the emesis, its color, and its viscosity. Their responses were checked against the nurses' notes and comments as well as observed contents of the emesis basin and stains on the bed linens. Vomiting was defined as the emesis of any material that measured 50 cc. or more in volume. Spitting up of mucus or bile was not considered vomiting in this study unless it exceeded this stipulated amount. The Chicago key-sort anesthesia card was used for tabulation. With this general standard procedure for the study of dimenhydrinate established, two series of studies were conducted in the following manner.

Dimenhydrinate Series.—For five years (1949 to 1954), except for the periods during which control series and the double-blind series were conducted, a solution known to contain 50 mg. of dimenhydrinate per cubic centimeter of solvent was given by the routine dimenhydrinate technique to 8,849 patients. These patients were observed by both the attending staff and the residents of the anesthesia department as well as the nursing staff. The greater majority of patients in this series were not told that they were receiving a drug to control postoperative vomiting.

Double-Blind Series.—Although 8,849 cases would seem to be a significant number of cases, it was felt that to rule out all possibilities of prejudice a double-blind study should be conducted. Arrangements were made, therefore, to prepare 20 numbered boxes, each containing 25 5-cc. rubber-stoppered vials; the number of the box in which it was originally received appeared on the dimenhydrinate label of each vial. The identity of the solution in each container remained unknown to any of the hospital staff until completion of the study and tabulation of the results.

From Aug. 1, 1954, to Oct. 10, 1954, these solutions were administered to the patients by the established routine method, care being taken to see that when a patient was started on one number that all the injections given the patient were from a bottle containing that specific number. As a matter of fact, no hospital floor had more than one box at any one time. The boxes containing the bottles of solution were passed out to the surgical floors of the Virginia Mason Hospital at random, no effort being made to place specific numbers on the same floor; for example, the even numbers were not given to one floor and the odd numbers put on another.

The patients were visited by the residents and staff physicians of the anesthesia department as stated above. After the first week of the study one of the attending staff anesthesiologists (D. C. M.) did not participate actively in these visits to the patients. His main part in the study was its supervision and writing the report. He was the only one who had participated in the first study, and it was felt that this would eliminate any criticism of bias of the report. Therefore, eight different physicians visited the patients to check whether or not emesis had occurred. They charted on the key-sort cards the number of the box from which the ampul was taken and the amount and the character of the vomiting. The charts were not reviewed and the incidence of vomiting with each number was not determined until the entire series was terminated.

TABLE 1.—*Control Series in Study of Dimenhydrinate*

which the dimenhydrinate routine was used and each cubic centimeter of the solution known to contain 50 mg. of dimenhydrinate, the incidence of vomiting was 13.0% (table 2).

After the results obtained with the specially labeled material prepared for the double-blind series was tabulated, the key to the identity of the solution in each vial was received. Decoding of the tabulated information revealed the following results: 1. Of the 199 patients who received the solvent only by the routine method, 48 vomited, a percentage of 24.1 (table 3). 2. Of the 195 patients who received this routine with solutions containing dimenhydrinate, only 26 vomited, a percentage of 13.3 (table 4).

When a patient in this series vomited, he almost invariably vomited an amount far in excess of the 50 cc. volume, i. e., 200 to 500 cc. Most patients were permitted liquids on return from surgery as desired and food as tolerated. There was no correlation between the character of the vomitus and the amount vomited.

COMMENT

The significance of this report lies in the fact that the double-blind study (tables 3 and 4), which was conducted in such fashion that no one in the hospital knew what the bottles contained, paralleled so closely the results of the control series (table 1) and the series in which it was known that the dimenhydrinate, 50 mg. per cubic centimeter, was injected (table 2). In the control series (table 1) the incidence of vomiting was 22.6%, while that in the double-blind study (table 3) was 24.1% when solutions that did not contain dimenhydrinate were injected. In the series of 8,849 cases in which dimenhydrinate was injected, the incidence of vomiting was 13.0%. In the double-blind study it was 13.3% when solutions containing 50 mg. of dimenhydrinate per cubic centimeter were administered. These figures are in close agreement and seem to be well within the limit of experimental error.

Perhaps it could be argued that the ideal method for this study would have been to give the solutions only to patients receiving ether as the primary agent, since the incidence of vomiting is high following its administration. Also, it might have been better had all the patients in the study had the anesthetic administered by one anesthesiologist and after surgery been returned to only one ward where specially instructed nurses were in charge. However, we do not believe this is true, because if a drug is to be of value in postoperative vomiting it must control the over-all incidence of postoperative emesis irrespective of the anesthetic method or agent used and the ability of the personnel involved. It is our feeling that there are so many variables that may result in vomiting that such a narrow study might not be as significant. Also, it has been our experience that patients, who have not had the benefit of preoperative preparation and who have received either a regional nerve block or a small amount of thiopental (Pentothal) often vomit, although these techniques are thought to be associated with a low incidence of vomiting.

The statistical significance of the results obtained in this study was evaluated by statisticians at the University of Washington as follows[3]:

> The data on the effectiveness of the use of Dramamine for postoperative vomiting were analyzed by means of the chi-square test. For the main group of trials, N=10,351, the probability was less than one in a hundred million that the drug did not significantly reduce the incidence of postoperative vomiting, i. e., $P<00000001$. In the "double-blind" trials, N=394, the probability was P=.009, or approximately nine chances in a thousand that the Dramamine was not effective. Since no difference in percent vomiting (22.6 vs. 24.1) was noted between the control groups, and likewise no differences between the treated groups (Dramamine, 13.0 vs. 13.3), the results were then combined. The combined data indicate that the chance that the Dramamine is not effective is less than one in a hundred million.

In the tables it will be noted that the primary anesthetic agent is the one under which the anesthetic procedure was classified. By primary agent we mean the agent used to obtain and maintain relaxation during the surgical procedure. Not uncommonly, we induce anesthesia with

---

3. Bennett, B. M., and Pyke, R.: Personal communication to the authors.

sodium thiopental when we intend to use ether or cyclopropane as the primary anesthetic agent. A dose of 0.25 gm. (250 mg.) is seldom exceeded. If a procedure lasts over one hour, the thiopental probably has been detoxified by the end of the surgical procedure, so that it seldom has an influence on the postoperative period. With sodium thiopental, induction is smooth and much of the anoxia of induction, which may influence vomiting in the postoperative period, is avoided. However, since thiopental has been used as an induction agent equally in both the control and the dimenhydrinate series, its effect should not influence the results.

No tissue necrosis has occurred after the parenteral administration of dimenhydrinate. Since it belongs to the class of antihistaminic drugs, side-reactions might be expected to occur in some patients. To date, we have seen no reactions other than an occasional case of drowsiness. Because of this, some physicians may question the dose of preoperative and postoperative medication that should be used since a synergistic action may possibly occur. However, while this study was conducted, we did not vary the usual premedication dose of morphine, scopolamine, or a barbiturate.

SUMMARY

In this study dimenhydrinate (Dramamine) was given to 9,243 patients to control postoperative vomiting. In 394 of these cases a "double-blind" study was run to rule out personal prejudice or bias. The study conclusively proves that at the Virginia Mason Hospital the parenteral administration of dimenhydrinate has reduced the incidence of postoperative vomiting by approximately 50%.

1118 Ninth Ave. (1) (Dr. Moore).

SPREAD OF MAMMARY CARCINOMA

Philip B. Price, M.D., Salt Lake City

Cancer probably begins in some minutely localized spot, in a little nest of cells, possibly in a single cell, or, as some believe, multicentrically in a limited area. These abnormal cells multiply, gradually overcome the restraining influence of surrounding cells and tissues and the regulating forces that govern normal cells, push their way into new territory, and begin their lawless career. The optimum generation time of cancer cells is a matter of only a few hours. Two cells become four, four become eight, and so until in time there is a solid mass of millions of cells. As the lump grows, it does not gently push other structures aside, as a benign tumor does, but it infiltrates, invades, destroys, and replaces adjacent tissue. Sometimes this process works to the disadvantage of the tumor, for it may block its own blood supply and become necrotic at the center. This extension does not take place equally in all directions. The tumor grows most rapidly along lines of least resistance. Tumor cells in stroma are somewhat like soldiers trying to advance through a dense jungle. The going is tough and slow unless they strike an open trail; then they are able to stream rapidly along. The trails of the breast are the lymphatic vessels. When tumor cells invade a lymphatic vessel, they can progress more rapidly in the form of a solid cord of cells.

METHODS BY WHICH CELLS SPREAD

But extension of mass-growth, or proliferation along lymph channels, is not the only method of spread. Tumor cells also migrate. Most of us have erroneous, unrealistic concepts of tumor cells because we are used to seeing them through a microscope in fixed, stained preparations. Those rigid, dead, brightly colored cells are no more like living functioning cells than pickled cadavers in the dissecting room are like living people active in homes and places of business. A living cell is colorless; it breathes, eats, excretes, moves, and reproduces. It may elaborate complex and potent products. Some malignant cells are capable of ameboid movement. Like white blood cells, they can work their way through the delicate endothelium of lymphatic vessels and even, though with more difficulty, through the stronger walls of the blood capillaries. In the lumen of these vessels, independent malignant cells get swept along by the blood or lymph stream, or perhaps a small clump of cells will be slowly milked along the narrow channel. Sooner or later they reach a permanent lodging place. There, if conditions are suitable and nourishment is adequate, they multiply and form a new colony.

The lymphatic drainage of the breast is rich and replete with plexuses, so that the direction of spread of malignant cells through these channels is understandably unpredictable and fortuitous. Drainage is generally toward the skin surface. There a subcutaneous plexus of lymphatic vessels permits the cells to be carried in almost any direction. These migrations may require months or years. Periods of quiescence or colonization are followed by fresh migrations. Satellite nodules are commonly observed in the vicinity of advanced tumors, or malignant nodules may appear nearby one or two or three years after mastectomy. They are commonly referred to as "local recurrences"; actually, they are macroscopic growths from microscopic extensions that were already present but not removed at operation.

The main lymphatic trunks that converge toward regional lymph nodes provide another common method of spread of breast cancer. From the mammary gland, often by way of the subareolar plexus of lymphatic vessels, this spread of metastases occurs, superiorly toward the axilla, medially toward the mediastinum or the other breast, and inferiorly toward the abdomen. To reach the axillary nodes, some lymph channels obviously must pierce the pectoral muscles that intervene; to reach the internal mammary nodes, they may penetrate the inter-

costal structures; to reach the paravertebral nodes and diaphragm they traverse the rectus fascia and underlying muscles. Lymph-borne tumor cells reach a lymph node by way of its afferent vessels. Malignant cells lodge in the subcapsular plexus of the node where they multiply and slowly invade to node proper. In time they may destroy the node and replace it more or less completely with a mass of tumor cells. When ultimately the cancer cells reach the efferent lymph vessels of the involved node, some of them may travel further seeking new fields of conquest. Dr. Herbert Davis[1] has shown that in the invasion of axillary and other regional nodes, carcinoma may bypass some nodes while invading others.

B

Fig. 1.—Diagrammatic representation of impalpable extensions of mammary carcinoma. *A*, a degree of spread that still permits total excision. *B*, a degree of spread that precludes complete removal by classical radical mastectomy.

Another method of spread of breast cancer is by way of the blood stream. This probably occurs more frequently than has been thought. However, according to Boyd,[2] "tumor emboli are not synonymous with metastases. Tumor emboli in the lungs often die out, as M. B. Schmidt showed many years ago. They become coated with fibrin, and fail to develop into tumors." If, in two animals with the same type of mammary tumor, the lesions are massaged and one animal is killed soon after, the lung capillaries will be found to be stuffed with tumor cells, but the other animal, killed some months later, will show only a few metastases, indicating that most of the emboli have failed to develop. Some malignant emboli do become tumors, however, as shown by bone, lung, and brain metastases frequently observed in late stages of the disease.

Still another method of tumor spread is an accidental and tragic one. Cancer cells can be successfully transplanted to new areas by the surgeon at operation. Washings from instruments and the operative wound have been shown on occasion to contain cancer cells. Hence the rationale of *thorough irrigation of these wounds* before closing them. An instance has been reported of cancer developing in the thigh at the donor sight from which a skin graft was taken to cover the chest wound. In the treatment of breast cancer it is of utmost importance that the physician and surgeon should understand the mechanism of spread and recognize the probable extent of spread in patients. Unfortunately, that is not always the case. Even the original lesion may remain undiscovered, or be misdiagnosed, until hopeless extension of the malignancy has already occurred.

DETECTION OF CELLS

It should be kept in mind that the surgeon, however conscientious and skillful he may be, is able to detect only the gross spread of the disease. Beyond the limits that can be seen or felt are extensions that can be demonstrated by the microscope. The more experienced and zealous the pathologist, the wider the zone of extension that he can demonstrate. A recently reported investigation[3] consisted of a restudy of the axillary nodes of 30 patients with carcinoma of the breast that on routine examination had been reported uninvolved. The investigators made serial microtome sections of these nodes and studied every other section systematically—a painstaking piece of work. They found carcinoma cells in the nodes of one-third of the cases previously reported negative. The utmost limits of spread of malignancy and the scattered migrating cells and microscopic tumor emboli lie beyond the ken of the best pathologist. There is no way to detect them. This point is illustrated further by figure 1. The first diagram, *A*, represents a palpable mammary carcinoma that seems to the surgeon to be localized within the breast, an opinion that might well be confirmed by gross and microscopic examinations of the pathologist. However, in a proportion of such cases, *spread of the malignancy has in fact already occurred*, though not to such a degree but that radical mastectomy will remove all of it. The second diagram, *B*, shows another hypothetical case in which the surgeon and pathologist find involvement of a few axillary nodes. It is hoped that radical mastectomy will remove the entire malignancy en masse. But here again, at least in many such instances, the actual spread has gone beyond the limits of the classical operation and in consequence the most distant extensions are not excised. This concept that actual spread nearly always exceeds detectable spread is so important for a clear understanding of ra-

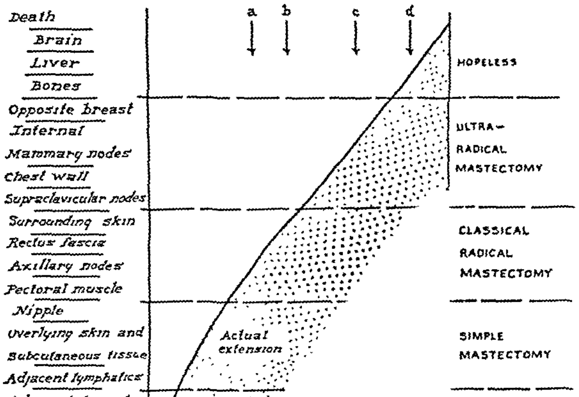

Fig. 2.—Diagrammatic representation of the difference between detectable spread and actual extension of breast carcinoma (ordinate) in relation to time (abscissa) and the adequacy of surgical attack at various stages, as when (*a*) patient discovers lump and visits doctor; (*b*) patient is delayed in reaching surgeon; (*c*) tumor is still older; and (*d*) too long delay makes case hopeless.

tional treatment and prognosis that I shall illustrate it in another way. Figure 2 is a schematic representation of the progressive spread of mammary carcinoma with the passage of time. Imagine a hypothetical patient who discovers a lump in the breast by accident and goes without delay to her physician (position *a*). Physical examination shows the tumor to be localized in the breast. Actually, however, the cancer has been in existence for an indeterminate length of time and has been spreading insidiously. By the time the original lesion is large enough to attract attention, the actual limits of extension may have passed beyond the limits of local excision and even simple mastectomy may not ensure complete removal. Now assume that the tumor is not discovered so soon and that there has been delay in the patient reaching the surgeon (position *b*). By the time of operation, the cancer will really have been present, let us say, for one or two or three years. Gross spread is still limited to the site of the original lesion, but the actual spread is much greater, so that by now radical mastectomy is necessary for extirpation. Or, suppose the tumor is older still (position *c*). The same principle holds. Physical examination at this stage shows metastases in the axilla, but the actual limits of spread, in ways already discussed, is much wider, so that a very extensive surgical dissection and excision will be required to offer even a hope of complete removal of the malignant growth. If there is further delay (position *d*), the case becomes hopeless.

COMMENT

It is not inferred, of course, that there is any uniformity among breast tumors as to rate of spread or the order in which nodes or other structures become involved. On the contrary, there is tremendous amount of variation. The important point is that every cancer of the breast begins as a localized lesion that spreads in the course of time, first insidiously and impalpably and then grossly and detectably. If the diagnosis can be made in what is, for that particular tumor, an early stage, complete excision and cure may be possible; but if an advanced stage has been reached, whether rapidly or slowly in terms of years, even radical operation will not remove all of the malignant extensions. We err if we concentrate on the gross extent of the disease and ignore the impalpable spread, the limits of which can be only imperfectly detected even by the pathologist. The concept illustrated by these figures has helped me to understand why classical mastectomy offers only 70% 5 year clinical "cure" when the cancer is limited grossly and microscopically to the mammary gland and only 30% 5 year clinical "cures" when there are demonstrable axillary metastases; why 10 year survival rates are always less favorable than 5 year survival rates; why more radical operations give better results than less radical; why patients without demonstrable axillary metastases have a better prognosis than those with axillary involvement; why the outlook is better if only some of the nodes are involved than if all or nearly all of them are cancerous; why results are improved by thorough, meticulous, radical dissections; and why tumors located in the medial hemisphere usually have a relatively poor prognosis. This concept points up the intrinsic limitations of "ultraradical" surgery and radiation therapy. In the light of this concept, Haagensen's and Stout's criteria of inoperability take on fresh significance.

CONCLUSIONS

The only hope for cure of mammary cancer at the present time is to remove or destroy the entire malignant growth, including its most distant and elusive extensions and metastases. Every device that contributes to the accomplishment of that purpose will improve prognosis; hence the need for early diagnosis, prompt radical surgery, and, in appropriate cases, supplementary irradiation.

CRASH AND LIVE—NEED CARS KILL MORE SOLDIERS THAN GUNS?

Col. Don S. Wenger, U. S. A. F.

During the Korean war only half of the hospitalized casualties were the result of enemy action. During this same conflict, more Americans were killed in the United States in automobile accidents than were killed in the war.[1] The automobile is the military establishment's and the nation's greatest killer. An American is injured every 24 seconds and one is killed every 14 minutes in a traffic accident.

Because of the age group with which we deal in the military services we are concerned with a segment of population that has no aged, inactive, sedentary part; all drive and drive a great deal. One might then expect a considerably increased automobile injury and death rate in the armed forces. Adjusted for male groups of comparable ages, the military service has about 30% more fatalities due to auto accidents than do civilians.[2] The 2,000 deaths, the 22,000 injuries, the 70 million dollar bill to the military services for injuries in these accidents, and the military loss of almost one-half million man days, all due to automobile accidents in 1954, show that we do have a tremendous problem.

To prevent injury we must know something about the mechanism that produces the injury. Quite simply one may say that as in falling from a tall building it is not the fall but the sudden stop at the bottom that does the harm, so it is not necessarily the motion of the car that kills; it is the sudden stop your body undergoes. This sudden stop generates what are called decelerative forces. These forces are measured in multiples of the pull of gravity. A force equal to the pull of gravity is called a g of force. It follows then if the force that stops

[2] Allen, A. W., Jr.: Personal communication to the author.

the forward motion of your body is three times the pull of gravity, it is a 3 g deceleration. Detailed studies on this problem of decelerated forces have been made. Repeated exposures to 35 g without harm and peaks of 57 g with no observable damage are reported. Some Air Force men have undergone over 4 tons of sudden stop pressures with no more than transient physiological effects. An appalling fact is that in most automobile accidents the decelerative g forces are in the neighborhood of 25 g or below, well within the limits easily tolerated by the human body when it is properly supported and restrained. We must then accept the fact that, with some attention to engineering and to support and restraint of the body, fatalities in automobile accidents would be sharply reduced.

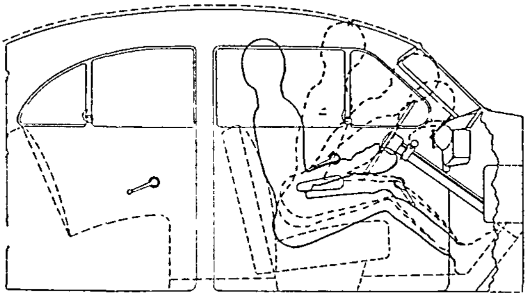

Fig. 1.—Kinematics and hit locations for an adult seated on the right side of the front seat. In a crash with the car moving only 7 mph, and with 1.5 g, the occupant's head struck the car roof in 0.17 second, the rear-view mirror in 0.23 second, and the instrument panel in 0.3 second.

HAZARDS

Studies done with dummies in controlled automobile crashes have revealed some interesting facts (fig. 1). When moving at a speed of only 7 miles an hour and with decelerative forces of but 1.5 g, the dummy, weighted to behave like a human body, flew upward and forward. Its head struck the car roof in 0.17 second; in 0.23 second it had hit the rear-view mirror, and in 0.3 second had come in contact with a third hard surface, the instrument panel.[3] Observations made by the Indiana state police on the part of the car that caused fatal injury in a series of accidents are another facet of the study of how and where we get hurt in car crashes. They have shown (fig. 2) that doors and framework are the most lethal part of a car.[4] A close second to these structures are objects outside the car against which the ejected occupant is thrown. Regardless of the severity of accidents, more occupants sustain moderate through fatal injuries by being ejected than by remaining in the automobile.[5] It has been reported that 1 out of 10 auto crash fatalities result because doors pop open and the victim is thrown out of the car.

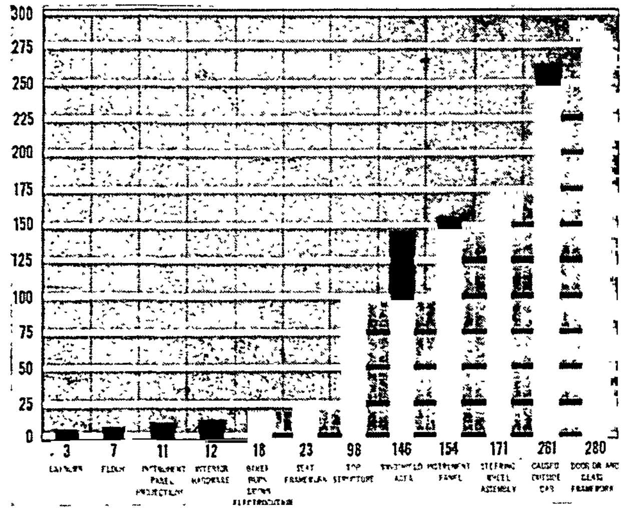

Fig. 2.—Causes of fatal automobile injuries.

A study of the hazard of ejections shows (fig. 3) that *moderate to fatal injuries increase significantly, and in* some cases more than double, when ejection from the car occurs.[5] It has been reported that when front doors opened in accidents, one out of every three occupants was completely ejected from the car. The statement has also been made by engineers studying the fatal accidents in Indiana in 1951 that two-thirds of them were survivable if the design of the car had been better.

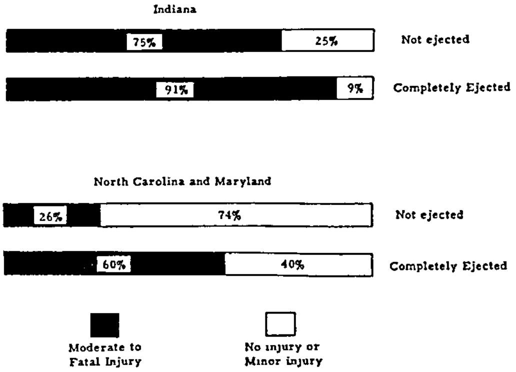

Fig. 3.—Injury as related to complete ejection from automobile.

A graph of the number of injuries to various parts of the body (fig. 4), giving the 1952 experience of one of the military services, shows over 8,000 minor injuries that required first-aid treatment only. After ruling out this group of injuries, it is significant that the next largest group, 2,409 cases, were head injuries. More head injuries occurred than the total of the next two most common injuries (lower extremities 1,400 and trunk 943). Although multiple injuries are often seen, it is nevertheless common to see a fatality that is relatively unscathed except for head injuries. The force required to seriously injure a head may vary a great deal depending on the area through which the force is absorbed and the time during which the force is applied. In demonstration of the variations caused by changing the size of the area involved, the following rough estimates are cited: 600 in.-lb. of force will fracture a skull struck by a firm flat surface; a baseball bat will break a head with only 85 in.-lb. of force; and on a sharp 90 degree angle, such as the edge of a rear-view mirror, a skull will fracture with only 50 in.-lb. of force.

PROTECTION DEVICES

Protection from crash injuries may be local or general. Local protection is the guarding of parts frequently injured. An example is the crash helmet that a flyer or an automobile racer uses. A serious problem in the use of local protective devices is getting the motorist to use the device. The jet pilot has been educated from the beginning of his training that a helmet will keep him from getting his brains scrambled on the canopy of his plane if he hits rough air or crash lands. No one has yet educated the motorist in methods of living through accidents. The next step toward safety in design is education of the driving public to recognize the need, to realize the possibility of protection, and to demand these changes that will protect him.

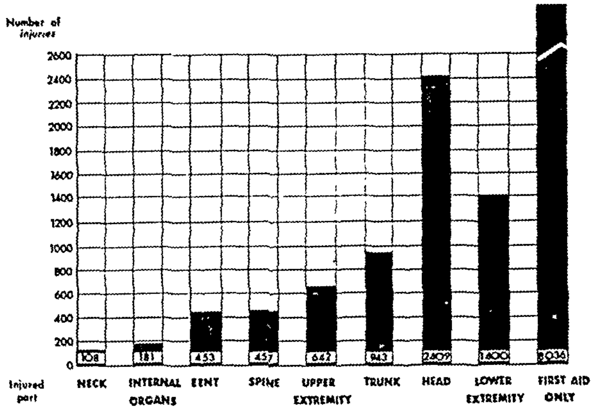

Fig. 4.—Frequency of injury to various parts of the body (1952 experiences of one of the military services).

There are several items of equipment and design that would increase a motorist's chance of survival of an accident. The first, simplest, and perhaps, under present circumstances, the most effective procedure would be to secure the passengers within the vehicle with a safety belt. The passengers then would wear the vehicle much as a knight of old wore a suit of armor. Forces that a safety belt can control are surprising. In a 50 g deceleration run at Muroc Lake, Calif., Oscar, a dummy used in some tests, broke his restraining harness. He flew through the protecting shield and bounced down the track, sliding to a stop 789 ft. away. Investigators at Cornell University, Ithaca, N. Y., believe that a safety belt will prevent about one-half of the fatalities in automobile accidents. A simple lap belt can be made even safer by adding a chest strap that will prevent bending over the lap belt and hitting the head on the dashboard. As long as there are car doors that pop open and windshields that do not, a safety belt is needed to restrain the car's occupant from flying about within the car or getting ejected from it.

If the decelerative forces generated by an accident are absorbed through a large surface much less damage results than if the same forces are absorbed through a small surface. For example, if a body falls flat on its back into soft earth it may undergo a deceleration of 150 g but have pressures of only 30 lb. per square inch on the surfaces involved. On the other hand, if the 150 g deceleration is absorbed entirely by a few square inches on the top of the head, the pounds per square inch will go to astronomical figures and severe injuries will result. Padded panels and crash pads on the steering wheel and other structures serve to increase the area over which decelerative forces are applied. If one can reduce the sudden high peaks of decelerative force the probability of injury is also greatly reduced. If deceleration is over a greater distance and for a longer time the peaks of force are reduced. Soft pads serve to increase by a significant degree the distance through which deceleration is accomplished, and thereby not only increase the area of the force-absorbing surface but reduce the peaks of force that must be absorbed.

Another method of reducing the sudden severe peaks of decelerative forces is the construction of a frame that will progressively disintegrate (fig. 5) and absorb g's during its disintegration. The principle involved is that the frame collapses with the stress necessary to decelerate it with a certain predetermined number of g's. The greater the speed at impact the more frame collapses and the more time is consumed in deceleration, but never does the force rise above the predetermined decelerative force for which it is designed. Since this is true, the passengers in the uncollapsed portion remain relatively safe, for never are they subjected to sudden high peaks of deceleration that will tear loose and throw them about. Passengers in the rear of a vehicle designed in this fashion when crashing at 60 mph are never subject to a greater decelerative force than when crashing at 20 mph. The only factor that changes is the time during which they are exposed to this force. This energy-absorbing construction can, of course, be extended to parts of the construction as well as used on the main frame. Examples would be a hydraulic or collapsible bumper that would absorb energy and decelerate the car gradually. A telescoping steering wheel or one perhaps of the weak-link principle of construction that would collapse under certain predetermined forces would be another example of energy-absorbing construction. Many vehicles now have a steering wheel that will deform under pressure.

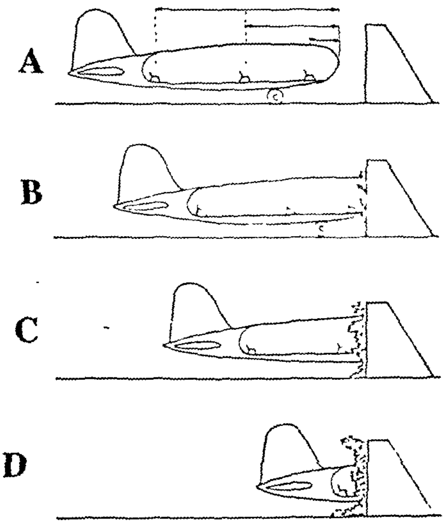

Fig. 5.—Progressive disintegration of the frame will reduce the sudden severe peaks of decelerative force. *A*, mock-up of a fuselage. *B*, crash at 20 mph with 4 ft. of structural collapse. *C*, crash at 40 mph with 16 ft. of structural collapse. *D*, crash at 60 mph with 36 ft. of structural collapse. Maximum decelerative force in *B*, *C*, and *D* is 3.3 g.

This is also energy-absorbing construction that removes a lethal hazard from the driver.

A pop-out windshield is another device to remove a hard, dangerous surface from the path of flying bodies. It may also prevent a cut throat.

Whiplash injuries of the neck are common results of being hit from behind. Sudden acceleration whips the head backwards, automatic correction is put into action by the body, and, because the sudden acceleration stops just as suddenly (becoming deceleration), overcorrection occurs and the head and neck lash forward. This whip-like action sprains many necks. To raise the back of the seats to a level that would support the back of the head and neck would prevent most of these injuries for the acceleration would not start the body's compensatory motion because the support of the back of the seat would substitute for the neck muscles support. For this reason, overcorrection would not occur and the whipping action would be so minimized that injury would be rare.

SUMMARY

The military services sustain an important loss in lives, hours, and dollars as a result of automobile accidents. Injuries usually result from specific causes. Remedies may be just as specific and simple. Reduce the high peaks of decelerative forces, enlarge the area that absorbs these forces, and restrain the occupants of automobiles so they do not fly around within or outside the car and a majority of the fatalities and injuries would never occur. Possible mechanisms to obtain these results are safety belts, a progressively disintegrating frame, and energy-absorbing construction of various lethal parts of the vehicle such as steering wheels, instrument panels, windshields, and seat backs. A shock-absorbing bumper, either hydraulic or collapsible, padded panels, and pop-out windshields are possible examples of such construction. A high-backed seat would reduce materially the whiplash neck injuries. If properly packaged for survival you can crash your car and live.

INTRAVENOUS CHOLECYSTOCHOLANGIOGRAPHY

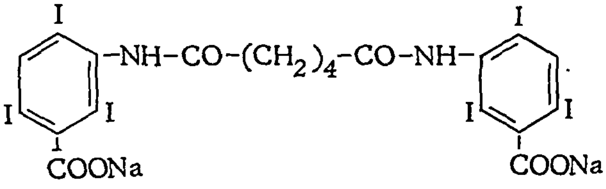
William H. Shehadi, M.D., New York

Visualization of the biliary tract in the natural or intact state has been realized in three major stages, each a milestone of progress in this field. The first stage came with the well-known work of Graham and Cole [1] in 1924 and 1925, which resulted in visualization of the gallbladder. The second stage came about a quarter of a century later through the introduction of iopanoic acid (Telepaque). While investigating this compound as a cholecystographic medium, a high incidence of bile duct visualization was observed.[2] With adequate gallbladder function, the cystic and common bile ducts are visualized in normalcy and the hepatic ducts by reflux.[3] This occurs in 70% of patients examined, or in about 85% of patients whose gallbladders can be visualized. The incidence of duct visualization in the cholecystectomized patient is low and remains more or less unpredictable. The third stage came with the introduction of sodium iodipamide (Cholografin) in this country about two years ago [4]; it had been introduced in Europe about a year prior [5] as Biligrafin. When injected intravenously, sodium iodipamide provides a reliable, rapid, and safe medium for visualization of the entire biliary tract, as demonstrated by our experience in over 200 cases. Other investigators reporting on smaller or larger series, both in this country and abroad, have arrived at the same conclusion.

SODIUM IODIPAMIDE

Intravenously injected sodium iodipamide will produce (1) visualization of the bile ducts in cholecystectomized patients and in patients whose gallbladders fail to be visualized after oral administration of a radiopaque material, due either to gallbladder disease or to faulty absorption because of disturbed function of the gastrointestinal tract and (2) visualization of the gallbladder; often, when there has been failure of visualization after use of an orally administered radiopaque material.

With six firmly bound iodine atoms in its molecule, sodium iodipamide readily opacifies the biliary tract as bile flows from the liver into the ducts. This is independent of the gallbladder's ability to absorb water and concentrate its contents. It is the disodium salt of N,N'-adipyl-bis (3 amino-2,4,6-triiodobenzoic acid), with an empirical formula of $C_{20}H_{12}O_6Na_2$, a molecular weight of 1183.35, and an iodine content of 64.32% The structural formula is:



This is a readily soluble crystalline substance, supplied in a 20 cc. ampul of a 20% solution, with a companion 1 cc. test ampul. Optimal dose is 40 cc.

PREPARATION AND INJECTION

To prepare the patient for examination administration of castor oil the evening preceding the examination and withholding of fluids for 12 hours or more for dehydra-

tion purposes may be supplemented by use of neostigmine (Prostigmin) at the time of the examination, if indicated. Failure to adequately prepare the patient may account for the apparent unsatisfactory results obtained by some workers.

Despite the very low toxicity of sodium iodipamide, cose solution, ephedrine, and oxygen tanks, should be performed on all patients prior to its administration. The ocular test should not be performed. It is unreliable and not without danger to the eye in case of a severe reaction. However, positive sensitivity tests do not necessarily forecast or indicate the occurrence of side-reactions. With a known history of allergy or a strongly positive test we recommend premedication with diphenhydramine (Benadryl) hydrochloride or chlorpheniramine (Chlor-Trimeton) maleate. An emergency set, including a number of sterile syringes, needles, 5% glucose solution, ephedrine, and oxygen tanks, should be available at all times. Warmed to body temperature, 40 cc. of sodium iodipamide is injected slowly during a period of 10 minutes. The incidence and intensity of side-reactions can be increased with acceleration of the injection rate, and vice versa. The side-reactions so far encountered (table 1) have been easy to control. Anyone who has had experience with other intravenously injected contrast mediums, especially those used in urography, should have no hesitation whatever in using sodium iodipamide. Blood pressure as determined by measurements made before, during, and after examination remains essentially unaltered. Minimal fluctuations have been noted in some cases but seem to be of no consequence.

TABLE 1.—*Side-Reactions in 200 Patients After Injection of Forty Cubic Centimeters of Sodium Iodipamide*

	Patients	
	No.	% Examined
Nausea	11	5.5
Vomiting	3	1.5
Sensation of heat	4	2.0
Flushing	7	3.5
Chills	2	1.0
Temperature	1	0.5
Pain in the arm	3	1.5
Headache	1	0.5
Allergic reaction with marked drop in blood pressure	1	0.5
Total side-reactions noted	33	16.5

METHOD OF EXAMINATION

The patient is placed in the supine position, with the left side elevated 15 to 30 degrees. Through greater comfort in this position, the patient will cooperate more freely. The ducts are equidistant from the anterior and posterior abdominal wall; therefore, no distortion occurs. Use of this position developed with our work on iopanoic acid and is equally applicable here.[6] When present, the gallbladder will be at a higher level and heavier bile will flow more readily, giving a more intense duct shadow after a fat meal, especially of the cystic, which is better visualized with iopanoic acid than with sodium iodipamide. The success of the procedure, to a large measure, depends on careful attention paid to technique and detail. Every film should be inspected by the radiologist as soon as it is developed, and the position and technique should be corrected and varied as indicated, in order to obtain optimal results.

EXCRETION

Sodium iodipamide is selectively excreted by the liver through the bile. In 90% of cases it appears in the ducts immediately after injection. In 10% of cases it is excreted entirely by the kidneys. Simultaneous hepatic and renal excretion occurs without evident liver disease and with satisfactory visualization of the biliary tract (fig. 1). The significance of this phenomenon cannot be evaluated at the present time. Further studies may prove enlightening in this respect, as well as in evaluation of this method as a liver function test. After liver excretion sodium iodipamide is eliminated by the intestines with no evidence of reabsorption.

VISUALIZATION OF THE BILIARY TRACT

Prompt liver excretion results in visualization of the bile ducts as early as 10 minutes after completion of the injection. For a study of the ducts, films should be made at 10 minute intervals up to 60 minutes, with optimal visualization occurring at 30 to 40 minutes. The gallbladder is often visualized as early as 10 to 20 minutes after the injection but usually at about two to two and a half hours. Once filled, the gallbladder examination should be completed in the same manner as after oral cholecystography (fig. 1).

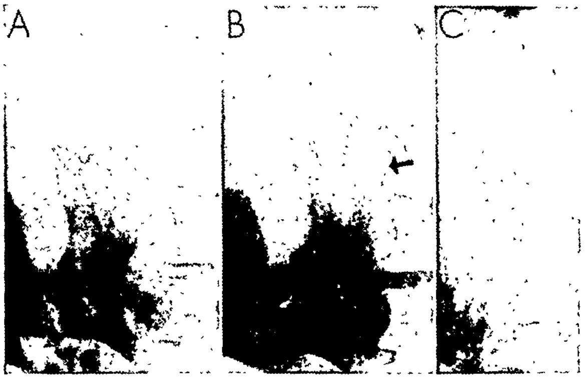

Fig. 1.—Simultaneous hepatic and renal (arrow) excretion. Early filling of normal gallbladder, with prompt response to a fat meal. Normal bile ducts. *A*, 10 minutes after injection; *B*, 60 minutes after injection; and *C*, 40 minutes after fat meal.

6. Footnotes 2 and 3.

Not infrequently, an area of decreased density is seen in the center of the gallbladder (fig. 2). This is due to slow or delayed mixing of the inflowing sodium iodipamide that, with the bile, is already present in the gallbladder. At times (table 2) the gallbladder failed to visualize with an orally given radiopaque material but was well visualized with sodium iodipamide. In some cases one or more calculi were found, while in the others the gallbladder was apparently normal. One may presume that transitory impaction of a calculus at the ampulla of the gallbladder may have occurred in some instances (fig. 2); however, this explanation does not seem tenable in the absence of calculi. Other causes are still to be found. In a cholecystectomized patient the examination should be completed in one hour; however, when there is partial obstruction at the distal end of the common bile duct a longer time may be needed because of accumulation of the inspissated bile (fig. 3). In the presence of obstructive jaundice the bile ducts can not be visualized.

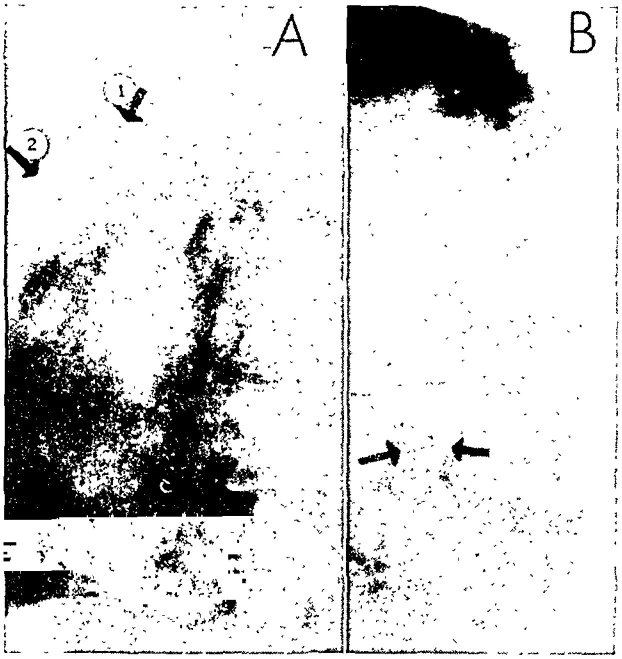

Fig. 2.—*A*, almost complete impaction of cholesterol calculus at infundibulum (arrow 1). Area of decreased radiance in gallbladder (arrow 2) represents poor admixture, with sodium iodipamide surrounding bile. This later disappears. *B*, after fat meal calculus had dropped to bottom of fundus.

* In all 81 patients there was prompt hepatic excretion with good visualization of normal bile ducts.

ANATOMIC AND PHYSIOLOGICAL CONSIDERATIONS

In order to adequately evaluate pathological changes a basic knowledge of the normal anatomy and physiology is imperative. We were confronted with this very problem in our initial work on iopanoic acid.[6] Consistent duct visualization was obtained, but there was no base line to fall back on. Duct measurements of the anatomic specimen in the cadaver and in the operating room during laparotomy were misleading because of the variety of abnormal factors involved, as compared with the absolute normal in the intact subject. After administration of iopanoic acid, duct measurements were made on the roentgenograms of several hundred normal subjects, with correction for distortion due to distance, whose gallbladders demonstrated normal function, who were entirely asymptomatic, and who had received no medication other than the iopanoic acid.

The hepatic and common bile ducts are practically of equal caliber and measure 0.5-0.6 cm. in diameter.[3] A 0.1-0.2 cm. measurement is often obtained during a phase of relaxation of the sphincter of Oddi, with rapid passage of the opacified bile into the duodenum. The tortuous cystic duct measures 0.2-0.3 cm. in diameter. These findings have been corroborated by subsequent sodium iodipamide studies.[4d] Any departure from these measurements, if constant, is to be regarded as abnormal and should lead to a search for the cause. Our recent

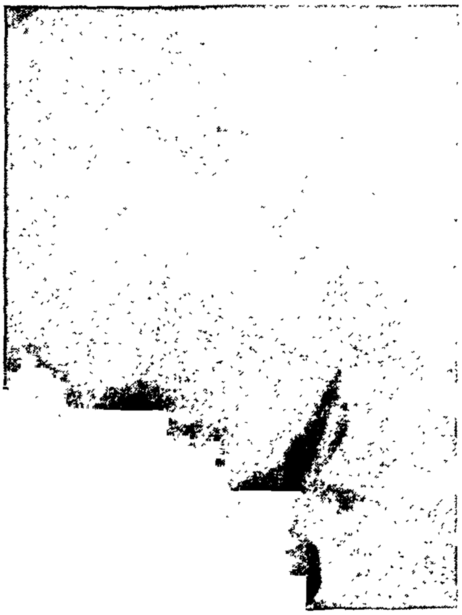

Fig. 3.—Roentgenogram made 60 minutes after injection showing marked dilatation of common and hepatic duct. Note funnel-shaped distal end of common bile ducts. Cholecystectomy had been done five years prior.

studies reveal the following causes: calculi in the ducts, strictures, stenosis of the sphincter of Oddi, growth of intrinsic tumors, or pressure from extrinsic masses.

It may seem premature to voice a definitive opinion, but our studies so far do not warrant the contention that compensatory functional dilatation of the main bile ducts takes place after cholecystectomy. When such dilatation occurs, in the absence of calculi, adhesions, or tumors, it is usually caused by stricture of the duct or stenosis at the sphincter of Oddi. It is felt at this time that further studies will warrant an impression so far gained, and proved, in many cases that often the so-called postcholecystectomy syndrome is a late recognition of preexisting, most probably gradually progressing, conditions antedating the cholecystectomy, whether or not the gallbladder was diseased at the time of the operation.

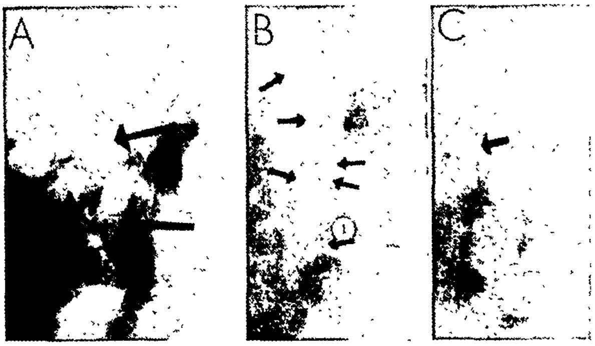

Fig. 4.—Variety of calculi in common bile duct, proved at operation. *A*, multiple bile pigment calculi and dilated duct. Cholecystectomy had been done eight years prior. *B*, multiple cholesterol calculi, with one calculus impacted at distal end of common bile duct (arrow 1), and dilatation of both hepatic and common bile ducts. Cholecystectomy had been done four years prior. *C*, large cholesterol calculus, with calcium ring at distal end of dilated common duct. Gallbladder in situ.

Intravenous cholangiography will reveal a number of pathological conditions with dilatation. The most frequent type of dilatation of the extra hepatic bile ducts is due to stenosis of the sphincter of Oddi (fig. 3). In this condition, the distal portion of the common bile duct is more or less funnel-shaped, with accompanying uniform proximal dilatation, whereas compression by tumor masses will result in corresponding deformity and, at times, irregular dilatation. Calculi are obvious by the shadow or filling defects they produce (fig. 4). In addition to the above, this method of examination has revealed a number of anatomic variations, the preoperative recognition of which is of great importance to the surgeon. Residual stump of the cystic duct, with or without calculi, and so-called reformed gallbladders have also been observed in our series.

SUMMARY

A new and safe method for rapid visualization of the biliary tract is now available. Use of sodium iodipamide (Cholografin) is indicated (1) in patients who have had prior cholecystectomy, (2) when the gallbladder fails to visualize after administration of an orally given radiopaque material, (3) when patients are unable to retain or absorb orally administered medicament because of disturbed function or disease of the gastrointestinal tract, and (4) when prompt evaluation of the biliary tract is required in the differential diagnosis of acute conditions, especially when surgery is considered. Contraindications to its use are obstructive jaundice and severe liver and kidney damage. With a history of allergy or sensitivity to iodine and to intravenously administered iodine-containing mediums, sodium iodipamide may be safely administered after premedication with diphenhydramine (Benadryl) hydrochloride or chlorpheniramine (Chlor-Trimeton) maleate. In addition, oxygen, 5% glucose solution, and ephedrine should always be available for instant use when needed.

INTRAVENOUS CHOLANGIOGRAPHY IN THE POSTCHOLECYSTECTOMY SYNDROME

John L. McClenahan, M.D., John A. Evans, M.D.
and
Paul W. Braunstein, M.D., New York

Because of its ability to demonstrate the bile ducts when the gallbladder has been resected or has ceased to function, sodium iodipamide (Cholografin) offered immediate promise in the examination of patients with digestive complaints persisting after cholecystectomy. In recent months we have examined 121 individuals with the varied symptoms of the postcholecystectomy syndrome, and we present in this paper our analysis of their intravenous cholangiograms. We offer, in addition, our observations in a control series of 46 patients who reported themselves free of symptoms after cholecystectomy.

The postcholecystectomy syndrome is a familiar and discouraging disorder characterized by abdominal pain, nausea, and intolerance to certain foods, continuing unabated after cholecystectomy. Its very name is ambiguous in its implication that the operation has caused symptoms, when, in fact, it has simply failed to relieve them; for this reason we prefer Best's[1] more accurate term, "the recurrent biliary tract syndrome." Causes for the complaint may be mechanical irritation or obstruction of the common bile duct because of stone or cystic duct remnant or functional spasm and incoordination

From the departments of radiology and surgery, the New York Hospital-Cornell Medical Center.

Read in the Symposium on Newer Contrast Media for Visualization of the Biliary Passages, before the Section on Radiology at the 104th Annual Meeting of the American Medical Association, Atlantic City, June 8, 1955.

The sodium iodipamide used in this study was supplied as Cholografin by E. R. Squibb & Sons, New York.

[1] Best, R. R.: Remaining Common Duct Stones and the Recurrent Biliary Tract Syndrome, editorial, A. M. A. Arch. Surg. 66: 581 (May) 1953.

(biliary dyskinesia) of the sphincter of Oddi. In the numerous reports on the subject may be found one point of general agreement—the importance of cholelithiasis in the initial preoperative diagnosis. Cole and Grove[2] estimate, for example, that cholecystectomy will relieve the symptoms in 95 of 100 patients if there are stones in the gallbladder but will perhaps benefit only 60% of those with noncalculous disease.

Until recently operative cholangiography has been the only reliable method of outlining the bile ducts after cholecystectomy, and with supplemental information from the laboratory we have been taught what we know of the pathology of the bile ducts and physiology of the choledochal sphincter. Oral cholangiography has sometimes been successful when the gallbladder is present and functioning[3] but is unpredictable after cholecystectomy. It is in just this situation that intravenous cholangiography gives its most rewarding results.[4]

PROCEDURE

The properties of sodium iodipamide have been frequently described[5] and need not be reviewed here. It is important that the medium should be injected slowly and the patient be as free as possible from jaundice and from drug idiosyncrasies. We have usually given the full dose of 40 cc. of the 20% solution, and as a rule we have not given camphorated opium tincture (paregoric) or any other opiate before examination. Our series of 121 patients with the postcholecystectomy syndrome included 100 women and 21 men, whose ages extended from 23 to 79 years. The common bile duct was adequately shown in 87% of the group. Three severe reactions occurred, presenting the picture of shock, with vomiting, abdominal pain, profuse perspiration, and ashen complexion. More mild reactions were observed in 25 other individuals who became nauseated, flushed, and who occasionally vomited. In every case the reaction subsided spontaneously or after administration of an orally given antihistamine. We found preliminary skin testing of little value in predicting a toxic systemic reaction to the drug.

In a clinical report to follow, the symptoms of our patients will be presented in detail and related to operative findings and cholangiograms. Every individual complained of upper abdominal pain. In many the pain radiated to the back. Some patients reported episodes of jaundice and fever. In order to simplify our statistics we have attributed symptoms to a single cause when more than one abnormality existed in any one patient. To avoid exaggerating the part played by the biliary tract we have, when the choice existed, ascribed symptoms to lesions outside the bile ducts.

CLINICAL FINDINGS

Extrahepatic Disease.—The complaints of 26 patients (21.5%) could reasonably be accounted for by concurrent extrahepatic disease. These are listed in table 1 and include duodenal ulcer (7 cases), chronic and recurrent pancreatitis (7 cases), hiatus hernia (2 cases), and 10 miscellaneous ailments. In this entire group the common bile ducts of 4 patients failed to be visualized, in 11 they were dilated, and in 11 they were of normal diameter. Our results were inconclusive as regards pancreatitis—the common bile ducts were of normal diameter in three patients, dilated in two, and invisible in two. In none of the patients with pancreatitis did we observe any characteristic tapering, constriction, or displacement of the lower end of the common bile duct.

TABLE 1.—*Summary of Findings in 121 Patients* with Postcholecystectomy Syndrome*

		Patients			
		No.		%	
Common bile ducts visualized		105		86.8	
Known extrahepatic disease			26		21.5
Duodenal ulcer	7				
Pancreatitis	7				
Hiatus hernia	2				
Miscellaneous	10				
Known parenchymal disease			10		8.3
Cirrhosis	5				
Hepatitis	2				
Polycystic disease	1				
Tumor	1				
Type undetermined	1				
Major duct abnormalities			40		33.0
Cystic duct remnants	20				
Strictures and adhesions	9				
Stones	11				
Dilatation only			29		24.0
No duct visualization (normal liver)		1		0.8	
No abnormality		15		12.4	
Total		121		100	

* 100 women, 21 men.

Disease of the Liver Parenchyma.—Ten individuals (8.3%) presented clinical and laboratory evidence of liver damage. These, as summarized in table 1, included five cases of cirrhosis, two of hepatitis, and one each of tumor, polycystic disease, and unknown hepatocellular disease. In only 3 of these 10 patients could the common bile duct be identified.

Lesions of the Major Bile Ducts.—Mechanical defects capable of irritating or obstructing the bile ducts were demonstrated in 40 patients (33%) and are listed in table 1. The most common lesion was a persistent cystic duct stump (fig. 1), which was shown in 20 individuals (16.5%). This is a significant figure if one accepts the evidence of Beye,[6] Gray and Sharpe,[7] and Garlock and Hurwitt[8] that these remnants cause symptoms by virtue of chronic inflammation and calculus formation induced in a blind sac. In four individuals the stumps contained calculi, and in one the stump contracted as a gallbladder might do after a fat meal. The cystic duct remnant often followed an unusual course, lying parallel with the common bile duct or crossing it to insert on its medial wall. In nine patients (7.4%) we demonstrated marked angulation, distortion, or stricture of the common bile duct (fig. 2).

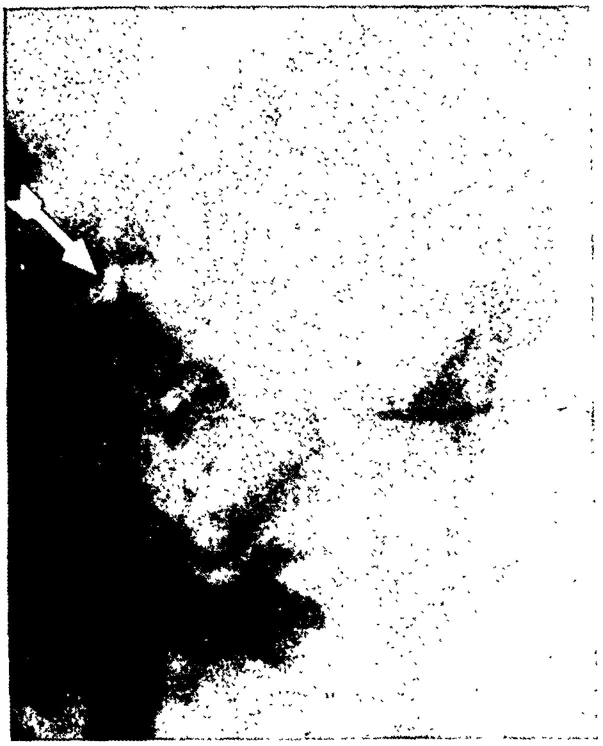

Fig. 1.—Roentgenogram made 30 minutes after injection of sodium iodipamide. A cholecystectomy had been performed 15 years previously, but the patient continued to complain of intermittent epigastric pain and vomiting. Note the long cystic duct remnant (arrow) lying close to the common bile duct. The valves of Heister are clearly visible.

In a total of 11 patients (9.1%) calculi were lodged in the extrahepatic ducts. Ten of these calculi could be seen on the cholangiograms (fig. 3); one could not be seen because of inadequate duct opacification. In seven instances the stones were in the common bile duct; in the four cases previously cited they were lying in the cystic duct stump. Eight patients with choledocholithiasis were not jaundiced; in two there was borderline elevation of the serum bilirubin level and in one faint scleral icterus at the time of examination. Seven of these 11 patients have been operated on and their stones removed; 4 have not yet been explored. We have found body-section roentgenography an indispensable adjunct to conventional projections, and we use it almost routinely.

Dilatation of the Common Bile Duct.—Dimensions of the common bile duct vary considerably when measured roentgenographically. This is not unusual if one recalls that the ducts have been measured when distended under pressure during operative cholangiography[9] or during oral cholangiography when their diameters were modified by a functioning, distensible gallbladder.[3b] We have arbitrarily set 7 mm. as the upper limit of normal common bile duct diameter, measuring it on a posteroanterior projection, employing a 40 in. target-film distance. We refer to any duct larger than 7 mm. in maximum diameter as dilated.

Marked dilatation was noted in 9 of the 10 common bile ducts in which stones were demonstrated, the average diameter in this group being 15 mm. and the maximum diameter 25 mm. (table 2). There was less dilatation associated with persistent cystic duct stump, stricture, and adhesion—the average diameter in this category being 9 mm. In 29 individuals (24%), a group presumably including patients with fibrosis or reflex spasm of the sphincter of Oddi, the only recorded abnormality was dilatation of the common bile duct (table 2). We could detect no constant relationship between the size of the common bile duct and the time that had elapsed since cholecystectomy.

It should be possible, in theory at least, to deduce the degree of bile stasis resulting from spasm or fibrosis of the choledochal sphincter by determining how soon after injection sodium iodipamide appears in the duodenum. This is a tantalizing figure. It is also unreliable for a number of reasons, chief of which is the languid sense

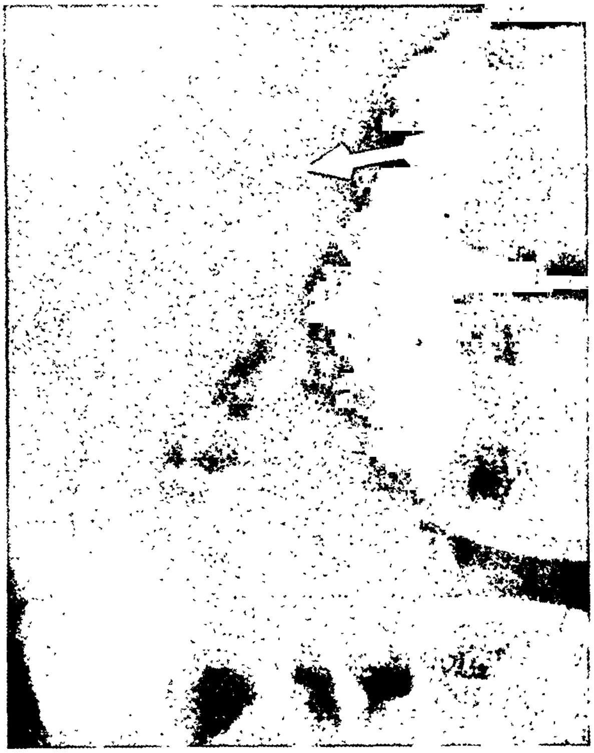

Fig. 2.—Common bile duct stricture. Roentgenogram demonstrating a slightly dilated common hepatic duct and an abrupt stenosis of the common bile duct (arrow) at the point where the cystic duct would normally enter it. The patient was a 36-year-old housewife, troubled by episodes of right upper quadrant pain, fever, and jaundice since cholecystectomy 10 years before.

of time of the average technician when it comes to taking and marking films at precise intervals. An added difficulty is that of positively identifying a contrast agent in a duodenum partially obscured by the colon, the kidney, and the common bile duct itself.

Normal Common Bile Ducts.—In 15 patients with postcholecystectomy symptoms the common bile duct was of normal diameter and in every other way roentgenographically normal. In one obese individual without any evidence of hepatic insufficiency we were unable to demonstrate any common bile duct at all, probably for technical reasons.

CONTROL SERIES OF ASYMPTOMATIC PATIENTS

Forty-six patients (42 women and 4 men) from the follow-up surgical clinic who reported themselves free of any digestive symptoms after cholecystectomy agreed to have intravenous cholangiograms taken. The common bile ducts of 44 of these 46 were outlined (95.6%). Every type of duct lesion, including stones, that had been observed in patients with the postcholecystectomy syndrome was demonstrated in the control series (table 3). In terms of percentage, the incidence of duct disorders was almost identical in both series, and, though they were often small, cystic duct remnants were seen almost twice as frequently in the control group—28.3% as against 16.5%. Stones in the common bile duct were demonstrated in two asymptomatic patients. In one, a solitary stone was lodged at the junction of the right and left hepatic duct; in the other (fig. 4), the common bile duct was filled with faceted stones.

TABLE 2.—*Dimensions of Major Bile Ducts*

	Patients with Symptoms	Asymptomatic Control Patients
No. of Patients	121	46
Ducts Visualized	105 (87.0%)	44 (95.6%)
Mean common duct diameter	9 mm.	9 mm.
Ducts less than 8 mm. in diameter	38 (31.5%)	17 (36.9%)
Ducts more than 8 mm. in diameter	67 (55.5%)	27 (58.7%)
Dilatation the only abnormality	29 (24.0%)	19 (40.4%)
Calculus	11	2
Mean common duct diameter	15 mm.	14 mm.
Cystic duct stump	20	13
Mean common duct diameter	9 mm.	8 mm.
Stricture and adhesion	9	1
Mean common duct diameter	9 mm.	13 mm.

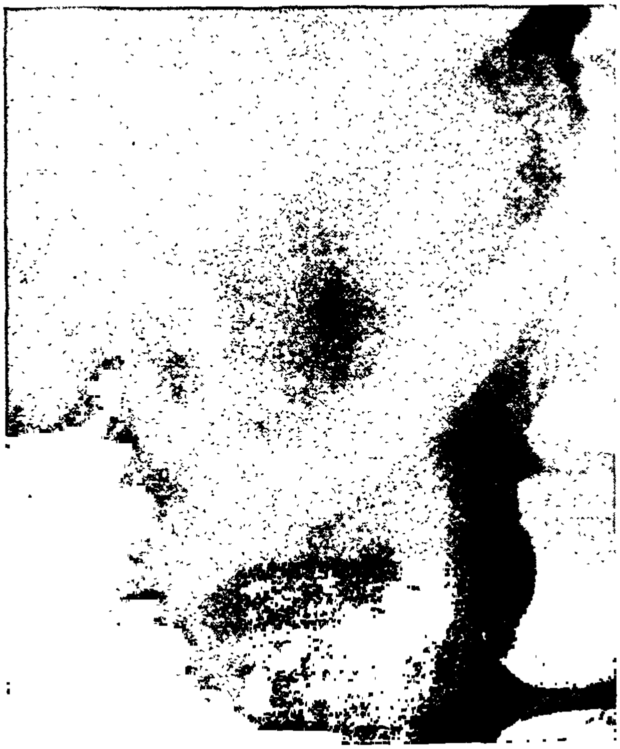

Fig. 3.—Roentgenogram, 20 minutes after injection of sodium iodipamide, showing a single triangular stone lodged in a dilated common bile duct. The patient was a 53-year-old housewife admitted to the hospital with clinical and electrocardiographic signs of coronary occlusion. Eight days later she began to vomit and complain of abdominal pain, and an intravenous cholangiogram was requested. The calculus was surgically removed, and she has since been well except for chronic coronary heart disease.

In both groups of patients the mean diameter of the common bile duct was the same—9 mm. (table 2). In both series stones in the common bile duct produced the most dilatation, and, in approximately 60% of symptom-free patients, the common bile duct was 8 mm. or more in diameter (fig. 5). There was a slight difference in the time required for the contrast agent to reach the duodenum (table 4). In 72% of the patients with postcholecystectomy symptoms sodium iodipamide could be identified in the duodenum within 30 minutes or less. In the control series this figure was 53%. The limitations of these statistics have already been described, but they do not suggest that any conspicuous stasis of bile occurs in the recurrent biliary tract syndrome.

TABLE 3.—*Comparison of Lesions of Major Bile Ducts in Patients with Symptoms and Asymptomatic Control Patients*

Strictures and adhesions	9	7.4	1	2.2
Calculi	11	9.1	2	4.3

COMMENT

The "silent" gallstone has been the subject of lively debate among clinicians.[10] Our results indicate that a stone may lie as silently in the common bile duct as in the gallbladder, a fact often presumed to be true.[11] The persistent cystic duct stump, always incriminated when found to be inflamed at operation, may also remain silent. In fact it often appears to do so.

---

[10] Robertson, H. E.: Silent Gallstones, Gastroenterology 5:345 (Nov.) 1945.

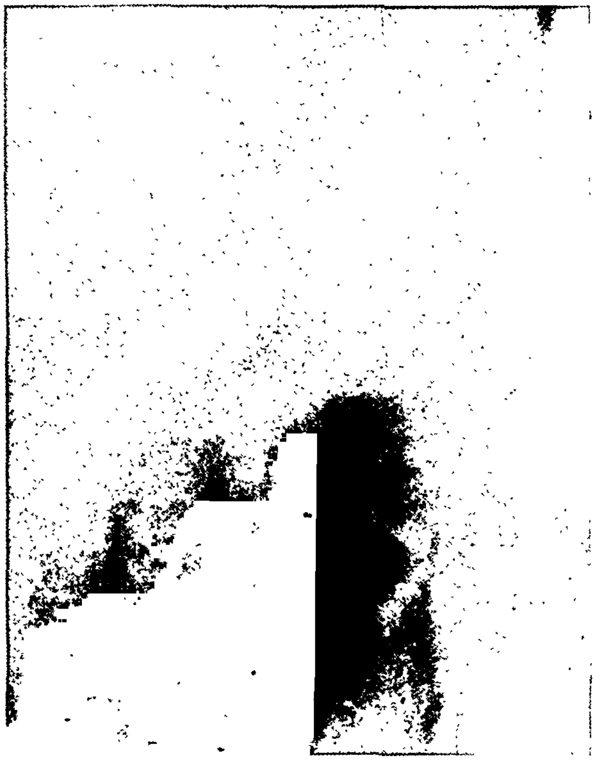

Fig. 4.—Tomogram showing silent stones in the common duct. The patient, a 40-year-old woman, had a cholecystectomy in 1952. She has since had no digestive complaints but was asked to have an intravenous cholangiogram as a postcholecystectomy control. Note the slightly dilated common bile duct, filled with faceted stones, and the wide, pendulous cystic duct stump.

In his experiments with dogs Oddi[12] observed that the common bile ducts of some mammals dilate after cholecystectomy. In 1926 Counseller and McIndoe,[13] using a celloidin-corrosion technique, reconstructed the biliary trees of 26 human subjects at autopsy. They found that when the liver and gallbladder were normal the diameter of the common bile duct did not exceed 5 mm. but that there was constant dilatation of the common bile duct immediately after cholecystectomy in subjects whose gallbladders contained unsuspected stones. They found liver atrophy and diffuse duct dilatation (hydrohepatosis) associated with choledochal obstruction of even a moderate degree. The intravenous cholangiograms we have described showed almost constant common bile duct dilatation after cholecystectomy, both in patients with and without symptoms. Whatever may be the mechanics involved—anatomic, hydraulic, or neurological—it seems likely that dilatation of the human common bile duct usually results when disease or surgical resection deprives it of a concentrating and distensible reservoir in the gallbladder.

TABLE 4.—*Time Required for Contrast Agent to Reach Duodenum*

	Patients with Symptoms		Asymptomatic Control Patients	
	No.	%	No.	%
No. of biliary ducts demonstrated	105	....	44	....
In duodenum				
15 min. or less	33	31.0	10	23.0
16-30 min	43	41.0	13	29.5
31-60 min	22	21.0	13	29.5
Not in duodenum in more than 60 min	5	5.0	5	11.0
Examination prematurely discontinued	2	2.0	3	7.0

We have shed little light on the problem of biliary dyskinesia and cannot offer any evidence of increased bile stasis in the common duct when patients with symptoms are compared with symptom-free controls. It may be that detailed measurements of the common bile duct and sphincter of Oddi would have shown a different reaction to antispasmodic drugs in the two groups.

SUMMARY

A series of intravenous cholangiograms of 121 patients, with pain and indigestion persisting after cholecystectomy, has been compared with a control series of 46 patients who were free of symptoms after the same operation. Common bile duct abnormalities were demonstrated in 33% of the patients with symptoms. These included cystic duct remnants (16.5%), calculi (9.1%). and adhesive bands and strictures (7.4%). Disorders of the common bile duct were demonstrated in 16 members of the control series (34.8%). These included cystic duct remnants (28.3%), calculi (4.3%), and adhesive bands and strictures (2.2%).

In both series the mean common bile duct diameter was 9 mm. and the greatest amount of common bile duct dilatation was caused by calculi. No significant bile stasis was shown in patients with postcholecystectomy symptoms; in these sodium iodipamide (Cholografin) appeared to reach the duodenum slightly earlier than in patients of the control group. Intravenous cholangiography is an efficient method of demonstrating possible causes of recurrent symptoms after cholecystectomy, but reasonable doubt may exist that the procedure has shown the actual cause of the patient's complaints. It is no substitute for sound clinical judgment.

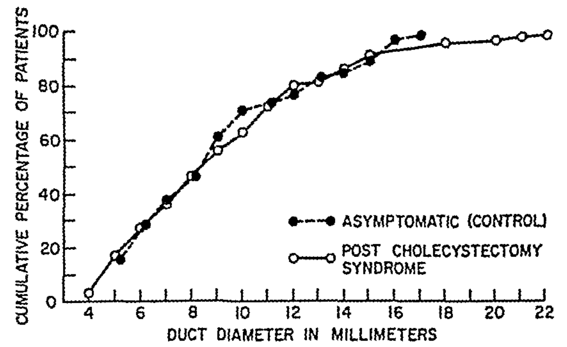

Fig. 5.—Chart of cumulative percentages showing the frequency with which ducts of specific size were demonstrated in symptomatic and control patients.

ORAL CHOLECYSTOGRAPHY WITH IOPANOIC ACID (TELEPAQUE)

Lawrence Reynolds, M.D.
and
Harold Fulton, M.D., Detroit

Since the introduction of iopanoic acid (Telepaque) in 1951, extensive clinical application has demonstrated that this medium represents an ideal cholecystographic agent.[1] Iopanoic acid [β-(3-amino-2, 4, 6-triiodophenyl)-α-ethylpropionic acid] contains 66.68% iodine. This triiodide is readily absorbed by the small intestine and is excreted in the bile within two hours after oral administration. Maximum concentration in the gallbladder occurs at from 10 to 12 hours. Iopanoic acid is excreted mainly through the intestinal tract; elimination is rapid and complete within 48 hours. Toxic reactions to the medium are rare, and side-effects are minimal. In addition to providing visualization of the gallbladder, in a significant percentage of examinations the bile ducts, particularly the cystic and common ducts, are outlined.[2]

The accuracy of cholecystography in detecting the presence of gallbladder disease and cholelithiasis has been estimated at 99%.[3] This high degree of diagnostic reliability has made cholecystography one of the most accurate of roentgen tests. To fully exploit the diagnostic potentiality of a cholecystographic medium such as iopanoic acid, certain details of technique must be followed. To illustrate various features of cholecystography with iopanoic acid, the results in our series of 1,000 consecutive cholecystographic examinations are interspersed with our discussion.

DOSAGE

The manufacturers of iopanoic acid recommend a dose of 3 gm. for the average patient and 2 gm. for those patients "of thin or normal build, weighing less than 150 pounds. . . . If visualization of extrahepatic ducts is especially indicated, from five to six grams are recommended." Of the 910 (91%) patients in our series with visualized gallbladders, the orally given dose of iopanoic acid varied from 2 to 8 gm., depending on the patient's body weight. The mean dose was 3.47 gm. The cholecystographic density in each instance was tabulated as poor, fair, good, or excellent (table 1). The relative distribution of the degree of cholecystographic density in this series of patients is in accord with published observations.[1]

With the dosage of iopanoic acid even as high as 8 gm , no severe reactions occurred, and the unabsorbed contrast medium in the intestine never seriously interfered with cholecystography. In fact, the presence of iopanoic acid in the large intestine is positive evidence that the medium was ingested and had traversed the small intestine. It is questionable, however, if doses of iopanoic acid exceeding 3 gm. are necessary for accurate cholecystography. Many authors, particularly Christensen and Sosman [1a] and Whitehouse,[3b] believe that 2 gm. is sufficient for cholecystography in the average patient. Two personal observations support this idea. First, in 90 cases of nonvisualized gallbladders in the series of 1,000 examinations, a repeat cholecystography was done, usually employing a double dose of the contrast medium. In only four instances (4.4%) was the gallbladder visualized with the larger amount of iopanoic acid. In all of these four cases cholecystographic density on the second examination was poor. Therefore, in over 95% of those patients with nonvisualized gallbladders the smaller dose of iopanoic acid was adequate, and in 100% it allowed accurate prediction of severe gallbladder disease. Second, repeat study was done with smaller doses (1 or 2 gm.) in several patients in whom cholecystography with 2 or 3 gm. of iopanoic acid yielded excellent cholecystographic density. In all instances, excellent or good cholecystographic density resulted (fig. 1).

Although bile duct demonstration in oral cholecystography is directly dependent upon the degree of gallbladder opacification (table 2), it appears to be relatively independent of the orally given dose (table 3). The advisability of routinely employing doses of iopanoic acid greater than 3 gm. to enhance bile duct visualization is doubtful.

TECHNIQUE

The routine technique employed with the earlier orally given cholecystographic mediums has been applied to cholecystography with iopanoic acid. Although clinical results have proved satisfactory, it is noteworthy that, while the maximum concentration of iopanoic acid in the gallbladder occurs 10 to 12 hours after oral administration, sufficient medium for diagnostic purposes may be present [1c] 4 to 6 hours after oral administration. This fact can have useful clinical application, particularly in these days of rapid roentgenologic surveys.

Postcibum roentgenograms exposed after the standard fat meal or special liquid meal [1d] (an 8 oz. glass of eggnog containing the yolks of two eggs and 2 oz. of cream) are of particular significance in cholecystography with iopanoic acid. Bile ducts (cystic duct, common bile

duct, and common hepatic ducts) are opacified in a percentage of cholecystograms ranging from 50 [1d] to 91%.[2a] In our series the bile ducts were satisfactorily outlined in 58% of the cases in which the gallbladder was visualized. In these instances a single exposure was made approximately 20 minutes after ingestion of a standard fat meal. If additional postcibum roentgenograms had been exposed at 5 to 10 minute intervals in serial fashion, the percentage of bile duct visualization would undoubtedly have been increased. In none of the 534 patients in whom the bile ducts were demonstrated was there evidence of common duct stone or stenosis. In three cases in which the gallbladder was not visualized, a dilated common duct was shown, and in one of these ducts a solitary radiolucent calculus was delineated.

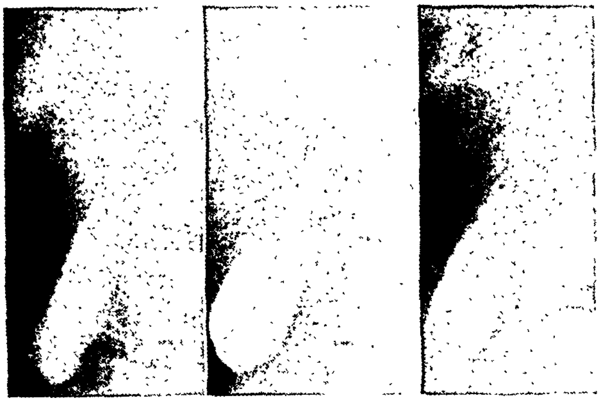

Fig. 1.—Cholecystograms of a 126 lb. (57.2 kg.) individual taken at monthly intervals, employing 3, 2, and 1 gm. of iopanoic acid respectively. Cholecystographic density is the same with each oral dose.

Table 1.—*Cholecystographic Density in 910 Patients*

	No.	%
Poor	68	7.5
Fair	208	22.8
Good	382	42.0
Excellent	252	27.7

Shehadi [2b] has stated, "In the present state of our knowledge we are justified in considering visualization of the hepatic duct as evidence of obstruction at a point distal to the hepatic duct. This may be temporary when spasm of the sphincter of Oddi occurs and the caliber of the hepatic duct remains normal." Visualization of the common hepatic duct, usually its distal 1 to 2 cm., was accomplished in 42% of our patients in whom the common bile duct was also visualized. In none of these cases was the diameter of the common bile duct greater than 7 mm.; at least one-half of the ducts were 3 mm. or less in diameter. It therefore appears that hepatic duct visualization is to be expected in a significant percentage of patients without evidence of organic obstruction of the common bile duct.

Table 2.—*Relation of Bile Duct Visualization to Cholecystographic Density*

Poor	12
Fair	45
Good	63
Excellent	77

That exhibition of certain drugs such as morphine and neostigmine (Prostigmin) will enhance bile duct visualization during cholecystography by the mechanism of increase in sphincter (Oddi's) tone is well known. This method of producing bile duct opacification during oral cholecystography with iodoalphionic acid (Priodax)[2c] has been employed, but it is probably an unnecessary maneuver in cholecystography with iopanoic acid.

ROENTGENOLOGIC FACTORS

Cholecystography demands exacting roentgenologic technique. With modern roentgenographic equipment, exposures can be made at 0.1 to 0.3 second, at 200 to 400 ma., and with 70 to 80 kv. This kilovoltage range is important in the preservation of proper contrast between the opacified gallbladder and calculi or polyps. High kilovoltage studies (90-115 kv.) have, in our experience, proved inferior to the lower kilovoltage method, insofar as calculus detection is concerned. Routine roentgenograms (posteroanterior prone and oblique prone or supine) should be supplemented either by an upright or lateral decubitus exposure, the latter to detect small floating calculi or fundic sand. An initial

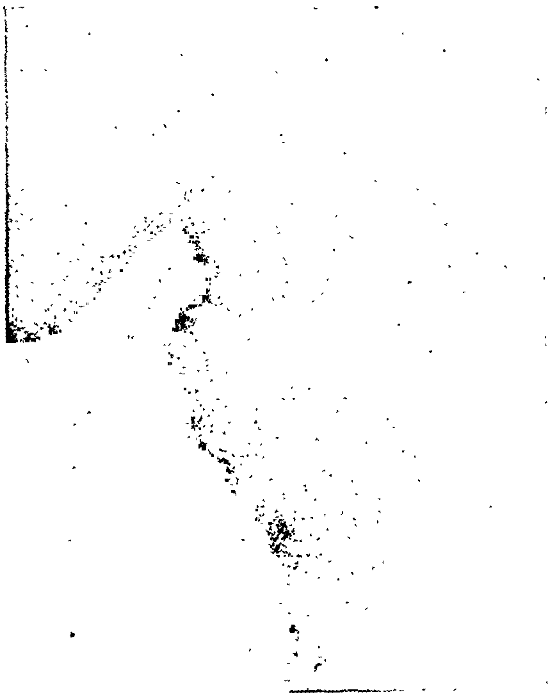

Fig. 2.—Routine cholecystogram showing excellent cholecystographic density, with no calculus visible.

exposure should be made on film of sufficient size to detect gallbladders of unusual or abnormal position; other exposures should be carefully "coned down" to insure maximum detail. It has been suggested that the high degree of opacification of the gallbladder frequently encountered in cholecystography with iopanoic acid may actually preclude on occasions roentgenographic demonstration of small calculi. Two techniques may obviate this possible source of cholecystographic error—spot-filming and body section roentgenography.

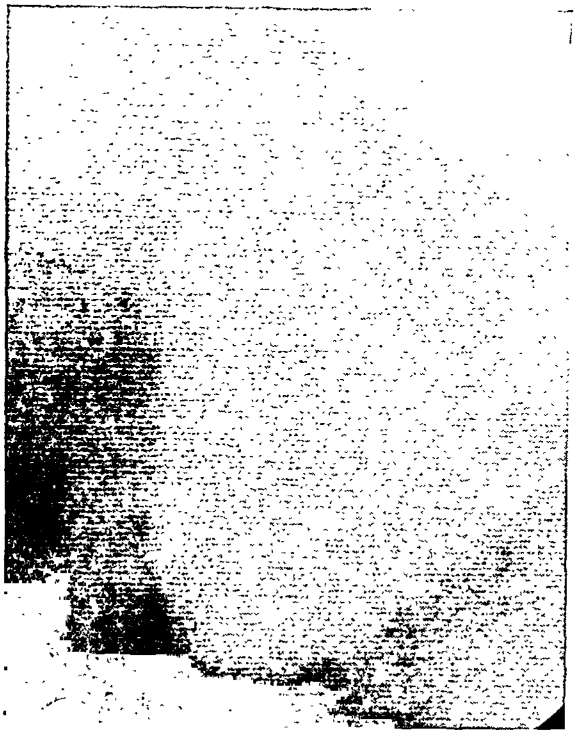

Fig. 3.—Spot pressure roentgenogram demonstrating multiple small opaque calculi.

The density of the filled gallbladder obtained in cholecystography with iopanoic acid allows satisfactory visualization by fluoroscopy. The gallbladder can thus be palpated, displaced, and, more important, compressed under roentgenoscopic guidance, and film records can be made by the spot-film technique. Lubert and Krause [4] describe this technique in detail and mention a clear space just lateral to the lumbar spine, overlying the apex of the right psoas muscle, where both the colon and descending duodenum are usually avoided and the pressure on the gallbladder is most effective. Spot-filming of the gallbladder in preference to roentgenograms with the patient in the upright or decubitus position (Bucky film) is used by these authors routinely, except where stones are obvious on the routine roentgenograms. In our experience, spot-filming is practical only in those patients in whom gallbladder density is good or excellent, but in an occasional patient it may prove essential for proper diagnosis (fig. 2 and 3). Mobility of the gallbladder and flexibility of its wall, as determined by palpation under fluoroscopy, have no practical importance, and attempts at manual expression of contrast medium from the gallbladder, with subsequent filling of the bile ducts, have proved unsuccessful.

Another method for visualization of obscured calculi is body section roentgenography.[5] This is a time-consuming technique that requires special equipment and that is applicable in those rare cases in which overlying intestinal shadows prevent satisfactory demonstration of the gallbladder by the usual roentgen methods (fig. 4). Fluoroscopy and spot-filming in general are to be preferred to body section roentgenography.

Demonstration of the extrahepatic bile ducts during oral cholecystography requires precise roentgenographic technique. Although this particular phase of cholecystography may be accomplished with the patient in a prone position, the supine position, with the patient's left side elevated 10 to 15 degrees from the table top, seems to be the most advantageous. If the examination is performed on a tilt table, use of the Trendelenburg position (patient's head 20 to 25 degrees below the horizontal plane) will serve to augment bile duct opacification.

COMMENT

One thousand consecutive cholecystograms in which iopanoic acid was used, performed within a period of 11 months at Harper Hospital, were reviewed and critically analyzed. In 91% the gallbladder was visualized; in 9% no visualization of the gallbladder resulted. Calculi were demonstrated in 15% of the visualized gallbladders and in 18% of the patients without gallbladder opacification. In addition, there were two examples of limy bile, in one of which cholesterol-type calculi were delineated by the liquid calcium carbonate within the

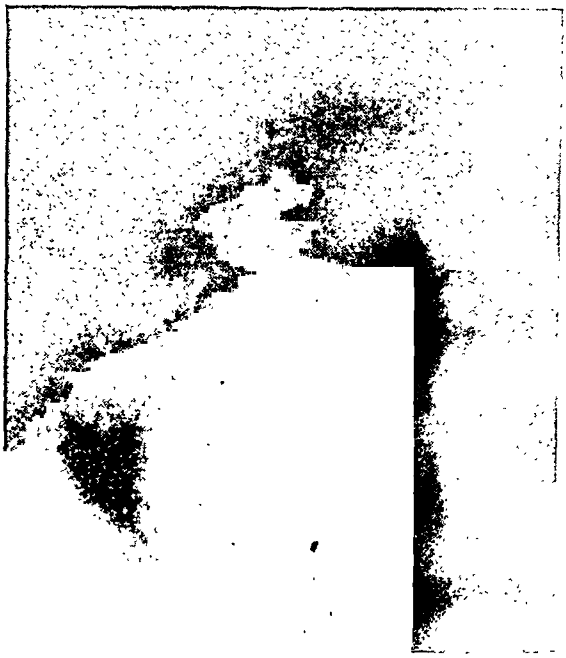

Fig. 4.—Laminagraphic demonstration of solitary cholesterol-type calculus, obscured by overlying intestinal gas on routine cholecystograms.

gallbladder lumen. In three patients with excellent opacification of the gallbladder a papilloma was demonstrated roentgenographically. Thus, in 33.3% of the patients studied, significant gallbladder disease was discovered cholecystographically with iopanoic acid.

Bile ducts (cystic and common ducts) were outlined satisfactorily in 58% of the total cases. In none of the patients with visualized gallbladders was the common duct abnormal. In three patients whose gallbladders could not be visualized, a dilated common duct was shown, and in one of these latter patients a nonopaque calculus was present in the common duct. The common hepatic duct, usually its distal 1 to 2 cm., was outlined in 42% of the patients in whom the common bile duct was visualized.

CONCLUSIONS

Iopanoic acid (Telepaque) is in our opinion almost an ideal cholecystographic agent. With iopanoic acid the accuracy of oral cholecystography in detecting the presence of gallbladder disease and cholelithiasis approaches 100%. In addition, the cystic, common, and hepatic bile ducts can be visualized in from 50 to 100% of patients with functioning gallbladders. Certain details in the use of this contrast medium and the cholecystographic and roentgenographic techniques employed are significant in attaining the high degree of diagnostic reliability inherent in this medium. Results in a series of 1,000 consecutive cases illustrate selective features of cholecystography with iopanoic acid.

EXPERIENCE WITH FIVE ORALLY GIVEN CHOLECYSTOGRAPHIC MEDIUMS

Everett E. Seedorf, M.D.
and
William N. Powell, M.D., Temple, Texas

The history of cholecystography has been reviewed in the literature.[1] Iodophthalein sodium (Iodeikon), producing a high degree of cholecystographic accuracy, was the first orally given cholecystographic medium to be popularized. In fact, it is doubtful whether the administration of subsequent orally given mediums actually has increased the accuracy of diagnosis for cholecystic disease. The chief objections to iodophthalein sodium were its disagreeable taste and the high incidence of nausea, vomiting, and diarrhea following oral administration. Iodoalphionic acid (Priodax) was tolerated much better and almost universally replaced iodophthalein sodium. Monophen, 2-(4-hydroxy-3,5-diiodobenzyl)-cyclohexane carboxylic acid, although well tolerated and capable of producing equally good cholecystograms, never became popular and is no longer manufactured. Although iodoalphionic acid is employed occasionally, iopanoic acid (Telepaque) and iophenoxic acid (Teridax) are the cholecystographic mediums used most frequently today.

It is generally agreed that an ideal orally given cholecystographic medium should produce a gallbladder shadow of sufficient density to clearly outline the organ, yet permit sufficient penetration by the x-ray beam to show filling defects produced by opaque and nonopaque stones. Also, it is desirable, but not always possible, to simultaneously outline the cystic duct. The medium should be well tolerated and produce few reactions. It should be completely absorbed and leave no opaque residue in the intestine. In our paper, the following five orally given cholecystographic mediums will be discussed: iodophthalein sodium, iodoalphionic acid, Monophen, iopanoic acid, and iophenoxic acid.

CLINICAL INVESTIGATION

Each of the five mediums were investigated and then compared for (1) quality of the cholecystograms produced, (2) side-effects encountered, and (3) production of pseudoalbuminuria. With the exception of iodophthalein sodium, the action of each drug was observed in 100 patients after administration. (At the time of our investigation iodophthalein sodium was no longer being manufactured so that our studies with this medium were limited by a small donated reserve.) In the attempt to produce cholecystograms of optimal density, with the gallbladder shadow distinctly visible but not obscuring stones, we concluded that the following dosages most completely and consistently met our needs: iodophthalein sodium, 4 gm.; iodoalphionic acid, 3 gm.; Monophen, 3 gm.; iopanoic acid, 2 gm.; and iophenoxic acid, 3.8 gm.

A relatively small dosage of iopanoic acid (2 gm.) produces a gallbladder shadow of optimal quality. With larger doses, it is frequently possible to visualize the cystic duct, occasionally demonstrating stones or other abnormalities. Sehested[2] has demonstrated that after a fat meal the gallbladder may express its contents on an average of every two minutes. Since the cystic duct is visualized only while the gallbladder is expressing its contents, it is by chance that a cholecystogram is made at the proper moment for visualization of the duct, the chance being best when the exposure is made 15 to 20 minutes after the fat meal. Accordingly, reports of visualization of the cystic duct vary from 10 to over 50%.

From the Department of Radiology (Dr. Seedorf) and the Department of Clinical Pathology (Dr. Powell), Scott and White Clinic. Dr. Seedorf is now affiliated with the Hanna Clinic, Peoria, Ill.

Read in the Symposium on Newer Contrast Media for Visualization of the Biliary Passages, before the Section on Radiology at the 104th *Annual Meeting of the American Medical Association, Atlantic City, June* 9, 1955.

Iodophthalein sodium was contributed by the Sisters of St. Francis Hospital, La Crosse, Wis. Monophen was furnished for this study by Bell-Craig, Inc., New York; iopanoic acid (Telepaque) by Winthrop-Stearns, Inc., New York; and iophenoxic acid (Teridax) by Schering Corporation, Bloomfield, N. J.

[2] Sehested, H. C.: Study of the Gallbladder and the Common Duct by Oral Dye, Texas J. Med., to be published.

Iodoalphionic acid, iopanoic acid, and iophenoxic acid, in varying dosages, are of apparently equal value for establishing a correct cholecystographic diagnosis. In our institution, we have attempted to produce a gallbladder shadow of slightly greater density than that previously produced with 3 gm. (6 tablets) of iodoalphionic acid. This was achieved with 2 gm. (4 tablets) of iopanoic acid. Our objection to this medium is that it frequently became difficult to differentiate between the opaque residue of iopanoic acid seen in the intestine and the calcification within the abdomen. We now employ iophenoxic acid and have found, as no doubt would be true with other cholecystographic mediums, that prescribing the dosage of iophenoxic acid on the basis of body weight produces a greater uniformity in the gallbladder density. We have definitely reduced the number of reexaminations among heavier individuals. The recommended dosage of iophenoxic acid, according to weight of the patient, can be found in table 1.

TABLE 1.—*Dosage of Iophenoxic Acid as Determined by Weight of Patient*

Iophenoxic Acid Tablets	Weight, Lb.
4 (3.0 gm.)	Under 125
5 (3.8 gm.)	125 to 175
6 (4.5 gm.)	175 to 200
7 (5.3 gm.)	Over 200

COMMENT

Although we have no statistics to support our assumption, our experience indicates that the number of reexaminations necessary, due to obscuring gas, has been considerably less with iophenoxic acid than with iodoalphionic acid. Early in 1954, an allotment of iophenoxic acid, causing opaque residue in the intestine due to incomplete dissolution of the tablets, was distributed through trade channels; these were taken off the market and replaced by more refined ones. No opaque residue caused by the medium has been reported with the use of the improved tablets.

A report of untoward reactions from use of iodophthalein sodium (table 2) encountered in 600 patients was published in 1934 by Newell and Leef.[3] This report compares closely with reactions subsequently reported by other authors for smaller series of patients. The disagreeable taste of the drug frequently produced nausea, and diarrhea was a common complaint. Unfug[4] observed that the drug caused a 4% incidence of dysuria. Cholecystographic drugs introduced since, and including, iodoalphionic acid produce less frequent and severe diarrhea. Dysuria of short duration occurs most often, since the medium is primarily excreted by the kidneys. Table 2 shows all the drugs produce untoward reactions of about the same frequency and intensity; however, they are usually of short duration and are not severe enough to contraindicate use of a specific medium.

TABLE 2.—*Side-Reactions with Cholecystographic Mediums*

	Mediums				
Side-Reactions	Iodophthalein Sodium, %	Iodoalphionic Acid, %	Monophen, %	Iopanoic Acid, %	Iophenoxic Acid, %

* Reported by Unfug.[4]
† As recorded by Newell and Leef.[3]

Previous publications[5] have recorded an incidence of pseudoalbuminuria, from 14 to 17%, occurring the day after ingestion of the orally given cholecystographic mediums iodoalphionic acid, Monophen, iopanoic acid, and iophenoxic acid. With all mediums, a false-positive test for albumin in the urine persisted for two to three days in a few patients. It is significant that, if the hot Exton's reagent is allowed to cool before interpretation, chance of error in reporting albuminuria is greatly increased (table 3). As report of albumin in urine can mar a patient's health record for further insurance consideration, pseudoalbuminuria is significant.

TABLE 3.—*Incidence of Pseudoalbuminuria*

		Pseudoalbuminuria, %	
Cholecystographic Mediums	Gm.	Exton's Reagent, Hot	Exton's Reagent, Cold
Iodophthalein sodium (8 patients)	4.0	0	50
Iodoalphionic acid	3.0	14	60
Monophen	3.0	17	65
Iopanoic acid	2.0	15	43
Iophenoxic acid	3.8	14	63

SUMMARY

Iodoalphionic acid (Priodax), iopanoic acid (Telepaque), and iophenoxic acid (Teridax) are the cholecystographic mediums used almost exclusively in the United States. Although they differ in chemical structure, they are tolerated quite similarly. Cholecystograms are of about the same diagnostic value, and, by adjustment of the dosage, gallbladder shadows of similar density can be obtained with all three mediums. Few reactions are produced, but, although it is reported infrequently, the occurrence of pseudoalbuminuria is significant. Iopanoic acid apparently is capable of producing the gallbladder shadow of greatest density and probably excels in demonstration of the extrahepatic ducts. It has the disadvantage, however, of producing an opaque residue in the intestine, which may be confused with shadows from calcification within the abdomen. Iophenoxic acid, with its dosage regulated according to the weight of the patient, is now used exclusively in our institution. It produces a sharply outlined, homogeneous gallbladder shadow and leaves no confusing residue.

CLINICAL NOTES

PRODUCTION OF PREMATURE VENTRICULAR CONTRACTIONS BY RAUWOLFIA

Ben N. Wilson, M.D.
and
Norris A. Wimberley Jr., M.D., Tyler, Texas

Alkaloids of Rauwolfia serpentina (Ophioxylon serpentinum) are currently enjoying great popularity for treatment of a wide variety of disorders, ranging from insanity to various forms of hypertension. While this drug has been in use for many years in India, a large pharmacological literature is not available.[1] Allen and co-workers,[2] in discussing its use in hypertension, state that it "inhibits sympathetic system and reduces blood pressure by direct action on hypothalamus. Apparent parasympathomimetic action. Produces tranquility without somnolence." Toxic symptoms are said to include nasal congestion and stuffiness, mild bradycardia, sedation, muscular aching and stiffness, laxation, and at times nightmares and mental depression.[3] Paresthesias, twitching of the limbs, chattering of the teeth,[4] and pruritus [5] have also been reported. We wish to report an additional and possibly significant toxic effect—ventricular premature contractions.

We have been unable to find any report suggesting cardiotoxic effects. In August, 1953, one of us (B. N. W.) first noted the occurrence of ventricular premature contractions in a patient receiving the powdered whole root of Rauwolfia serpentina, Raudixin, for the control of hypertension (case 1). Since that time, careful observation of patients receiving this medicament has revealed three additional cases. In three instances, there has been moderate to severe associated symptomatology necessitating withdrawal of the drug, and, in two instances, reinstitution of the drug has caused recurrence of the symptomatology and ventricular premature contractions.

REPORT OF CASES

CASE 1.—A 46-year-old female, known to have had severe hypertension of 20 years' duration, sustained an acute myocardial infarction in 1946 and in 1948. She developed mild congestive failure in 1950, requiring treatment with digitalis and diuretics, which has been continued since that time. There was progressive evidence of peripheral arteriosclerosis with gangrenous lesions of the toe of the right foot and, in 1953, a gangrenous lesion on the left middle finger. In July, 1953, the patient's blood pressure was 240/130 mm. Hg, and she was started on Raudixin therapy, 100 mg. twice daily. Two weeks later she was forced to discontinue taking Raudixin because of irregularity of the pulse. A doctor did not examine her at this time. She stopped taking Raudixin for one week, after which time she felt that her pulse was regular. On resuming treatment with the medicine, she noted that within two days' time the pulse tended to be irregular again, and on examination at this time she was found to have a rhythm of frequent ventricular premature contractions, at times amounting to a bigeminal rhythm. Raudixin therapy was discontinued, and subsequent examinations have not shown a return of the premature ventricular contractions.

CASE 2.—On Aug. 19, 1954, the blood pressure of a 42-year-old female was 210/120 mm. Hg when she consulted another physician for menorrhagia. On Aug. 25, 1954, treatment with Raudixin, 100 mg. twice a day, was begun. On Sept. 7, 1954, the patient's blood pressure was still 220/120 mm. Hg. The examination of the heart showed a bigeminal rhythm due to premature ventricular contractions, and she complained of considerable weakness. Raudixin therapy was discontinued, and three days later the pulse was regular with no premature ventricular contractions. Treatment with Raudixin was resumed at a lower dosage level, with only 100 mg. daily being administered, but was discontinued two weeks later because the patient felt that it made her weak. She had not, however, noted any return of the premature ventricular contractions on the smaller dosage schedule.

CASE 3.—A 60-year-old female complaining of high blood pressure and heart trouble was seen in February, 1949. Medical history revealed diphtheria at the age of 8 years and pneumonia during the influenza pandemic in 1918. Appendectomy had been performed in 1945, at which time her blood pressure was said to have been normal. Physical examination revealed a well-nourished, well-developed female with moderate funnel chest. Blood pressure was 140/92 mm. Hg. There was no cardiac enlargement. A grade 1 mitral systolic murmur was present. The remainder of the physical examination and chest fluoroscopy were not remarkable. An electrocardiogram was normal.

When seen in April, 1954, she complained of shortness of breath and epigastric fulness that occurred after meals and was aggravated by all forms of fat. Review of systems revealed fatigue and shortness of breath on minimum exertion. Physical examination was negative with the exception of grade 1 hypertensive retinopathy, blood pressure of 170/110 mm. Hg, and tenderness in the right upper quadrant. A Graham-Cole test showed a nonfunctioning gallbladder, and cholecystectomy was recommended but declined. The patient was started on therapy with Raudixin, 100 mg. twice a day, and Cholan HMB with phenobarbital (dehydrochloric acid, homatropine methylbromide, and phenobarbital).

She was next seen in September, 1954, during an attack of gallbladder colic. She was still taking Raudixin, 50 mg. twice a day, but had stopped taking Cholan HMB. Blood pressure was 150/80 mm. Hg. She was admitted to the hospital and cholecystectomy was done on Sept. 7, 1954. On the third postoperative day Raudixin therapy was started again. The following morning multiple premature ventricular contractions were noted. These became progressively more severe, and Raudixin therapy was discontinued on the fifth postoperative day when they persisted despite administration of quinidine sulfate, 0.2 gm. four times a day. The following two days, no premature ventricular contractions were noted, and Raudixin was administered for one day. Multiple premature ventricular contractions recurred with moderate subjective distress. Raudixin therapy was discontinued, and the premature ventricular contractions again disappeared. The postoperative course was otherwise uneventful, and a one month follow-up showed no recurrence of the premature ventricular contractions. Blood pressure remained in the range of 140/80 mm. Hg.

CASE 4.—A 56-year-old female was first seen in March, 1952, with neuropathy of facial nerve (Bell's palsy), at which time her blood pressure was 150/100 mm. Hg. In the three months that followed she was seen on four occasions for minor complaints, and her blood pressure ranged from 140/90 mm. Hg to 150/100 mm. Hg. In September, 1953, she was seen for routine examination, and blood pressure was found to be 220/120 mm. Hg. An electrocardiogram was within normal limits. She was asymptomatic at this time. Raudixin therapy, 100 mg. twice a day, was started in November, 1953, for several weeks without apparent results and was discontinued. In Feb-

ruary, 1954, her blood pressure was 190/170 mm. Hg. A test for pheochromocytoma with phentolamine (Regitine) was negative. Raudixin therapy, 100 mg. twice a day, was again started, and blood pressure fell to 160/100 mm. Hg one month later. Therapy was continued, and on Sept. 1, 1954, blood pressure was 160/100 mm. Hg. On Nov. 1, 1954, the patient felt faint while shopping and complained of fluttering in the chest. Blood pressure was 120/80 mm. Hg, and an electrocardiogram showed multiple unifocal premature ventricular contractions. Raudixin therapy was discontinued, and the patient was started on quinidine sulfate therapy, 0.2 gm. four times a day. Examination two weeks later showed her blood pressure to be 180/100 mm. Hg. The patient was asymptomatic. There were no premature ventricular contractions.

COMMENT

Currently available preparations of Rauwolfia serpentina may be divided into three general groups: the crude root (Raudixin); alkaloidal extracts containing the alseroxylon fraction (Rauwiloid and Rautensin); and the single alkaloid, reserpine (Serpasil, Sandril, Reserpoid, Serpiloid, and Rau-Sed). We have used the crude root more extensively and for a longer period of time, and it will be noted that all of the above reported cases are instances of its use. However, we have seen several cases, somewhat less well-defined than the above, in which the use of the single alkaloid, reserpine, has apparently produced similar toxic reactions.

We are unable to determine the percentage incidence of such toxic reactions but suggest that it may not be uncommon. Explanation of the etiology or mechanism of production is problematical, but it is interesting to speculate on the possibility that the bradycardia may allow a so-called irritable focus in the ventricle to become manifest, since most of our patients had organic disease. The possibility of sensitization of the myocardium would be of greater moment and suggests that caution should be exercised in the use of this drug in patients with arrhythmias, myocardial infarction, and severe cardiac damage.

SUMMARY AND CONCLUSIONS

Preparations of Rauwolfia serpentina are being frequently used in hypertension and other conditions. According to the present literature, toxic reaction is infrequently manifest and usually benign. In four cases in which the patients were given Raudixin, a preparation of the crude root, the drug apparently produced premature ventricular contractions. We suggest that the drug be administered with caution in cases of cardiac disease.

"PRECORDIAL CATCH," A NEGLECTED SYNDROME OF PRECORDIAL PAIN

Albert J. Miller, M.D.
and
Teodoro A. Texidor, M.D., Chicago

During the last two years we have become increasingly aware of a syndrome of left-sided anterior chest pain in young healthy individuals. There is much literature on the differential diagnosis of precordial pain, but we have been unable to find any clear-cut references to the relatively common symptom complex here discussed, which we have termed "precordial catch." The following case history presents its essential features.

REPORT OF A CASE

A 24-year-old housewife complained of recurrent attacks of severe left anterior chest pain. The pain, described as sharp and knife-like, was felt just below the left breast. It had occurred four times in the preceding two days. The first episode was typical. The patient was relaxed in an easy chair watching television when she suddenly experienced a sharp, severe pain under the left breast. This pain remained localized and caused her to hold her breath. Attempts to breathe were associated with aggravation of the pain, "as if something were catching" when she attempted an inspiration. Assuming an upright posture, with the shoulders thrown back, eased the pain somewhat. Finally, after an estimated minute or two, she forced a deep inspiration in spite of the pain. This inspiration was almost immediately associated with complete relief from the pain, though a vague ache persisted in the anterior left chest for a short time thereafter.

The patient's history was totally negative except for the usual childhood diseases. Physical examination revealed no abnormalities. In particular, there was no tenderness over the left anterior chest. The blood pressure was 100/70 mm. Hg. The pulse rate was 70 per minute, with a regular cardiac rhythm. An electrocardiogram showed a sinus rhythm and was within normal limits. The heart was "electrically vertical" in position. Cardiac fluoroscopy revealed a vertically placed heart with no evidence of chamber enlargement. The lung fields were clear. A chest x-ray was negative.

One of us (A. J. M.) has had similar bouts of pain on rare occasions. The pain is sudden in onset, is severe, and is localized above the cardiac apex (fifth intercostal space within the left midclavicular line). It has always occurred at rest or during mild activity and invariably has been associated with a "slouched" posture. The immediate reaction to the pain is a suspension of breathing in midrespiration or in expiration, though the pain itself has always come at or near the peak of an ordinary inspiration. Breathing is then confined to shallow chest excursions. This always eases the pain; attempts to take a full inspiration aggravate it. Assuming a correct posture tends to ease it. On two occasions forced inspirations have relieved the pain completely. At other times relief occurred after maintaining shallow respiration with the chest in the midrespiratory or expiratory position. At no time has there been an area of precordial tenderness, and at no time has the pain radiated. The total duration of pain has been estimated as from one-half to three minutes. Its frequency has been sporadic, varying from three episodes in one evening to one episode in six or eight months. It has never occurred during exertion.

Ten patients studied in detail ranged in age from 22 to 35 years; there were five men and five women. Eight of these persons were seen in the office, and six came because of concern about their heart or lungs. One man, whose father had died after suffering a period of angina pectoris, was convinced that he suffered from a similar disease. A woman with a history of childhood rheumatic fever and a negative examination was worried that she now had rheumatic heart disease. Two of the 10 patients included in this report were physicians. However, essentially identical histories have been obtained from at least five other physicians who have not been

---

From the Cardiovascular Department and the Department of Medicine, Michael Reese Hospital.

examined or studied. These latter histories were volunteered during informal discussions.

The pain has been variously described by different patients. The adjectives used include "knife-like," "piercing," "burning," and "sharp." All 10 of the patients stated the pain to be severe. Two of them suggested that "it is as if something catches," and most of the other patients have agreed that this is an appropriate description. The sensation of "something being caught" is particularly apparent when a deep inspiration is attempted after the onset of the pain. Shallow respiration with the chest in the midrespiratory or expiratory position is a usual reaction to the pain. At no time has dyspnea been a part of the picture. The association with poor posture or with bending over has been frequent. Some patients have forced inspirations to relieve the pain. Correction of posture has often resulted in some relief, though two patients have reported "inability" to straighten up from a bending position because of the pain. The onset of the pain is invariably during rest or mild activity. The most strenuous activity reported was that by a woman who was bent forward mopping the kitchen floor. One patient developed the pain while raking leaves. Another patient got the pain when he bent forward to get out of his automobile. One patient usually experienced the pain while walking. He would continue to walk at essentially the same pace. However, other patients stated that "freezing" in the position at which the pain came was the usual reaction. All patients experienced the "attacks" more than once, and at all times the pain was sudden in onset.

No patient reported tenderness at the site of the pain, and tenderness was not elicited at any time during physical examination. No nodules or deformities have been palpated. The pain is always at or above the cardiac apex. One of the 10 patients reported a similar pain in the right anterior chest on one occasion. All the patients have been of thin or medium body build. There has been no apparent correlation of the occurrence of these pains with previous illnesses, physical abnormalities, laboratory studies, hyperventilation, or any other factors that are known to at times result in precordial pain. There has been no consistent correlation with upper respiratory infections, preceding heavy exertion, or emotional disturbance. One patient suffered from a chronic anxiety state. Two patients had mild bronchitis, undoubtedly aggravated by cigarette smoking. Five of the 10 patients smoked cigarettes, with 3 of them being rather heavy smokers. One patient had a history of a contusion of the anterior chest wall two years previously in an automobile accident. Another patient with an otherwise negative examination had an incomplete right bundle-branch block on the electrocardiogram.

There have been certain consistent findings that appear worthy of emphasis: 1. All the patients have been of light or medium body build. 2. The pain is severe, sudden in onset, does not radiate, and is regularly located near or above the cardiac apex. 3. The pain occurs at rest or during mild activity and is frequently related in onset to a "bent over" posture. 4. All the patients have been below the age of 35 years, and there has been no particular sex incidence.

COMMENT

It is not our intent to report this syndrome of precordial pain as a new and previously unnoted entity. On the contrary, many of our colleagues have known of the occurrence of such pains and have themselves recognized them to be of no serious consequence. Nevertheless, the literature that we have reviewed (primarily articles on the differential diagnosis of precordial pain) generally ignores what is obviously a common condition and one that has importance in its confusion by some with either heart disease or disease of the lungs or pleura. We are reporting 10 illustrative cases to emphasize the absence of heart, pleural, or pulmonary disease. A careful history readily determines the diagnosis and should avoid any confusion of this condition with underlying organic pathology.

The term "precordial catch" appears to be appropriate and makes no attempt to indicate the etiology of the pain. It is our feeling that the pain most likely arises from the parietal pleura. Though we can by no means completely rule out the chest cage, its musculature, or its innervation as the source of pain, there are certain factors that speak against this possibility. There is no associated muscle tenderness, and there is no local chest deformity. No abnormalities of the spine have been found. The pain is localized and never radiates. It is a severe pain and undoubtedly would be recognized if it occurred on the right of the chest; hence, we consider its unilateral occurrence to be further evidence against its source being in rib, chest, muscle, spine, or intercostal nerve. One may speculate that the pain is essentially precordial because its origin is in some way related to the reflections of the pleura in relation to the heart. There is no evidence to show a cardiac origin.

SUMMARY

A common syndrome of precordial pain in essentially healthy persons has three major aspects: 1. All the patients have been of light or medium body build; they have been below the age of 35 years, and there has been no particular sex incidence. 2. The pain is severe, sudden in onset, does not radiate, and is regularly located near or above the cardiac apex. 3. The pain occurs at rest or during mild activity and is frequently related in onset to a "slouched" or "bent over" posture. This benign syndrome should be considered in any differential diagnosis of precordial pain.

Cerebral Palsy.—The physician responsible for the care of the cerebral-palsied child can scarcely escape the certainty that treating cerebral palsy will never do. The goal must be prevention. A clearer understanding of the mechanisms of neonatal asphyxia needs to be gained by controlled studies of infants with complicated deliveries. It is essential that further data be obtained from a representative variety of obstetrical sources and that follow-up procedures provide for accurate diagnosis of the children under investigation. In a research program of this scope and direction lie some of the most promising leads for the prevention of cerebral palsy.—R. V. Fuldner, M.D., Cerebral Palsy: Where Next? *A. M. A. Archives of Neurology and Psychiatry,* September, 1955.

COUNCIL ON PHARMACY AND CHEMISTRY

PROVISION FOR NOTICE OF CHANGES IN OPERATION

To govern notice of changes in the Council's method of operation, the following paragraph has been adopted by the Council for inclusion at the end of the previously adopted New Program of Operation for Evaluation of Drugs (*J. A. M. A.* **158:**1170-1171 [July 30] 1955):

When changes in the purpose, principles, or procedure of the Council occur, notice will be given in its column of THE JOURNAL.

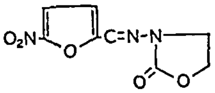
H. D. KAUTZ, M.D., *Secretary.*

NEW AND NONOFFICIAL REMEDIES

Monographs and supplemental statements on drugs that appear in this column have been authorized by the Council for publication and inclusion in New and Nonofficial Remedies. They are based upon the evaluation of available scientific data and reports of investigations.

H. D. KAUTZ, M.D., *Secretary.*

Furazolidone.—$C_8H_7N_3O_5$.—M.W. 225.17.—N-(5-nitro-2-furfurylidene)-3-amino-2-oxazolidone.—The structural formula of furazolidone may be represented as follows:



Actions and Uses.—Furazolidone is a nitrofuran derivative proposed for the treatment of a gynecologic protozoan infection, Trichomonas vaginalis vaginitis. Other members of this class of compounds have been found to have antibacterial properties. The use of furazolidone as an antitrichomonal agent is based upon case reports of four clinical observers employing a powder for vaginal insufflation containing 0.1% of the agent with 0.2% citric acid in 51+% lactose and 48+% dextrose. These observers also used vaginal suppositories for daily and nightly insertion, each containing 0.25% of the agent in a base of 13+% dendropalmitic acid and polyethylene glycol 1000.

A vinegar douche is used 12 to 15 hours after initial drying and insufflation, and each morning after bedtime suppository medication. Diagnostic smears and symptomatic improvement indicate that this form of therapy is frequently effective. However, only a few controlled comparisons with placebo medication have been made and the observations so far do not permit evalution of the effect of furazolidone alone as compared to simple drying of the vagina by exposure to air, the use of acid or plain water douches, or the introduction of the sugars, lactose, and/or dextrose. The mechanical effect of concomitant douching and the addition of known effective agents interfere with the evaluation of any proposed new chemical form of treatment.

Furazolidone has been shown to have low systemic toxicity in experimental animals; however, nitrofuran derivatives sometimes cause skin sensitization after repeated application. So far intravaginal use of furazolidone has not been associated with untoward effects except for the rare occurrence of vulvar edema and pruritus after vaginal insufflation. Further experience is required to determine its potentiality for sensitization of the vaginal mucosa.

Dosage.—Furazolidone is proposed for vaginal insufflation as a 0.1% powder or for vaginal application as a 0.25% suppository. Each insufflation requires 5 gm. of the powder, which is administered two or three times weekly in conjunction with one suppository twice daily for one week and then once daily throughout a complete menstrual cycle including the period of menstrual flow. However, it is not yet possible to estimate the effective dosage of furazolidone alone because it has been employed only in conjunction with other antitrichomonal agents.

Eaton Laboratories cooperated by furnishing scientific data to aid in the evaluation of furazolidone.

Radio-Iodinated (I^{131}) Serum Albumin (Human).—Radio-iodinated (I^{131}) serum albumin (human) is a stable preparation derived from the radioactive isotope, radioiodine (I^{131}), made by mild iodination of normal human serum albumin so that not more than one atom of iodine is introduced per 60,000 molecular weight of albumin. The radioactive component (I^{131}) emits negative beta particles and gamma radiation. The half-life of I^{131} is 8 days.

Actions and Uses.—Radio-iodinated (I^{131}) serum albumin (human) does not significantly differ in physical and chemical properties from the original protein, and when injected intravenously there is no transfer of radioactivity to other blood proteins. Thus the albumin behaves in the body like the normal plasma constituent. As supplied for injection in appropriately buffered isotonic sodium chloride solution, the preparation is adjusted to provide 0.3 to 1 mc. (millicurie) of radioactivity in approximately 10 mg. of human serum albumin per cubic centimeter and to reduce unbound I^{131} to less than 2%. Since there may be a very slow liberation of iodide in such solution, it should be stored at 2 to 10 C and used within 4 weeks from the date of preparation.

After intravenous administration, complete mixing with the circulating blood occurs within 10 minutes. About 90% of the administered dose remains in the plasma at the end of one hour, and equilibrium between the blood and lymphatic systems is complete within 7 to 13 hours. It may appear in the spinal fluid 5 days after intravenous injection. During the first day after administration, 5 to 15% of the radioactivity is excreted in the urine (mostly as sodium radioiodide) and about 5% is taken up by the thyroid; this apparently represents free radioiodine liberated by metabolic processes. It is estimated that 25 to 50% is eliminated during the first week. The urine is the chief route of elimination of radioiodine; the liver does not participate in its excretion. Metabolic studies reveal that detectable amounts remain in the blood and lymph up to 6 days, but smaller amounts may remain for several weeks.

Radio-iodinated (I^{131}) serum albumin (human) is useful as a diagnostic aid for tracer studies in the determination of blood or plasma volumes, circulation times, or cardiac output, and as an adjunct to other diagnostic procedures in the detection and localization of brain tumors. Its use for determination of circulatory volume and time or for the measurement of cardiac output is based upon the principle of dilution of tagged albumin in the normal albumin pools of the body. In the determination of blood or plasma volumes, the preparation is diluted with normal saline solution to a concentration of 2.5 to 3 μc (microcuries) per cubic centimeter, and an aliquot of this solution is removed for use as a standard. The desired dose then is injected into the antecubital vein and samples of blood, immediately heparinized after withdrawal, are taken from the opposite arm 10 to 30 minutes later. Diluted to standard volume, radioactivity of the blood is estimated with a suitable gamma ray-sensitive counter and calculated against that of the standard. When plasma volume is desired, the blood sample is centrifuged before dilution and the supernatant plasma counted after separation and thorough mixing. A technique for counting dried samples also may be employed for determination of either blood or plasma volumes. When repeated determinations are carried out on the same patient, it is necessary to measure the base-line residual radioactivity before injecting a new dose of the tagged albumin; this is subtracted from the activity of subsequent samples before the final calculation is made. The use of radioiodine for blood or plasma volume determinations does not interfere with the simultaneous employment of a pure beta ray-emitting radioisotope for tagging red blood cells in the determination of red cell volume. In the determination of blood circulation times, radioiodinated serum albumin (human) injected peripherally is used in conjunction with a scintillation counter and appropriate electronic recording device. The elapsed circulation time for various pathways (arm to arm or leg, arm to heart, heart to arm) may be obtained by proper placement of the counter at the desired endpoints. Separate counters also may be placed so as to obtain the elapsed time over consecutive segments of the same vascular pathway. Cardiac output also can be measured with radioiodine, using a special technique involving an instrumentation system for continuous recording of radioactivity.

Subject to the dosage limits indicated in the dosage statement, the use of radio-iodinated (I^{131}) serum albumin (human) as a tracer substance involves minimal radiological hazard because of the small amount of activity ordinarily required for repeated studies of blood volume, circulation time, or cardiac output, and the infrequent use of the larger amount that is required for the detection and localization of brain tumors. In view of the gradual metabolic release in the body of small amounts of radioiodine that may be taken up by the thyroid, however, it is advisable to block uptake of radioisotopic iodine and possible damage of the gland by the prior oral administration of strong iodine solution (Lugol's solution). Because of prolonged retention of injected serum albumin in the blood, the possibility should be borne in mind of radioactive contamination of hospital equipment used for subsequent bleeding or surgical procedures performed within the first few weeks after the prior administration of radioiodine. Although some evidence is available to indicate that the immunologic nature of human serum albumin is not altered by iodination with radioiodine, physicians also should be alert to the possibility of allergic reaction in patients receiving subsequent doses several weeks after an initial dose.

Dosage.—Radio-iodinated (I^{131}) serum albumin (human) is administered intravenously. The volume to be injected is determined on the basis of the dilution required to provide the desired radioactive dose from an isotonic sodium chloride solution with an assayed activity between 0.3 and 1 mc. per cubic centimeter. The stated radioactivity assay of solutions at the time of shipment should be corrected for decay prior to administration, in accordance with a table of conversion factors based on the half-life of radioiodine.

For the determination of blood and plasma volumes, the dose ranges from 3 to 60 μc depending on the radiosensitivity of the counting equipment used. For the determination of blood circulation times, the dose ranges between 5 and 60 μc per pathway measured, depending on its vascular length and the sensitivity of the recording apparatus. Similar doses may be adequate for the determination of cardiac output. The dose should be kept as small as possible and should not exceed 200 μc in any one week. Approximately 2.7 μc per kilogram of body weight integrated over a one week period will deliver 0.3 r, which is the tolerance for one week. A single dose of 200 μc can be given at one time, if no more is used for at least one week.

As an adjunct in the detection and localization of brain tumors, a dose of 5 μc per kilogram of body weight may be sufficient when counting is done with scintillation counters or bismuth cathode Geiger-Muller tubes; if counting is to be done with the conventional Geiger-Muller tube, a somewhat higher dose may be desirable, but this should not exceed 500 μc (7 μc per kilogram of body weight in a patient weighing 70 kg.). After intravenous administration of the appropriate dose, a period of 20 to 24 hours is allowed to elapse before systematic scanning of the skull is begun. Serial counts may be made to verify initial counts up to 40 to 48 hours. If a repeat localization study is indicated, a second dose should not be administered sooner than 30 days after the first dose.

Abbott Laboratories cooperated by furnishing scientific data to aid in the evaluation of radio-iodinated (I^{131}) serum albumin (human).

FIFTIETH ANNIVERSARY OF THE COUNCIL ON PHARMACY AND CHEMISTRY

This year marks the 50th anniversary of the Council on Pharmacy and Chemistry. The Council is a standing committee of the Board of Trustees of the American Medical Association, created and organized in 1905 as an advisory body to provide authoritative and unbiased information on drugs. Since its inception, the Council has endeavored to fulfill this function through the dissemination of information designed to encourage rational therapeutics. In the half-century since its establishment, the Council has met the challenge of changing conditions and has sought to keep abreast of the advancement of knowledge in the field of drug therapy. Earlier in this anniversary year, a new program of operation designed to render a better service to the medical profession was instituted.[1] The occasion is thus particularly appropriate to highlight the services and expanded activities of the Council.

The Council's best known book publication, New and Nonofficial Remedies, revised annually since 1907, provides descriptions of the actions, uses, and dosage of new drugs and has achieved the status of a scientific reference on this subject. Monographs on new drugs, regularly submitted to the Editor of The Journal for publication in a special column, provide up-to-date information for subscribers of The Journal and serve to supplement annual editions of the book. The Council issues a companion book publication, the Epitome of the Pharmacopeia of the United States and the National Formulary, which summarizes the recognized uses of older established medicinal substances and which also has been revised periodically to reflect changes in these official publications. The publication of Useful Drugs was discontinued after the appearance of the 15th edition in 1952, because of the limited demand for a book that described a selected list of drugs from the two foregoing publications. The Council has also sponsored the publication of "Glandular Physiology and Therapy" and "Fundamentals of Anesthesia." Revised editions of these books were published in 1954.

To meet a need for encouraging coordinated and improved methods in the clinical investigation of drugs, a standing committee of the Council, designated the Therapeutic Trials Committee, was established in 1945 and renamed the Committee on Research in 1950 in order to broaden the base of its activity. The Committee has sponsored a large-scale coordinated clinical trial of steroids in management of mammary cancer. Reports have been published on the results of such studies, as well as on the criteria for clinical testing of certain other classes of drugs and proposed methods for investigating the efficacy of therapy in certain diseases. This Committee also is currently active in developing procedures for centralizing information concerning unsuspected adverse reactions to drugs.

In 1950 the Council established a standing Committee on Pesticides to obtain, analyze, and disseminate information on the hazards of pesticidal chemicals and methods for avoiding or combating toxic exposure to such agents. A third standing committee of the Council, the Committee on Toxicology, organized at the beginning of this anniversary year, is investigating the problem of accidental poisoning from ordinary household medicines and chemicals.

Commemoration of the Council's 50th year would be incomplete without a tribute to the individual members of the Council, its standing committees, and numerous consultants, without whose unstinting and unremunerated assistance the broad program of the Council could not be implemented. The support and comment of the rank and file of A. M. A. members also have been important to the Council in gauging the kind and amount of information on drugs that is needed in meeting the everyday problems of physicians. It is especially fitting to give individual recognition to a charter member of the Council who has served continuously in a most active capacity since its first meeting on February 11, 1905, and as its Chairman since 1936: Torald Sollmann, M.D., D.Sc., professor emeritus of pharmacology and materia medica, Western Reserve University School of Medicine. *His foresight, leadership, and guidance have made possible many of the achievements of the Council and exemplify the unselfish devotion implicit in its motto: Non sibi sed medicinae.*

REPORT ON MEDICAL PREPAYMENT PLANS

In this issue of The Journal (page 1370) is a progress report from the Commission on Medical Care Plans. It was presented to the House of Delegates of the American Medical Association, and the action of the House will be reported in the abstracted proceedings that will be published in the next several issues of The Journal. The report is printed almost in its entirety in this issue; all that is missing is an exhibit on the questionnaire to be sent to miscellaneous and unclassified plans and a map of the Blue Shield and Medical Society and related plans in the United States. This latter material has been summarized in the text. This is an informative and significant report.

The Commission was appointed by the Board of Trustees in November, 1954. Consisting of 15 members, it has as Chairman Dr. Leonard W. Larson. The survey in process by the Commission includes medical, lay-sponsored, and industry plans and provides information on idemnity insurance plans, prepaid free choice service or full payment plans, prepaid combination indemnity-service plans, prepaid closed-panel plans, noncontributory closed-panel plans, and noncontributory free choice plans. The plans are being studied to permit determination of the history and development of each, the relationship between the plan and the physician, the relationship between the plan and the patient, the extent of coverage of each throughout the United States, and other pertinent data.

---

[1] New Program of Operation for Evaluation of Drugs, report of the Council on Pharmacy and Chemistry, J. A. M. A. **158**: 1170-1171 (July 30) 1955.

The growth of voluntary medical care plans in the United States has been phenomenal, and the American Medical Association has endorsed the principle of these plans as a means by which people may cover all or part of their professional costs of illness and or disability. This development is said to raise several searching questions for the medical profession; for example: What effect, if any, do these plans have on patient-physician relationship? Are there plans in which a participating physician violates the principles of medical ethics? Will the plans encourage the corporate practice of medicine?

There are many facets to the study to be explored by the Commission, but, briefly presented, the objectives of the study can be stated as the determination of the nature and methods of operation of the various types of plans through which persons receive the services of physicians, the effect of these plans on the quality and quantity of medical care provided, and the legal and ethical status of the arrangements used by the various plans. Four committees consisting of members of the Commission have been appointed to consider the different areas of study. The results of the studies so far conducted are evident in the Commissioner's report in this issue of THE JOURNAL. It represents a vast amount of work and, as a progress report, is an invaluable source of information. It serves well as a guide for the studies remaining to be done.

WHERE EXPECTED LONGEVITY IS GREATEST

Often the opinion is heard that the healthiest people in the United States live in heavily populated areas where hospitals, physicians, and other health facilities and personnel are plentiful. Recently published data on the expectation of life, particularly at birth, in each of the 48 states for 1949-1951 refute this popular notion, especially for white males.[1] The statistical department of the Metropolitan Life Insurance Company has assisted the National Office of Vital Statistics of the Department of Health, Education, and Welfare in the preparation of life tables for each state. All the tables, including those for nonwhite males and females, will be published soon by the National Office of Vital Statistics.

The six states with the highest expectation of life at birth for white males for 1949-1951 were: South Dakota, 68.4 years; Nebraska, Minnesota, and Iowa, 68.2 years; Kansas, 68.0 years; and North Dakota, 67.9 years. The expectation of life at birth for white males in the United States was 66.3 years. In 1939-1941 the six leading states for white males were Nebraska, South Dakota, Minnesota, Iowa, North Dakota, and Kansas. Thus it is obvious that white males of these sparsely settled states still enjoy comparatively low mortality. The only changes apparent in the figures cited above are (1) South Dakota has replaced Nebraska as the leader, and (2) Kansas and North Dakota have exchanged ranks.

It is not possible to say that longevity will actually be greatest among the white males of these six states, because expectation of life is an actuarial computation based upon the mortality rates at all ages in three specified calendar years. This computation, strictly speaking, is not a forecast of the mortality that will prevail during the entire lifetimes of the babies born in each of these six states in the specified three calendar years. These favorable mortality records among white males in these six states must be attributed, in part, to the strong North European strains in the population and favorable selection factors in migration. The number of miles that many people in these states must travel to visit a physician or become a patient in a hospital might be considered a health hazard by many urban dwellers, but the people in the West North Central region of the United States have developed a way of life that makes them well adjusted to these spatial conditions.

Nebraska retained its leadership in life expectation at birth for white females with 74.0 years as compared with 72.0 years for the entire United States. Oklahoma, Florida, Iowa, Kansas, and South Dakota follow with 73.8 to 73.6 years. A more general observation is that the state variations in longevity as indicated by expectation of life at birth were less in 1949-1951 than they were in 1939-1941. The leaders in expectation of life at age 25 were South Dakota, Nebraska, and Iowa, with 46.8 years for white males. The leading states for white females at age 25 were Oklahoma, Nebraska, Florida, Arkansas, Kansas, Iowa, Texas, South Dakota, and Utah, ranging from 51.8 years to 51.1 years. The states in which the people at age 65 had the greatest expectation of life were Arkansas, Florida, and Oklahoma for white males and Florida, Arizona, Arkansas, Oklahoma, and Texas for white females.

The variations in expectation of life in 1949-1951 at these three selected ages were less marked, of course, among the nine regions than among the 48 states. The West North Central region (Minnesota, North Dakota, South Dakota, Iowa, Nebraska, Missouri, and Kansas) had the highest expectation of life for white males at birth (67.8 years) and at age 25 (46.4 years), but the West South Central region ranked first at age 65 (13.4 years versus 13.3 years). For white females the West North Central region had the highest expectation of life at birth, 73.3 years; at age 25 its 50.9 years ranked it second to the West South Central region with 51.2 years; at age 65, however, it was outranked by a small margin by the West South Central, Mountain, and Pacific regions. In 1939-1941, the West North Central region ranked first in expectation of life at birth, at age 25, and at age 65 for white males; and first at birth, first at age 25, and tied for second at age 65 for white females. These data for the nine regions, as well as those for the individual states, should remove all doubt about where the expectation of life is and has been the highest, particularly at birth and at age 25.

ORGANIZATION SECTION

REPORT TO THE HOUSE OF DELEGATES

SUPPLEMENTARY REPORT OF BOARD OF TRUSTEES: PROGRESS REPORT OF COMMISSION ON MEDICAL CARE PLANS

BACKGROUND

In order to more fully appreciate the reasons for the appointment of the Commission on Medical Care Plans and to establish a framework of reference for its activities, it may be helpful to underscore briefly the conditions that have given rise to its formation.

The social and economic changes of the past two decades brought about by a depression and two wars have involved every institution and organization in community life. It is important to understand why and how these changes have occurred and how they have influenced the thinking of the citizens of our country. It is important to recognize why the medical profession has, and must continue, to assume a continuing and aggressive leadership in all developments which affect its interests and those of the people it serves. For, unless it is able to provide the guidance and the stimulus for continued improvement in the quality and quantity of medical care for the American people, it will find its voice drowned out by the violence of a force that feeds on expediency or actual existing needs. The issue of quality and quantity of medical care has emerged from our experiences over the past 20 years as one of the major popular issues of our time. The passage of events has also witnessed the growth of voluntary medical benefit programs on a scale which could not have been foreseen.

OBJECTIVES

In the interests of public health, the American Medical Association has encouraged the development of voluntary prepayment plans while attempting to uphold the standards of the profession and to protect the public from unsound plans. However, many programs have grown at such a pace and created questions and problems involving physician-patient relationships and the Principles of Medical Ethics which require study and reappraisal. The American Medical Association is now confronted with a number of basic questions of great concern to the profession. The objectives of the Commission, therefore, are to inquire into (1) the nature and methods of operation of the various types of plans through which persons receive the services of physicians; (2) the effect of these plans on the quality and quantity of medical care provided; and (3) the legal and ethical status of the arrangements used by the various plans, including (*a*) What effect, if any, do these plans have on the traditional patient-physician relationship? (*b*) Does the introduction of a third party in this relationship tend to disturb it and result in an inferior quality of medical care? (*c*) Are there plans in which the participating physician is violating the Principles of Medical Ethics? (*d*) Will the plans encourage the corporate practice of medicine, especially by hospitals? (*e*) What is the proper relationship, if any, between the medical profession and all these third party financial mechanisms?

FORMATION OF COMMISSION

On Nov. 29, 1954, the Board of Trustees approved the formation of the Commission on Medical Care Plans. The 15-member Commission [*] subsequently appointed by the Board was directed to undertake a study for the purpose of determining whether the various types of medical care plans are being utilized to their greatest degree in promoting the availability of health services and whether, at the same time, they are being so conducted as to protect the public and the proper interests of the medical profession. The formulation of the Commission's objectives was contained in a study outline approved by the Board of Trustees in December, 1954, and adopted by the Commission at its first meeting on Feb. 3, 1955. It contained three basic purposes of the Commission's study that have served, and will continue, to guide it in its deliberations.

CURRENT ACTIVITY

The Commission has met on two occasions since its appointment to consider the many problems assigned to it. It has delineated the areas of study through which it hopes to be able to arrive at recommendations and suggested courses of action. The staff of the Commission has been instructed to carry out a number of specific assignments. These include a directory of medical care plans, a compilation of policy statements of the American Medical Association, as well as the decisions and opinions of the Judicial Council, and other material and data covering the specific areas discussed in the following material. The staff has already begun several research projects, the results of which will assist the Commission in its determinations, and it has projected further activity based upon the outcome of its current research efforts. Nine groups of materials have been assembled for study and apportioned among four committees comprised of members of the Commission. This procedure will enable the Commission to benefit from the advice and experience of all its members, and thereby proceed at a faster pace in carrying out its responsibilities. The following is a listing of the committees of the Commission and the areas of study assigned to them.

Areas of Study Under Consideration	Committees
Miscellaneous and unclassified plans Student health services	H. Russell Brown, M.D., Chairman John S. Conway, M.D. F. J. Elias, M.D. Leo Price, M.D.
Medical society and related plans including Blue Shield Private insurance programs	Percy E. Hopkins, M.D., Chairman E. J. Faulkner Jay Ketchum Norman A. Welch, M.D.
Industry programs providing non-occupational medical care Occupational disability programs —workmen's compensation	William P. Shepard, M.D., Chairman David B. Allman, M.D. H. Gordon MacLean, M.D.
Policy statements of the House of Delegates Judicial Council decisions relative to pertinent sections of Principles of Medical Ethics Enabling acts and court decisions	Homer L. Pearson, M.D., Chairman Joseph D. McCarthy, M.D. James R. Reuling, M.D.

---

[*] Leonard W. Larson, M.D., Chairman, David B. Allman, M.D., H. Russell Brown, M.D., John F. Conway, M.D., F. J. Elias, M.D., E. J. Faulkner; Percy E. Hopkins, M.D., Jay Ketchum, Joseph D. McCarthy, M.D., H. Gordon MacLean, M.D., Homer L. Pearson, M.D., Leo Price, M.D., James R. Reuling, M.D., William P. Shepard, M.D., and Norman A. Welch, M.D.

Miscellaneous and Unclassified Plans.—Miscellaneous and unclassified plans constitute one of the important areas of study. They represent that group, other than Blue Shield, other than medical society approved, and other than private insurance plans, that provide payment for physicians' services in a hospital, home, office, or clinic. This group of plans, estimated to number between 250 and 300 throughout the country, is of immediate and particular interest. A recent study by the Department of Health, Education, and Welfare summarizes enrollment data and other characteristics of such plans. However, the Commission found that the above study included a substantial number of plans which should be otherwise classified, and therefore has been conducting a thorough search among various sources, including the literature, in order to prepare a complete and definitive directory of this group of plans. A classification code to identify each of the plans by its outstanding characteristics has been developed and is being employed to process the data as it is received. To date, basic information on 212 miscellaneous plans has been secured through the use of questionnaires, and brief descriptions of these plans have been compiled. Table 1 is a census region breakdown by type of plan and enrollment of 206 plans. An analysis has been made based upon 206 of the 212 that supplied enrollment data. About 100 organizations have not as yet returned the Commission's questionnaire, but it is estimated that no more than 50 might eventually be eligible for inclusion in the study. Enrollment information available for the 206 plans reveals that 4,954,344 persons were eligible to receive benefits for physicians' services either in the hospital, office, home, clinic, or a combination of these facilities. The enrollment figure is actually an understatement, since 12 plans with a membership of 314,438 were unable to supply information on the number of dependents covered at the time the questionnaire was completed. It is reasonable to assume, therefore, that the total enrollment of the 206 plans is over 5 million. The census region breakdown as seen in table 1 shows that:

1. Sixty-four plans, or about 32 per cent, of the 206 with known enrollment, with an enrollment of 1,178,295 are either cash indemnity, service (full payment), or a combination of both; 46 plans, or 72 per cent, of this group are indemnity plans. Enrollment in these plans constitutes more than one-eighth (13.6%) of the enrollment in all plans.
2. One hundred twenty-eight plans, or 62 per cent, of the 206 with known enrollment, with an enrollment of 2,386,769, are closed panel plans either open to the general public or limited to a specific industry, union, etc. Enrollment in these plans constitutes a little less than half (48%) of the enrollment in all plans.
3. Fourteen plans, or almost 7 per cent, of the 206 with known enrollment, with an enrollment of 1,389,280 are a combination of cash indemnity/full payment and closed panel plans. Enrollment in these plans constitutes over one-quarter (28%) of the enrollment in all plans.

A breakdown of the 212 plans (table 2) reveals that the largest number of plans are those jointly sponsored by employer-employee. They represent 28% of all types of plans and 15% of all enrollment. However, union-sponsored plans, which represent only 17.5% of all plans, have the greatest enrollment—more than one-third (36%) of all those enrolled in these miscellaneous plans. More than half (58%) or 123 of the 212 plans provide some type of coverage for dependents. Consumer plans rank first, followed by employer-employee and employee plans.

Physicians' services in a hospital are provided by the largest number of plans; 81% of the plans offer this benefit; 64% of the plans provide these services in a doctor's office; 62% offer this benefit in a clinic and in the member's home (table 3).

Table 4 is a breakdown of the 206 plans with known enrollment. The largest number of plans (38) are equally divided in the 2,500-4,999 and the 5,000-9,999 groups; however, the largest enrollment is in the 100,000-499,999 group, and slightly over 3% of all plans (7 in number) account for more than half (52%) of the known enrollment.

Concurrent with the compilation of a directory, the Commission has in process a detailed study schedule which will be sent to all the plans requesting more complete information on their operations, organization, financing, medical service arrangements, facilities, benefits, personnel, policy, and other items. This information will be recorded on IBM and detailed analyses made for further study and evaluation before conclusions are reached and recommendations made to the Board.

Student Health Services.—Student health services consist of arrangements made by colleges and universities to provide for medical service to students. Within the past five years two studies have been made, one by the American Medical Association Bureau of Medical Economic Research, and one by Cornell University, which provide the Commission with what may be sufficiently current information to evaluate the extent and scope of these services. The findings of these surveys will be studied as the Commission proceeds with its work, and recommendations made to the Board. It was the consensus that, although these plans fall within the scope of the Commission's study and merit consideration, the other indicated areas of study are of more immediate interest and of continuing concern. Further activity in this area may be indicated after sufficient progress has been made in the study of other types of plans.

Medical Society and Related Plans Including Blue Shield.—Medical society and related plans number 116 and include an enrollment of approximately 34 million people for surgical benefits and 25 million for regular medical benefits, as of Dec. 31, 1954. Summary descriptions of 86 plans that describe the 116 plans have been prepared and classified. They will serve as the basis of a detailed study which will summarize various characteristics, such as type of plan, benefit schedules, eligibility requirements, premiums, and other contract provisions.

The Blue Shield Commission has made a detailed study of many of the characteristics envisioned in the Commission study, and its cooperation has been requested in supplying the Commission with the summary data it has compiled. It is contemplated that a similar analysis will be made by the Commission with respect to medical society plans other than Blue Shield. This task should be simplified after Blue Shield data has been secured from the Blue Shield Commission, so that a more uniform basis of comparison can be attempted. Upon the completion of this research project, the members of the Commission may be in a better position to offer recommendations.

There are 30 plans in 23 states with an enrollment of more than 10 million in cash indemnity plans; 27 plans in 4 states with an enrollment of over 750,000 in full payment or service plans; and 59 plans in 35 states with an enrollment of 22,750,000 in a combination of indemnity and full payment plans. Included at this time in the 116 plans are 9 plans which are not approved by any medical organization but which are affiliated with, or are extensions of, local hospital benefit plans.

Private Insurance Programs.—Private insurance programs covered approximately 53 million persons for surgical expense, almost 21 million people for regular medical expense, and some 2,250,000 for major medical expense benefits by the end of 1954. Private carriers include such organizations as capital stock, legal reserve mutual, assessment mutual, cooperative assessment insurance companies, as well as fraternal societies. Before initiating its study of the characteristics of these programs, the Commission is presently attempting to prepare a directory of all private insuring organizations in the United States that may have appropriate charter power to assume these risks. The Commission's compilation to date indicates that upwards of 1,400 insurers have such charter power; however, the number of companies actually writing these benefits may be nearer to 500. A recent compilation by a trade magazine reported the premium and loss data for 430 companies relating to such risks as hospital, surgical, and/or medical expense. The same publication identified some 95 additional companies as engaged in writing medical benefit insurance but which did not report separate premium or loss data.

* Analysis based upon 206 out of 212 miscellaneous and unclassified plans providing enrollment data.

In an effort to identify all companies licensed to write various forms of health insurance, the Commission has contacted all insurance regulatory authorities throughout the country as well as the Federal Trade Commission. In addition, representatives of the Health Insurance Council have been requested to supply the Commission with data on private insurance similar to the Blue Shield data compiled by the Blue Shield Commission. The availability of such material will determine the extent of the Commission's ability to evaluate this group of plans and thus provide a sound basis for any appropriate recommendations for the consideration of the Board of Trustees.

Industry Programs Providing Nonoccupational Medical Care.—Industry programs providing nonoccupational medical care have significant import in the total picture. The number of companies providing nonoccupational health services to employees, the volume and scope of medical services offered, and the number of personnel concerned represent many unknown quantities in medical care for workers in industry throughout the country. Both inplant and outplant medical programs, however, are known to range from those which provide only preplacement examinations and first aid for minor illness and injuries to those with rather comprehensive programs for nonoccupational and occupational medical care.

It is important to note that the emphasis on preventive health programs in industry which are paid for and maintained by industry is an outgrowth of workmen's compensation programs in which financial liability for occupational illness and injury was imposed upon the employer. The increasing recognition on the part of management of the need to keep the employee on the job, to reduce absenteeism due to nonoccupational causes, to reduce turnover, to educate the worker in accident prevention and personal hygiene to match the physical abilities of the applicant with the physical demands of the job—all have resulted in the expansion of what was originally conceived as a "first-aid" program into one of diagnostic and preventive care or "health maintenance," as it is popularly called today.

A further expansion of employee health maintenance is, in some instances, noted in the direction of extending health service programs to retired employees. Many of the programs that do exist, and their number is relatively small, are informal; but they reflect the interest on the part of a segment of management to assist the older worker in reducing the impact of medical costs. On a much more informal basis is the occasional rendering of such services to dependents of employees. As in the case of medical services to retirees, the extent and scope of such programs cannot be measured due to the reluctance on the part of program administrators to disclose either the existence or details of such services. However, these programs do exist. The hesitancy to publicize them stems from several causes, among them are (1) the fear that formal recognition would result in their becoming an integral part of collective bargaining, (2) the fear that such recognition might meet with opposition from within the medical profession itself, and (3) the fact that many programs are largely experimental and the actual costs have not yet been determined. Another rapidly expanding medical service among industry is that of executive health examination programs, which afford the executive an opportunity to secure periodic comprehensive diagnostic medical services.

The 1951 survey by the National Association of Manufacturers among 3,589 member companies with employment of 3,312,647 workers is the most recent study of inplant and outplant medical services now available. The total employment in the survey was more than 22 per cent of the average number of workers employed in manufacturing industries during 1950. Inplant dispensaries were reported by 1,878 companies (52.3% of the total) employing 2,897,357 persons (86.9% of the total). An additional 24 companies reported inplant programs built around company hospitals. The likelihood that an inplant dispensary was available increased as the company size increased. Among the larger companies (over 2,500 employees) there were almost three times as many maintaining dispensaries than were reported by the small companies (1-250 employees) (table 5).

Total	212	172	136	127	133

Preemployment examinations, physical examinations upon return to work from sickness or accident, periodic examinations, health counseling, visual, dental, hearing tests, and home visitation programs were among the services most frequently provided. In addition, but no less important, was the on-the-job treatment for minor illnesses to enable the employee to remain on the job. There was also substantial participation in community health programs such as chest x-ray. Other community programs deal with the problems relating to syphilis, cancer, Rh, and to a lesser extent, multiple screening.

More than 5,000 physicians, about 3,400 nurses, and a large number of first-aid attendants were used in the inplant programs covered by the survey. Over half the companies used physicians employed full time, part time, or on a call basis. Table 6 shows companies reporting the number of physicians of each type, and the employees covered.

Since the characteristics of inplant health programs are of interest to the Commission, and since such programs are an integral part of its study, it would be extremely helpful if the total picture of facilities, personnel, types of services rendered, and physician relationships could be determined. Such a study would require an undertaking of major proportions, however. A questionnaire has therefore been sent to the total membership (3,100) of the Industrial Medical Association asking medical directors to supply the Commission with information concerning medical programs for nonoccupational illness. The same questionnaire is also being used to elicit information on workmen's compensation programs.

TABLE 5.—*Companies with Inplant Facilities, Distribution by Size*

Size Group	Percentage with Dispensaries
All companies	52.3
1- 250	30.7
251- 500	67.1
501-1,000	81.3
1,001-2,500	87.0
Over 2,500	89.1

TABLE 6.—*Physicians in Inplant Programs*

Employment of Physician	No. of Companies	No. of Physicians	No. of Employees
Full time	172	462	1,496,677
Part time	613	1,186	2,038,623
Call basis	1,725	3,367	1,521,384

The Commission also has available to it for study 10 detailed case studies. Hitherto unpublished, these studies of company medical programs contain a variety of examples not only of types of medical programs and scope of services, but, more important, of the relationships that exist between industrial physicians and general practitioners in the community. These are of particular interest in that they contain elements of professional and physician-patient relationships that may require clarification. This material, together with the results of our special survey, will enable the Commission to examine more fully the problem areas in this field of study and to arrive at possible recommendations. An observation worth noting at this time is that the successful operation of many of these programs served as guides for the establishment of so-called union health centers. The Commission is studying union health centers under Miscellaneous and Unclassified Plans.

Occupational Disability Programs—Workmen's Compensation.—The administratioin of medical and rehabilitation aspects of workmen's compensation has probably been more sharply criticized both within and without the medical profession than any other aspect of the program. With a few notable exceptions the medical profession has not concerned itself with workmen's compensation medical practices, despite the size and implications of the program. It is estimated that 21% of all accidental injuries in the United States are occupational. Disabling work injuries result annually in 16,000 fatalities, 91,000 permanent disabilities (of which 1,600 are "total"), and almost 2 million temporary disabilties.

Medical care plans for occupational disability include such things as professional services and hospitalization, and are available to an estimated 39 million employees in 54 workmen's compensation jurisdictions. In 1953 medical care for accidental injuries was unlimited in 36 jurisdictions. In the remaining 18, medical care was limited in time and/or amount. Time limitations ranged from 90 days in Alabama to two years in Michigan. Limitations in costs ranged from $225 in Pennsylvania to $2,500 in Kentucky, with the majority falling below $1,000. In general, medical care plans for occupational diseases in the 50 jurisdictions in which they were covered were limited either to specified diseases and/or time or amount. Artificial appliances were furnished in 49 jurisdictions although 9 limited this by including these costs in the total amount allowed for medical care. Medical costs usually represent 30% of total losses or 19% of the total amount expended by employers to insure or self insure their risks (1952 estimated medical costs—260 million dollars).

The major issues today are: 1. Choice of Physician. In all but a handful of jurisdictions this right is vested in employers and strictly exercised. Since the majority of employers are insured with private carriers, this right is usually transferred to them. The bulk of workmen's compensation medical practice has fallen into a few and not always the best hands. The result has been strained professional and patient relationships and the obvious inconsistency with organized medicine's policies in all other areas of medical care. 2. Supervision of Medical Treatment. Little or no supervision is provided by administrative agencies either through lack of authority or facilities. Less than half have a medical department and most not even one full-time physician. In the case of insured employers, claim adjusters have this responsibility. There are indications that the industrial relations departments of self-insurers are the dominant factors, even though professional personnel are available. By and large, supervision is in the hands of laymen, employed at levels a considerable distance from policymaking.

3. Supervision of Medical Costs. In 21 jurisdictions official fee schedules are used. These have been developed over the years by administrative agencies with participation in most instances by state medical societies. Although most agencies have the power to set fees, few do so except in disputed cases. Self-insurers and insurance carriers control costs by the simple expedient of not using physicians whose charges are out of line with what they are willing to pay, regardless of the quality or amount of the service. A study of medical losses incurred by insured employers over a 10-year period in 39 jurisdictions has been made available to the Commission for its study (tables 7, 8, and 9).

4. Medical Testimony. Aside from legitimate differences over medical theory, there is increasing use of oral testimony as opposed to acceptance of written reports because of questionable scientific basis for physicians' opinions which can be disclosed only by cross examination. Here, too, the bulk of the work is in the hands of a few, known as "employer or employee doctors." 5. Rehabilitation. Although the advantages of such a program are generally recognized, progress in the field of

workmen's compensation has been considered slow. Much of the failure has been attributed to lack of cooperation by physicians, although a number of other factors are equally, if not more so, responsible.

* Data supplied by National Council on Compensation Insurance.

† Premiums earned: annual averages and period increases; losses and indemnity incurred: annual averages, period increases, and ratio to premiums earned and losses incurred.

‡ x in column, 1—physician may be selected by employee; 2—medical benefits limited in time and/or amount; 3—official fee schedule; blanks—physician selected by employer, unlimited medical benefits, and no official fee schedule.

Selected statutory provisions related to coverage and medical benefits under workmen's compensation have been prepared (tables 10 and 11). Additional data are needed to test the validity of some generally accepted concepts and especially to provide information not presently available on self-insurers and some aspects of rehabilitation. Some of these topics are covered in the questionnaire sent to 3,100 members of the Industrial Medical Association. It may be possible to develop the remainder by correspondence with stock and mutual carriers associations, administrative agencies and other sources.

Little is known about (1) the coordination of occupational and nonoccupational disability programs, (2) the number and conditions of employment of physicians engaged in workmen's compensation practice, (3) the number of persons receiving medical care for occupational disability under self-insurance programs, (4) the cost of medical care under self-insurance programs, (5) the number and cost of occupational disability cases rehabilitated in public and private agencies.

Two detailed studies by the Council on Industrial Health reflecting the general conditions of medical care and relations under workmen's compensation are also under consideration.

The Board of Trustees has before it certain recommendations from the Council on Industrial Health regarding the issues raised in connection with workmen's compensation. The Commission will consider as part of its study the actions of the Board of Trustees and the House of Delegates with regard to these problems.

Policy Statements of the House of Delegates, Judicial Council Decisions, Enabling Acts and Court Decisions.—The six areas of studies outlined previously encompass the broad range of medical care programs under consideration by the members of the Commission. To these must be added three other spheres of study which are more directly connected with the role of the Association and the medical profession in formulating its attitude toward medical care plans. These three areas present a historical perspective to all of the problems of medical care. They concern themselves with a study of (1) policy statements of the House of Delegates from 1926 to the present date, (2) Judicial Council decisions relative to pertinent sections of the Principles of Medical Ethics from 1847 to date, and (3) enabling acts and court decisions that have a bearing on the medical care programs under study.

A thorough analysis of the body of material in each of the foregoing categories is a necessary part of the work which the Commission is undertaking. These compilations have already been made and, based on preliminary study, have dictated the necessity for additional study that has yet to be carried on. Steps have been taken to correlate the decisions of the Judicial Council and the House of Delegates with the relevant sections of the

FOOTNOTES:

(1) Table omits public employment except in United States jurisdiction.
(2) Virtually all jurisdictions also exclude casual employment. Some minor exempt categories are omitted to avoid excessive detail. In most jurisdictions exempted employers may voluntarily choose coverage, but unlike "nonelection," failure to volunteer does not result in loss of any common-law defenses in damage suits.
(3) Agricultural employers with payrolls of $500 or over are covered in absence of positive rejection.
(4) Exempt unless employed by one employer over 52 hours a week.
(5) Elective for occupational diseases.
(6) Compulsory for coal mining.
(7) None in mining and building.
(8) Threshing and/or other mechanized operations are covered; in South Dakota, limited to commercial farming.
(9) Except when commercially processing agricultural products.
(10) Numerical exception of 4 applies legally to nonhazardous employments but is seldom actually applied owing to comprehensive definition of "hazardous."
(11) Exempt unless employed 48 hours or more per week in cities of 40,000 or more.
(12) Comp., competitive state fund; Excl., Exclusive (monopolistic) state fund.
(13) Includes one or more of the following: vendors or distributors or newspapers, charity workers, outworkers, industrial homework, professional athletes, independent contractors, employees of common carriers, logging, sawmills, turpentine, woodcutters, blacksmiths, clerical workers, stock raising, etc.

SOURCE: Adapted from Somers, H. M., and Somers, A. R.: Workmen's Compensation, New York, John Wiley & Sons, Inc., 1954.

EXPLANATORY NOTES:

It is the purpose of this table to give a general picture of compensation laws; therefore detailed modifications of statutory provisions and administrative practices in individual jurisdictions are not given. While all jurisdictions agree as to the principle of workmen's compensaton, no two of them have exactly the same benefits. The law meets particular conditions. No compensation law covers all employment.

Two general methods are in effect in administering workmen's compensation laws:

1. By the courts in Alabama, Louisiana, New Hampshire, New Mexico, Tennessee and Wyoming; and
2. By commissions, boards or bureaus created by law in all others.

COLUMN A.—Type of Law

Compensation laws are either compulsory or elective. A compulsory law requires every employer within its scope to accept its provisions and to provide the benefits specified. Under an elective law, the employer may either accept or reject the act, but in case of rejection, he loses the three common-law defenses—Assumption of Risk, Negligence of Fellow Employee, and Contributory Negligence. Workmen's compensation laws are Compulsory in 22 states, the District of Columbia, Alaska, Hawaii, Puerto Rico, Federal Employees' Compensation Act and the Longshoremen's Act. Workmen's Compensation laws are Elective in 26 states.

COLUMN B.—Insurance Provided by:

All jurisdictions require the employer either to obtain insurance or to give proof of his financial ability to carry his own risk. Private insurance carriers provide insurance for employers in 41 states, the District of Columbia, Alaska, Hawaii, and under the Longshoremen's Act. Employers may self-insure in 41 states, the District of Columbia, Alaska, Hawaii, and under the Longshoremen's Act. Employers may insure their risks in competitive state funds in 11 states. In 7 states and Puerto Rico, employers must insure with the exclusive (monopolistic) state fund. Benefits are provided under the Federal Employees' Compensation Act by Congressional appropriation.

COLUMN D.—Exceptions from Coverage

Although most acts permit voluntary acceptance of its provisions by any employer, the following employers are exempt (if they wish) under compulsory laws:

1. Employers of less than 2 in 1 state. Employers of less than 7 in 1 state.
   Employers of less than 3 in 9 states. Employers of less than 8 in 3 states.
   Employers of less than 4 in 6 states. Employers of less than 10 in 1 state.
   Employers of less than 5 in 5 states. Employers of less than 11 in 1 state.
   Employers of less than 6 in 1 state. Employers of less than 15 in 1 state.
2. Employers in nonhazardous businesses in 10 states.
3. Employers of farm labor in 38 states, the District of Columbia, and Alaska with modifications in 6 other states.
4. Employers of domestics in 44 states, the District of Columbia, and Alaska with modifications in 2 other states.
5. Employers of employees in specified occupations (other) in 31 states and Alaska.

Principles of Medical Ethics and, further, to list all actions related to the same problem into special categories. This will enable the Commission to determine uniformity (or lack of it) in the approach to specific problems, and to arrive at what may be suitable recommendations with reference to them. It should be pointed out, too, that each committee of the Commission is not only responsible for the areas of study assigned to it, but is also seriously weighing the past actions of the Association as they relate to the specific areas of medical care plans.

TABLE 11.—*Selected Statutory Provisions Related to Medical Benefits Under Workmen's Compensation Laws, January, 1953*

	A.	B. Maximum Time and Amount		C.	D.	E.
Jurisdiction	Physician Selected by	Accidents	Occupational Diseases	Artificial Appliances	Official Fee Schedules	Rehabilitation Available (1952)
Alabama	E	90 days; $500	90 days; $500	Yes (a)	....	....
Alaska	E	2 yr.	2 yr.	Yes	....	....
Arizona	E	Unlimited	Total disability, $500	Yes	Yes	Yes

Michigan	E	2 yr.	2 yr.	Yes	....	....
Minnesota	EE	Unlimited	Unlimited	Yes	....	Yes
Mississippi	E/C	Unlimited	Not covered	Yes	....	Yes
Missouri	E/C	Unlimited	Unlimited	Yes	....	Yes
Montana	E/EE	9 mo.; $1,000	Silicosis only; limited	Yes	Yes	....
Nebraska	E/C	Unlimited	Unlimited	No	Yes	....
Nevada	EE	18 mo.	$750 for silicosis	Yes	Yes	....
New Hampshire	EE	Unlimited	Unlimited	(b)	....	....
New Jersey	E	Unlimited	Unlimited	Yes	....	Yes
New Mexico	E/C	Unlimited	Unlimited	Yes	....	....
New York	*EE/P*	*Unlimited*	Unlimited	Yes	Yes	Yes
North Carolina	E/C	Unlimited	Unlimited, except silicosis and asbestosis, $3,000	Yes	Yes	Yes
North Dakota	EE	Unlimited	Unlimited	Yes	Yes	Yes
Ohio	E/EE	Unlimited	Unlimited	Yes	Yes	Yes
Oklahoma	E	Unlimited	Not covered	Yes	....	....
Oregon	EE/AA	Unlimited	Unlimited	Yes	Yes	Yes
Pennsylvania	E	90 days; $225 plus hosp.	90 days; $225 plus hosp.	Yes	....	....
Puerto Rico	EE/AA	Unlimited	Unlimited	Yes	....	....
Rhode Island	EE/AA	Unlimited	Unlimited	Yes	....	Yes
South Carolina	E	Unlimited	Unlimited	Yes	Yes	....
South Dakota	E/C	20 wk.; $1,000	20 wk.; $1,000	Yes (a)	....	....
Tennessee	EE/P	6 mo.; $800	6 mo.; $800	Yes	....	....
Texas	E/C	91 days med.; 180 days hosp.	91 days med.; 180 days hosp.	Yes	....	....
United States						
Federal employees	E	Unlimited	Unlimited	Yes	....	Yes
Longshoremen	E/C	Unlimited	Unlimited	Yes	....	Yes
Utah	E	Unlimited	Total disability; $1,500	Yes	Yes	Yes
Vermont	E/C	90 days; $1,000	60 days, $300 for silicosis and asbestosis	No	....	....
Virginia	E/C	10 mo.	12 mo.	Yes	....	....
Washington	E/EE	Unlimited	Unlimited	Yes (a)	Yes	Yes
West Virginia	EE/AA	$2,400	$2,400; none for silicosis	Yes (a)	Yes	Yes
Wisconsin	EE/P	Unlimited	Unlimited	Yes	....	Yes
Wyoming	EE	Unlimited	Not covered	Yes	Yes	....

FOOTNOTES:

(a) *Included in total amount for medical care.*

(b) Replacement of artificial members if damaged in accident.

SOURCE: Adapted from Somers, H. M., and Somers, A. R.: Workmen's Compensation, New York, John Wiley & Sons, Inc., 1954.

EXPLANATORY NOTES:

COLUMN A.—Physician Selected by:

In 31 states, Alaska, District of Columbia, Hawaii, and under the Federal Employees' and Longshoremen's Acts, selection of physician is vested in the employer by statutory provision or judicial interpretation; in 19 of these jurisdictions, the carriers appear to assist in the selection made by the employer. Individual employers may permit employees to select the physician or surgeon under certain circumstances in a few jurisdictions (E or E/C).

In 4 states, the employee may select the physician or surgeon from a panel furnished by the employer or carrier. In New York, the panel is established by the county medical societies and any doctor on the panel may be chosen. In Wisconsin, the state medical society issues a list of doctors who will accept workmen's compensation cases, which list is usually adopted as the employer's panel (EE/P).

In 13 jurisdictions (8 of which are exclusive state fund jurisdictions) the employee may select any physician, provided that:

1. In Minnesota, Nevada, North Dakota and Wyoming only initial selection of physician is unrestricted (EE).
2. In Montana and Washington, there are no contractual arrangements for medical care made by employers to the contrary (E/EE).
3. In Ohio, self-insured employers may select the physician, while employers insured in the exclusive state fund must permit their employees to select their own physicians or surgeons (E/EE).
4. In West Virginia, Oregon, Puerto Rico and Rhode Island, the selection is subject to the approval of the administrative agency which may transfer the case to another physician (EE/AA).
5. In New Hampshire, the employee may select "a qualified physician or other remedial care" (EE).
6. In Massachusetts, the employee may accept the services of the physician selected by the employer or select his own (EE).

SUMMARY AND RECOMMENDATIONS

On the basis of the recommendations of each of the committees of the Commission and the thorough discussions that have taken place among all its members, the Commission on Medical Care Plans recognizes even more fully the tremendous responsibility with which it has been charged. It recognizes also the obligation it has to the medical profession and to the public, and therefore feels that it cannot make any final recommendations to the Board of Trustees other than the three indicated below until it has pursued more intensively the areas of study under consideration. It feels that pronounced progress has been made thus far and that its efforts at further objective research and study will result in basic and fundamental recommendations, which it hopes will assist the medical profession and the Association in determining its future role in safeguarding the highest quality of medical care for the American people. For the foregoing reasons, action has been deferred with respect to Resolutions 1 and 11 (1954 Clinical Session) and Resolutions 19, 50, 63, and 68 (1955 Annual Session).

Each of the four committees appointed by the Chairman has presented proposals and recommendations for further study and analysis that have been accepted by the Commission. A mail questionnaire technique is being employed to elicit additional information in several of the areas of study. The continuing collation of existing data will also be of material assistance.

Based upon its deliberations the Commission had three recommendations to make to the Board of Trustees. They were that:

1. The report of the Council on Medical Service presented to the Board of Trustees on May 24, 1955, which included a suggested substitute resolution to Resolution 12 by Dr. James Z. Appel of Pennsylvania (Resolution on Relationship Between Component County Societies and Lay-Sponsored Health and Welfare Plans) be adopted, i. e.:

"WHEREAS, The medical profession is dedicated to the provision of medical care in the public interest; and

"WHEREAS, It is essential in providing the best medical care to the public that the profession be concerned not only with the planning of facilities but also with the maintenance and improvement of standards therein; and

"WHEREAS, The experience of the Council on Medical Service indicates that benefits may accrue to the public by encouraging state and county committee activities in this field; and

'WHEREAS, The profession recognizes that the community has a vital concern regarding the availability and operation of medical facilities; and

"WHEREAS, Medical facilities are being sponsored or established by non-medical groups in some areas; therefore be it

"*Resolved*, That constituent associations and component societies be encouraged to designate committees whose functions may include but need not be limited to:

1. Maintaining continuous studies with respect to existing health facilities as well as needs;

2. Consulting with groups having an interest in health facilities; and

3. Advising groups or individuals interested in sponsoring, establishing or improving health facilities."

2. The Board of Trustees recommend to the House of Delegates that the Constitution and Bylaws be amended to provide that amendments to the Principles of Medical Ethics proposed at a session of the House of Delegates shall be held over until the next session before final action is taken; and that during this period the Judicial Council shall consider such proposed amendments and report to the House of Delegates at the Session at which final action is taken.

3. The Pearson committee of the Commission be authorized to meet with leading figures among the general public in order to obtain their interpretations of the Principles of Medical Ethics. In the opinion of the Commission such a committee would not overlap the activities of the Hess labor-management liaison committee but would, in fact, supplement some of the latter's efforts.

The Board of Trustees, at its meeting on Oct. 23, 1955, voted to adopt recommendation 1 and to refer the substitute Resolution 12 to the House of Delegates; recommendation 2 was approved and referred to the Council on Constitution and Bylaws for consideration and implementation at the Boston meeting, and action on recommendation 3 was deferred until a later meeting.

The Commission wishes to acknowledge the efforts of the headquarters staff in assembling for its use a voluminous and imposing array of materials and data. This exhaustive effort reflects the attitude of the Board of Trustees in assuring the Commission access to all available resources through which its task can be expedited. It is indicative of an awareness of the high priority assigned to this project, as well as the resolve that every effort will be expended to make the Commission's study one that will be a contribution to the medical profession and to the public it serves.

SESSION ON ALLERGY IN SECTION ON MISCELLANEOUS TOPICS, CHICAGO MEETING, 1956

Any member who wishes to present a paper at the Allergy Session of the Annual Meeting to be held in Chicago should write for "Suggestions for Authors of Section Papers" and "Standing Rules of Sections." Abstracts of papers will be accepted for possible inclusion in the program until Jan. 31, 1956. Time and place will be announced at a later date. For information write the Secretary, Lester L. Bartlett, M.D., 550 Grant St., Pittsburgh 19.

CHANGES IN DIVISION OF THERAPY AND RESEARCH

Effective Nov. 5, 1955, the Division of Therapy and Research, by action of the Board of Trustees, was renamed the Division of Councils of Therapy and Research and Dr. Robert T. Stormont was named Director. The Division is composed of the headquarters staff of the Council on Pharmacy and Chemistry, Council on Foods and Nutrition, Council on Physical Medicine, Committee on Research, Committee on Pesticides, Committee on Toxicology, Committee on Cosmetics, Bureau of Investigation, and A. M. A. Laboratories. In addition, Dr. Harold Kautz was designated Secretary of the Council on Pharmacy and Chemistry and Mrs. Veronica Conley, Secretary of the Committee on Cosmetics.

MEDICINE AND THE LAW

HOSPITAL'S LIABILITY FOR NEGLIGENCE OF LABORATORY TECHNICIAN

It has been the opinion of the House of Delegates of the American Medical Association since 1943 that the practice of medicine includes the practice of pathology or, to put it another way, that the practice of pathology is the practice of medicine. Since that time the question has often been raised as to whether or not certain laboratory tests utilized by a pathologist are, in and of themselves, the practice of medicine. One of the very few cases involving this question was recently decided by the supreme court, trial term, New York County, Part XX New York.[1] The case is of interest for both its legal and medical findings.

Mrs. Berg, suffering from rheumatoid arthritis, entered the defendant's hospital in March, 1947, for a course of treatment that involved among other things the administration of 500 cc. of blood. Prior to performing the transfusion, a sample of her blood was sent to the hospital's laboratory and the technician who tested it reported that Mrs. Berg's blood was type A, Rh positive. Pursuant to this report, she was transfused with Rh positive blood, the transfusion being stopped when she started to develop an unfavorable reaction. Mrs. Berg was discharged from the hospital in April. In May or early June she became pregnant and was directed by her family physician to a laboratory in Elizabeth, N. J., for the purpose of determining her blood type and Rh factor. It was then discovered, and later verified, that she was type A, Rh negative.

The infusion of Rh positive blood into an Rh negative female, said the court, causes antibodies to be created, and she becomes sensitized. In the event that such a female should become pregnant with an Rh positive fetus, such antibodies will in all likelihood cause the fetus to have a blood disease known as fetal erythroblastosis, which, when very severe, may result in stillbirth. During the course of Mrs. Berg's pregnancy it was established that the fetus was an Rh positive one, since her titer index (the quantity of antibodies in the blood) rose substantially. She was advised that this increased titer would in all probability be fatal to the fetus. On Dec. 2, 1947, the fetus died, but Mrs. Berg was advised to carry through for the full period. On Dec. 30, 1947, Mrs. Berg was admitted to St. Elizabeth's Hospital in Elizabeth, N. J., where, after an entire day of labor, she delivered a stillborn macerated female fetus. Undoubtedly, said the court, the cause of the stillbirth was the infusion of the Rh positive blood into Mrs. Berg. This wrongful infusion of incompatible blood into the mother created the blood disease of fetal erythroblastosis, which was the competent and producing cause of the macerated fetus.

An Rh negative female has an excellent chance of carrying through uneventfully at least one Rh positive fetus, the court found, assuming, of course, that she has not previously been sensitized by a transfusion of Rh positive blood, which to her would be incompatible; she might even carry through successfully a second and third positive fetus. In this case Mrs. Berg became highly sensitized by the transfusions of incompatible Rh positive blood. This sensitization undoubtedly caused the stillbirth. The result was that she could not thereafter carry through successfully an Rh positive fetus. Because of the circumstances, the attending physician at the delivery found it necessary to use manual pressure upon the abdomen for a much longer period than is usual or customary. This unusual and sustained manual pressure caused various internal difficulties that subsequently required medical treatment and ultimately an operation. Mrs. Berg suffered a cystocele, rectocele, and prolapsed uterus, and she subsequently submitted to a vaginal hysterectomy, thus not being able to become pregnant again.

The evidence, said the court, supported the plaintiff's contention that the laboratory technician was negligent in performing the blood test to determine Mrs. Berg's Rh factor. The defendant made no effort to explain how the mistake occurred but sought to get the plaintiff's witnesses to admit that the Rh positive finding could have been caused by weak or impure serum purchased from outside laboratories. The plaintiff's witnesses were in agreement, and the court found that weak or impure serum would result in an Rh negative finding but could never result in an Rh positive finding if the person being tested was, in fact, Rh negative.

In a letter[2] dated Jan. 24, 1955, to the Committee on Medicolegal Problems, Dr. A. S. Wiener, Brooklyn, N. Y., member of the Committee, in discussing this case said, in part:

> "The fact is that a weak serum will give false negative reactions, so that blood which is Rh positive might be incorrectly diagnosed as Rh negative. On the other hand, an impure or contaminated or nonspecific serum may give false positive reactions so that blood which is Rh negative may be incorrectly diagnosed as Rh positive."

The primary contention raised by the defendant was that, even if the laboratory technician was negligent, it was not responsible for this negligence, because the performance of a test to determine the Rh factor of a blood sample taken from a patient is a medical act and not an administrative one. The court stated that whether the testing of blood for these purposes by a laboratory technician employed in the hospital's own laboratory is a medical act or an administrative one was a question of law and that in its opinion the test performed by the laboratory technician was an administrative act. It was held in this case that the technician was not performing any medical act but was conducting a simple chemical test. In the opinion of the court the act did not involve or require any decision on the part of the technician as to treatment or care of the patient and did not embrace the exercise of judgment as to the nature, character, and symptoms of a disease, the determination of the proper remedy for the disease, or the giving or prescribing of a remedy for the disease. None of these elements was found to be present in the act performed by the defendant's laboratory technician. Accordingly, the court decided that the laboratory technician was guilty of negligence, and judgments were awarded against the defendant hospital in favor of both Mrs. Berg and her husband.

[1] *Berg* v. *New York Society for the Relief of the Ruptured and Crippled,* 136 N. Y. S. (2d) 528 (N. Y., Dec. 30, 1954).

[2] Wiener, A. S.: Personal Communication to the Committee.

A District of Columbia case decided in 1950 [3] and a case decided by the New York appellate division in 1953 [4] were cited in the Berg case as authority for the court's decision. In the former the hospital was held liable for the technician's error, which resulted in transfusion of incompatible blood; in the latter the employer was held liable for injuries to a job applicant by a physician in its medical department in obtaining a blood sample.

PUBLIC RELATIONS

Tomorrow's Citizens Learn Health Responsibilities

Americans today are a lot better informed about good health and about medicine in general than ever before. But what about tomorrow's citizens? Are they learning the essentials of individual good health? And what is equally important—are they learning that they have a vital stake in community health?

Leadership in health education rightfully falls into the domain of the medical profession. Physicians know that their responsibilities to their patients and their communities encompass not only medical service but health education as well. Through speakers' bureaus and health forums, and radio and television programs, physicians are bringing authentic health information to both adults and students. In at least one state, Tennessee, physicians and their wives are incorporating in their educational activities a project designed to instill in the younger generation a feeling of responsibility for community health.

For the past three years the Woman's Auxiliary of the Tennessee State Medical Association has sponsored a statewide Health Project Contest in high schools. Now approved and distributed by the state department of education, the project is designed to bring groups of students together to work toward common health improvement goals in their schools and communities. Individual classes or an entire school may enter the contest by selecting and carrying out a project such as a sanitation survey, an immunization drive, a nutrition program, a public health education campaign, or a similar activity. A $500 savings bond is awarded to the group completing the best project, and a second prize of a $100 bond is given the runner-up. Two representatives of the class, group, or school winning the grand prize receive an expense-paid trip to the annual meeting of the Tennessee State Medical Association to report on their project before the association's house of delegates.

The contest's aim is to teach Tennessee youth the value of good health and to illustrate the value of well-planned group action to the American way of life. In addition, the contest is designed to insure continued enlightened cooperation between the public and the medical profession toward the common goal of healthy and productive living through the wise application of the medical arts and sciences.

The Tennessee State Medical Association in a report on this project said: "Our original contest was of the essay type, and reached the same small group each year without measurably affecting the majority of the students in the schools. We believe, because it is a 'doing' rather than a 'writing' contest, that it gives all the participating students an opportunity to gain a better insight into health problems and to think constructively toward their solution." Encouragement for the contest is supplied by woman's auxiliary members, who urge both teachers and students to take an active interest in the project.

Public Relations Conference Tells 1956 Outlook

"America, '56—What's Ahead for American Medicine" was the theme for the American Medical Association's 1955 Public Relations Conference, held on Nov. 28 at Boston's Hotel Statler, just prior to the Association's Clinical Session. A penetrating discussion of the free enterprise system and the inroads made upon it in recent years by socializers, pinpointed to the interests of the medical profession was held.

At the morning session, A. M. A. President-Elect Dwight H. Murray, Napa, Calif., gave the keynote address, followed by a symposium outlining what is ahead in 1956 in legislation, medical service, and public relations. Erle Cocke Jr., Atlanta, Ga., vice-president, Delta Airlines titled his luncheon address "Where Goes Our Nation?" Congressman Thomas B. Curtis, Missouri, and Leonard E. Read, president, Foundation for Economic Education, spoke on snowballing social security at the afternoon session, and other outstanding speakers, including Massachusetts Governor Christian A. Herter, appeared. Dr. Edward J. McCormick, Toledo, Ohio, past-president of the A. M. A., gave the concluding talk.

The national Medical Public Relations Conference is one of two annual public relations meetings conducted by the A. M. A. as a service to state and county medical societies. The conference is a policy meeting, planned primarily for society officers and committee chairmen who establish public relations policy.

What the Doctor Never Hears

When patients are unhappy or irritated about some experience connected with securing medical care, they rarely take their complaints direct to the doctor. Generally, the physician goes his way unaware of their grievances. Most of these complaints are aired over the bridge table, over lunch, or in any one of a hundred everyday situations. Occasionally, however, some individuals feel strongly enough to write a letter to the editor of their newspaper.

A recent letter of this type, published in the Fresno (Calif.) *Bee,* focuses attention on a doctor-patient relationship problem requiring public relations action by individual physicians. Here is a brief resume of the letter: "I have heard many people remark about the doctors of today spending so little time with you when you go in to see them. They hardly take time to find out what your ailment is before you're whizzed out of the room. . . . I was in a doctor's office the other day waiting and a man said to me, 'I sure hate to go in and see him. Every time I go in he looks like and treats me like a bear.' I told him I have experienced the same thing and have heard others say that they have too. What is wrong, is the doctor angry because I am ill or because I don't come in often enough? I always pay my bill at the time of the office call. . . . The doctor of yesterday was interested in making you well—not getting all the money he could from you."

The good will and friendship of patients are not won in hurried five-minute interviews or with the quick scribbling of a prescription. Often a physician must work hard to cultivate the gentle, interested, and reassuring manner that patients expect. This is no easy task when the physician is feeling the pressures of a busy practice and a demanding schedule. Patients resent being rushed through an interview with the doctor. The physician must give the impression he has plenty of time to listen to each patient's problems.

One physician points out, however, that "the complaint, perhaps minor to the doctor, is major to the patient. Frequently listening patiently and making a careful examination means more to the patient than the drug or treatment prescribed."

Patients want and expect personalized treatment, and here are some suggestions from a number of doctors on how to give that type of "individualized service": First, cultivate a calm, assured manner. Second, show interest in the patient. Third, give evidence of sympathy, yet retain firm control of the interview. Fourth, give your full attention to the patient. People soon lose confidence in the "absent-minded professor" type of physician. And last, take time to listen patiently. With these public relation attitudes in mind, a physician can eliminate the sources of friction that lead some patients to voice their complaints to the world via the columns of the local newspaper.

PRoblem Corner

How can a physician convey to his patients his sincere desire to serve their medical needs to the best of his ability? How can he fully answer their many questions about various aspects of medical service, about hospitalization, and about the cost of medical and related services? How can he explain the relationships of the various members of the medical team in order that his patients understand that complete medical care often is a cooperative thing? How can he best establish himself as his patient's personal physician?

Few physicians today can take time to achieve this kind of understanding with each patient through individual conversations. A number of physicians have written leaflets for their patients in which they attempt to answer some of these questions in advance. These individual doctors' leaflets have been so well received by patients that the American Medical Association has prepared one as a service to its members, which physicians can distribute to their patients to build a better doctor-patient relationship. Entitled "To All My Patients," it is available in quantity free of charge to all members of the Association from the Public Relations Department.

The pocket-sized "To All My Patients" explains the patient's role in obtaining good care and points out that there are many kinds of doctors, but they all have the same goal—provision of top-quality medical service. It discusses briefly consultation, medical fees, bills for other medical expenses, the hospital, and medical insurance. The leaflet opens with these words: "I appreciate the confidence you have expressed in me by selecting me as your physician. I sincerely hope that I can give you and your family the kind of medical service you desire. If you have questions about my services or fees, hospitalization, or other aspects of your care, please discuss them frankly with me. The best medical service is based on a friendly, mutual understanding between a doctor and his patient."

It concludes with this message: "It is difficult for a physician briefly to explain every service necessary in providing good care because each case is different. I sincerely hope this leaflet will give you a better understanding of some of the services you may require. Again, I invite you to talk things over. If we do so, it will help me to become your personal physician in every sense of the word."

MEDICAL NEWS

CALIFORNIA

Lecture on Poliomyelitis.—In the annual lecture series sponsored by University Extension and the University of California Medical School in Los Angeles, "The Epidemiology and Prevention of Poliomyelitis" will be presented by Dr. Edwin H. Lennette of the Viral and Rickettsial Disease Laboratory, California State Department of Public Health, Berkeley, Dec. 12, 7:30 p. m. in the first floor lecture hall (room 13-105) of the medical center.

Personal.—Dr. Lester Adelson, formerly of Cleveland, where he was chief deputy coroner of Cuyahoga County, has been appointed chief deputy coroner of Los Angeles County. His appointment and the charter amendment plan that is expected to result in the reorganization of the department, making the coroner a medical officer, conformed to recommendations by the Los Angeles County Medical Association.——Dr. Wilton L. Halverson has been named by President Eisenhower to the International Development Advisory Board for a two year term. Since his resignation as state director of public health, Dr. Halverson has been chairman of the department of preventive medicine and public health of the University of California at Los Angeles School of Medicine.

Rabies Endemic in Many Counties.—The California Department of Public Health has declared animal rabies endemic in 26 counties on the basis of the increase in reported cases this year, 291 cases (154 in dogs and 126 in wild animals) having been recorded in the first 10 months. This compares with a total of 83 cases (33 in dogs and 43 in wild animals) reported in 19 counties for all of 1954. Rabies currently is endemic in the counties of Alameda, Amador, Butte, Colusa, El Dorado, Fresno, Humboldt, Lake, Los Angeles, Marin, Mendocino, Merced, Monterey, Napa, Sacramento, San Benito, San Joaquin, Shasta, Solano, Sonoma, Stanislaus, Sutter, Tehama, Tulare, Ventura, and Yolo. Local health authorities in the 26 counties will determine, in consultation with the state health department, the nature of control actions required, including the boundaries for quarantine of dogs.

COLORADO

Narcotic Violation.—Dr. George L. Robinson, 1747 Williams St., Denver, pleaded guilty in the U. S. District Court at Denver Sept. 30 to a charge of violating the Federal narcotic law. On Oct. 4 he was sentenced to a term of one year and one day and is to be placed on probation for two years, to commence at the end of the time to be served.

Memorial to Dr. Gerald Webb.—A Dr. Webb memorial committee has been formed in Colorado Springs to further the establishment in the new Glockner-Penrose Hospital of a memorial to the late Dr. Gerald B. Webb. Physicians serving on the committee include Harold H. Gile and John L. McDonald, Colorado Springs, John A. Sevier, Broadmoor, and James J. Waring, Denver, president of the Colorado Foundation for Research in Tuberculosis, which was founded by Dr. Webb in 1924. Plans for the memorial came as a spontaneous development in the current building fund drive to replace the present Glockner-Penrose Hospital, of which Dr. Webb was a staff member for more than 50 years, with a modern 300-bed structure, at a cost of about $5,400,000.

CONNECTICUT

Program on Neurologic Disorders.—Yale University School of Medicine will present a program, "Management of Chronic Neurologic Disorders," at 4 p. m., Dec. 7, in the Trask Room, Yale-New Haven Medical Center. Collaborators will be Drs. William J. German, professor of neurosurgery, Gilbert H. Glaser, assistant professor of neurology, and Thomas F. Hines, assistant professor of medicine.

Meeting on Cardiology.—On Dec. 14 at 8 p. m. "The Unequal Distribution of Red Cells and Plasma Within the Kidney: A Theory for Renal Hemodynamics" will be discussed by John R. Pappenheimer, Ph.D., professor of physiology, Harvard Medical School, Boston, under the sponsorship of the Cardiovascular Study Unit, Yale University School of Medicine, New Haven. The program, which is open without charge to all interested physicians, will be presented in the Fitkin Amphitheater.

Lectures on Medical Economics.—A series of lectures on economics of medical practice will be presented by the Connecticut State Medical Society and the department of public health, Yale University School of Medicine in the Brady Auditorium (310 Cedar St., New Haven) on Thursday at 4 p. m. The course, which comprises nine lecture and discussion classes, is open to medical students, graduate students, law students, interns and residents, and physicians. The first lecture (Dec. 2), "Medical Organization in the United States: Its Functions and Objectives" will be delivered by Dr. Ernest B. Howard, Assistant Secretary, American Medical Association, Chicago. On Dec. 15 "Entering Practice—Choosing a Location, Placement Services, State and Local Medical Societies, Professional Amenities, Announcements, Insurance" will be the subject of Dr. Creighton Barker, executive secretary, Connecticut State Medical Society.

ILLINOIS

Psychiatric Lecture.—Dr. Lewis L. Robbins, director, department of adult psychiatry, Menninger Foundation, Topeka, Kan., will present "Management of the Anxious Patient" Dec. 7, 8 p. m., at the North Shore Health Resort, 225 Sheridan Rd., Winnetka.

Dr. Proxmire Honored.—Dr. Theodore S. Proxmire, now in his 50th year of practice in Lake Forest, was recently honored at the annual Lake Forest day, which he originated in 1909. Dr. Proxmire's service to the community was the theme of floats in a parade that ended in West Park, where several hundred persons, at whose births he had officiated, participated in a program. The Lake Forest Woman's club presented him with $500, which he turned over to the Multiple Sclerosis Foundation.

Chicago

Dr. Rodbard Goes to Buffalo.—The University of Buffalo has announced the appointment of Dr. Simon Rodbard, assistant director of the Medical Research Institute at Michael Reese Hospital, as director and professor of experimental medicine of its Chronic Disease Research Institute.

Monthly Cardiac Conference.—The monthly clinicopathological cardiac conference of Cook County Hospital will be held Dec. 9 from 11 a. m. to 12 noon in the Children's Amphitheater, 700 S. Wood St. "The Present Status of Atherosclerosis" will be presented by Dr. Jeremiah Stamler, assistant director, cardiovascular department, Michael Reese Hospital.

Annual Institute Meeting.—The Institute of Medicine of Chicago, 86 E. Randolph St., will hold its 40th annual meeting Dec. 6 at the Furniture Club of America, 17th floor, 667 N. McClurg Ct. The annual reception and dinner for fellows of the institute, their wives, and other guests will precede the annual meeting at 8:30 p. m. The presidential address, "And the Valley Awakened," will be delivered at an open meeting, 9:30 p. m., by Dr. LeRoy H. Sloan. Telephone during the meeting: WHitehall 4-8552.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

First Lyon Award.—At the annual outing of the medical staff and alumni of St. Luke's Hospital, Dr. Paul H. Holinger, president of the medical staff, presented the first Dr. Will F. Lyon award to Dr. Gerald J. Kavanaugh, formerly of Fargo, N. D., now a fellow at the Mayo Foundation, Rochester, Minn. The award, sponsored by International Harvester Company in honor of Dr. Lyon, retired head of their medical department, is given annually to the St. Luke's intern who, ". . . in the performance of his duties, best exemplifies the high devotion and dedicated service which have characterized Dr. Lyon's professional career."

American Hospital Association.—At the ground-breaking ceremony, Nov. 9, for the proposed 17-story American Hospital Association headquarters and Center for Hospital Affairs at Pearson Street and Lake Shore Drive, Mayor Richard J. Daley said, "Chicago has often been described as the medical midpoint of the United States, and we think justly so—with so many fine national health organizations, medical teaching institutions and hospitals located here. We believe that the presence of the American Hospital Association headquarters and Center for Hospital Affairs will add to Chicago's already great luster as a health center." Other speakers included Dr. J. Roscoe Miller, president of Northwestern University, and Dr. Edwin L. Crosby, director of the American Hospital Association, who presided at the ceremonies. The new building, which will be constructed on a site made available to the association by Northwestern University, will cost about $4,850,000.

KANSAS

Medicolegal Seminar.—The Sedgwick County Medical Society will offer a seminar on legislative and medicolegal subjects, Jan. 6, 1956. Harvey T. Sethman, executive secretary, Colorado State Medical Society, will speak on national legislation affecting the practice of medicine. Mr. William Tinker, attorney for the Medical Protective Insurance Company, will speak on the increase in malpractice suits.

KENTUCKY

Survey on Rehabilitation Needs.—The newly appointed Governor's Committee on Rehabilitation will conduct a survey to encompass the resources and needs for training the physically and mentally handicapped in Kentucky. The survey will be under the supervision of the Legislative Research Commission. Physicians serving on the committee are J. Gant Gaither, Hopkinsville, president-elect, Kentucky State Medical Association; J. Murray Kinsman, Louisville, dean, University of Louisville School of Medicine; Franklin B. Moosnick and Marshal M. Jones, both of Lexington; and Asa Barnes, Louisville, who also serves as an alternate on the executive committee.

MARYLAND

Psychiatrist Goes to Ohio State.—Dr. Benjamin Pasamanick, formerly associate professor, division of mental hygiene, Johns Hopkins School of Hygiene, Baltimore, has been appointed professor of psychiatry at the Ohio State University College of Medicine, Columbus, and director of research at the Columbus State Psychiatric Institute. Dr. Pasamanick organized and administered residential and outpatient children's psychiatric services at the Michigan Neuropsychiatric Institute and the Kings County Hospital and has held teaching appointments at Yale University School of Medicine, New Haven, Conn.; University of Michigan Medical School, Ann Arbor; Long Island College of Medicine, Brooklyn, now State University of New York; and Johns Hopkins University School of Medicine, Baltimore. In 1949 he received the first Hofheimer Research prize awarded by the American Psychiatric Association.

MASSACHUSETTS

University News.—Tufts College, Medford, will hold its first academic convocation Dec. 8. The theme, "The Role of the Small University in American Higher Education," will be developed in symposiums at 10:30 a. m. in Cohen Auditorium. At 3 p. m. the academic convocation will be held in the Cousens Gymnasium. Guest speakers will be Arthur Sherwood Flemming, LL.D., Delaware, Ohio, and Roy Edward Larson, LL.D., L.H.D., New York City.

Course on Cardiology.—"The Heart and Great Vessels in 1955" is the subject of a course that will be presented Dec. 5-10 at the Massachusetts General Hospital, Boston, under the auspices of the American College of Physicians and the direction of Dr. Paul D. White. The fee for A. C. P. members is $30; for nonmembers, $60. Among others, the officers of instruction will include the following out-of-state physicians: E. Cowles Andrus and Helen B. Taussig, Baltimore; Charles P. Bailey, Philadelphia; Eugene Lepeschkin, Burlington, Vt.; Irvine H. Page, Cleveland; and Irving S. Wright, New York. There will be an appraisal of epidemiological and clinical follow-up studies, diagnostic techniques, and medical and surgical methods of treatment.

MICHIGAN

High Diabetes Mortality Rate.—The Michigan Department of Health reports that among the five leading causes of death in Michigan, diabetes is the only disease with a death rate that is higher than the rate for the country as a whole. Michigan's death rate in 1954 was 20.9 deaths per 100,000 population (1,469 diabetes deaths); the estimated rate for the nation was 15.4.

MINNESOTA

Personal.—Dr. Charles W. Mayo, Rochester, was recently elected a trustee of the University of Pennsylvania in Philadelphia. Dr. Mayo is an alumnus of the University of Pennsylvania School of Medicine.

Conference on Child Development.—The University of Minnesota, Minneapolis, announces a conference on the concept of development, in recognition of 30 years of research in child development at the university under the leadership of John E. Anderson, Ph.D., professor, Institute of Child Welfare. Meetings will be held in the Museum of Natural History Auditorium, Dec. 8-10. Physicians participating will include: John A. Anderson, head, department of pediatrics, University of Minnesota Medical School, Minneapolis (The Meaning of Growth and Development in the Practice of Pediatrics) and Hyman S. Lippman, director, Amherst H. Wilder Child Guidance Clinic, St. Paul (The Relation Between Early Childhood Development and Psychopathology). A dinner in honor of Dr. John E. Anderson will be held in the Junior Ballroom of the Coffman Memorial Union at 6:30 p. m., Dec. 8. Tickets, $3.50 each, may be secured from Dale B. Harris, Director, Institute of Child Welfare, University of Minnesota, Minneapolis 14.

NEW JERSEY

Personal.—Dr. Chester I. Ulmer, Gibbstown, was the guest of honor at a testimonial dinner sponsored by the Gibbstown Lions Club, Oct. 1, in recognition of his almost 40 years of professional service to the community. More than 400 citizens of Gibbstown and vicinity gathered in St. Michael's Hall to pay tribute to Dr. and Mrs. Ulmer.

Slide Seminar on Tumors.—The fifth annual slide seminar on "Unusual Tumors," sponsored by the New Jersey Society of Clinical Pathologists and the New Jersey State Department of Health (Bureau of Pathology) will be held Dec. 10 at 2 p. m. at the Nurses Auditorium, Presbyterian Hospital, Newark. The moderator will be Dr. Arthur Purdy Stout of Francis Delafield Hospital, Columbia University College of Physicians and Surgeons, New York.

Meeting of Chest Physicians.—The New Jersey chapter, American College of Chest Physicians, is presenting its fall scientific meeting Dec. 6, 8:45 p. m., at the Roosevelt Hospital for Chest Diseases in Metuchen. An x-ray conference dealing primarily with the residual sterile tuberculous cavity will have as panel discussants Drs. Oscar Auerbach, East Orange; Frank Bortone, Jersey City; Benjamin Copleman, Perth Amboy; Paul Geary, Plainfield; and Irving J. Selikoff, Paterson.

Martland Award.—The Essex County Pathological and Anatomical Society offers a prize of $250 under the annual Harrison S. Martland award for the best unpublished paper on pathology or anatomy or any of their phases. The essayist shall be known to the committee of judges by number only. Contestants are limited to all qualified hospital interns and residents in the state of New Jersey. Contributions must be in English, in manuscript form, in five copies, not exceeding 5,000 words, and mailed not later than Dec. 15, 1955, to Dr. Murray W. Shulman, Chairman, 913 S. 20th St., Newark 8.

Second Martland Lecture.—The annual Harrison S. Martland dinner, Dec. 14, 6:30 p. m., at the Essex House, 1050 Broad St., Newark, will precede the second Harrison S. Martland Memorial Lecture by Dr. Arthur M. Fishberg, director of medicine, Beth Israel Hospital, New York City, at the Academy of Medicine of New Jersey, 91 Lincoln Park South, Newark. Dr. Fishberg will have as his subject "The Cerebral Phenomena of Hypertension and Their Treatment." All members of the medical profession and their guests are invited to the dinner ($5 per person; dress optional) and the lecture. No reservations for the dinner will be accepted after Dec. 5. Mail checks to Dr. Royal A. Schaaf, Treasurer, 413 Mt. Prospect Ave., Newark.

NEW YORK

University News.—Albany Medical College of Union University announces the following promotions in its department of pediatrics: Dr. Edward S. Goodwin to clinical professor of pediatrics; Dr. Edward R. Schlesinger to assistant clinical professor of pediatrics; and Drs. Thomas F. Riedy Jr., Allan MacCollam, and John W. Abbuhl to instructor in pediatrics.

Report on Fluorine Study.—The New York Institute of Clinical Oral Pathology announces an open meeting to which members of the medical, dental, and allied professions are invited. The final report on the Newburgh-Kingston Caries Fluorine Study (Dec. 12, 8:30 p. m., at the New York Academy of Medicine Building, 2 E. 103rd St.) will include:

History of the Newburgh-Kingston Caries-Fluorine Study, Herman E. Hilleboe, Albany.
Pediatric Aspects, Edward R. Schlesinger, Albany.
Fluoride Metabolism, Harold C. Hodge, Ph.D., Rochester.
Dental Aspects, David B. Ast, D.D.S., Albany.

Named to Joint Post.—Dr. Jacob David Goldstein, associate professor in medicine and in bacteriology, University of Rochester School of Medicine and Dentistry, has been named to the joint post of professor of medicine at the State University of New York College of Medicine at New York City in Brooklyn and chief of medicine at the Jewish Hospital of Brooklyn. Dr. Goldstein served as director of laboratories at Genesee Hospital in Rochester from 1947 to 1951. During World War II he was a colonel in the Army Medical Corps, serving as chief of laboratory services for the 19th General Hospital in England and France.

New York City

Hauswirth Lecture.—The seventh annual Louis Hauswirth Lecture in Medicine, sponsored by the Beth David Hospital Alumni Association, will be delivered by Dr. Sidney C. Werner, associate professor of clinical medicine, chief of combined endocrine clinic, and associate attending physician, Presbyterian Hospital, Dec. 8, at 8:30 p. m. The lecture, "Selection of Therapy in Thyroid Diseases," will be held at Beth David Hospital, 161 E. 90th St.

Meeting on Preoperative Care.—The New York chapter of the International Academy of Proctology invites members of the medical profession to a meeting on the preoperative management of colonic surgery at 8:30 p. m., Dec. 6, at the Hotel Plaza (Fifth Avenue and 59th Street). The following papers will be presented:

Cardiorenal and Metabolic Factors, Paul H. Kuhn.
Fluid, Electrolyte, and Blood Constituent Balance, Kurt Lange.
Use of Antibiotics in Colonic Surgery, Russell F. Cahoon, Pearl River, N. Y.

Schoenberg Memorial Lecture.—The Mark J. Schoenberg Memorial Lecture, sponsored jointly by the National Society for the Prevention of Blindness and the New York Society for Clinical Ophthalmology, will be given Dec. 5, 8:15 p. m., at the New York Academy of Medicine. Dr. Irving H. Leopold, chairman, department of ophthalmology, Graduate School of Medicine, University of Pennsylvania, Philadelphia, will present "Advances in the Medical Treatment of Glaucoma." All physicians will be welcome.

Medical Lectures for the Public.—The New York Academy of Medicine, 2 E. 103rd St., is presenting as its 21st series of Lectures to the Laity "Medicine and Anthropology," with the support of the Wenner-Gren Foundation for Anthropological Research. The first lecture in the series, the Linsly R. Williams Memorial Lecture, "Man, Magic and Medicine," was delivered by Dr. Paul Fejos, president of the foundation, on Nov. 23. On Dec. 7 at 8:30 p. m. "The Ecology of Health" will be considered by Marston Bates, Ph.D., professor of zoology, University of Michigan, Ann Arbor.

Personal.—Dr. Leon Roizin has been appointed principal research scientist, neuropathology, at the New York State Psychiatric Institute to succeed Dr. Armando Ferraro, who retired last year.——Dr. I. Herbert Scheinberg has resigned as principal research scientist, internal medicine, at the New York State Psychiatric Institute to become associate professor of medicine at the Albert Einstein College of Medicine. Dr. Bernard C. Holland has been appointed to succeed Dr. Scheinberg at the institute.——Dr. Douglas Quick recently delivered the Herman L. Reiss Memorial Lecture on "Contributions of Radiation in the Treatment of Malignant Tumors of the Jaws," before the New York Institute of Clinical Oral Pathology.

Diarrheal Diseases of Infants.—A conference on diarrheal diseases of the infant will be presented Dec. 8-9 at the Barbizon-Plaza Hotel (101 W. 58th St., at 6th Avenue) under the sponsorship of the section of biology, New York Academy of Sciences (2 E. 63rd St.). Presentations by out-of-state speakers include:

Diarrheal Diseases of Man: A Historical Review and Global Appraisal, Albert V. Hardy, Jacksonville, Fla.
Host-Microbe Relationships, Walter J. Nungester, Ann Arbor, Mich.
Active and Passive Immunity of the Infant, Geoffrey Edsall, Washington, D. C.
Salmonellae and Salmonellosis, Philip R. Edwards, Ph.D., Chamblee, Ga.
An Epidemic of Salmonella Panama Infection in Infants, Frederick S. Leeder, Lansing, Mich.
Enteropathogenic Escherichia Coli, William H. Ewing Ph.D., Chamblee, Ga.
Infantile Diarrhea Due to Escherichia Coli, Cyril S. Stulberg and Wolf W. Zuelzer, Detroit.
Studies on Enteropathogenic Escherichia Coli, Col. Robert B. Lindberg, Ph.D., Washington, D. C.
Epidemiologic Studies of Enteropathogenic Escherichia Coli Diarrhea, Aaron H. Stock, Pittsburgh.
Spread and Control of Escherichia Coli Diarrheal Disease, Warren E. Wheeler, Columbus, Ohio.
Epidemic Diarrheal Disease of Suckling Mice, Francis S. Cheever, Pittsburgh.
Significance of Viruses Recovered from the Intestinal Tract of Healthy Infants and Children, Albert B. Sabin, Cincinnati.

OHIO

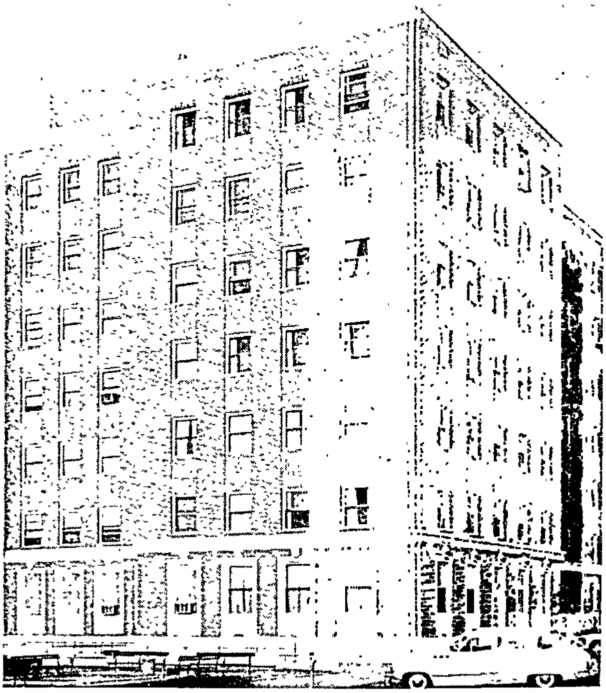
Society News.—The Academy of Medicine of Cincinnati (152 E. Fourth St.) will present "Some Recent Advances in Clinical Endocrinology" by Dr. E. Perry McCullagh, Cleveland, Dec. 6. ——Officers of the Cincinnati Otolaryngological Society include: Dr. Ervin S. Ross, president, and Dr. Joseph A. Lane, treasurer.

Memorial Postgraduate Day.—On Oct. 12 the active medical staff of Manfield General Hospital sponsored the first of a proposed annual "Dr. Harro Woltmann Postgraduate Day" as a memorial honoring Dr. Woltmann, a former staff member. The speakers were Dr. Harold J. Jeghers, Washington, D. C., and Drs. Harry Goldblatt, Stanley O. Hoerr, and Oscar D. Ratnoff, Cleveland.

TENNESSEE

Personal.—A portrait of Dr. R. Eustace Semmes, professor of neurological surgery, University of Tennessee College of Medicine, Memphis, was presented to the university by his former residents at the Baptist Memorial and John Gaston hospitals in Memphis. Presentation was made by Dr. Francis Murphey, Memphis, at a luncheon honoring Dr. Semmes.

Medical-Surgical Building.—The recently completed $731,033 Medical-Surgical Building of the University of Tennessee College of Medicine, Memphis, adds 40,000 square feet of floor space to Memphis' medical center. The first four floors of the seven-floor building, which connect with Gailor Memorial Psychiatric Hospital by corridors, will serve as the outpatient department of John Gaston Hospital. On the fifth floor will be a radioactive isotope clinic for study and treatment of selected diseases, an orthopedic clinic and cast room, and dermatology and hematology clinics. The sixth and seventh floors will be occupied by the west Tennessee laboratory of the state health department.



Medical-Surgical Building in Memphis.

VIRGINIA

Stuart McGuire Lecture.—Dr. Richard W. TeLinde, professor of gynecology, Johns Hopkins University School of Medicine, Baltimore, will deliver the annual Stuart McGuire Lecture on endometriosis at the Medical College of Virginia, Richmond, Dec. 7. He will also participate in the symposium Dec. 8-9, with Drs. John L. Parks, Robert H. Barter, and Andrew A. Marchetti, Washington, D. C.; Drs. F. Bayard Carter and Roy T. Parker, Durham, N. C.; Dr. Houston S. Everett, Baltimore; Dr. Frank R. Lock, Winston-Salem, N. C.; Drs. William N. Thornton Jr. and John M. Nokes, Charlottesville; and Erling S. Hegre, Ph.D., Richmond. All lectures will be in the Baruch Auditorium of the Egyptian Building at the college. There is no charge for the McGuire Lecture, but there will be a charge of $5 a day for the symposium lectures, except to members of the faculty of the college, the University of Virginia School of Medicine, Charlottesville, physicians of the McGuire Veterans Administration Hospital, medical students, and members of the house staff of any hospital.

WISCONSIN

Course in Cardiology.—The University of Wisconsin Medical School, Madison, offers a graduate course in cardiology Dec. 6-8. A panel discussion will conclude the Tuesday sessions. Ward rounds are scheduled for Wednesday and Thursday, 8 a. m. The sessions will end Thursday afternoon after a symposium on hypertension. Registration fee is $5; course fee, $15. Applications should be sent to Dr. Robert C. Parkin, University of Wisconsin Medical School, 418 N. Randall Ave., Madison 6.

Symposium on Metabolism.—The University of Wisconsin Medical School, Madison, presented a symposium, "Metabolic Aspects of Transport Across Cell Membranes," Aug. 29-31, with the cooperation of the Wisconsin Alumni Research Foundation and the National Science Foundation. Dr. F. E. Shideman, professor of pharmacology and toxicology, presided at a round-table discussion on "Transport of Organic Compounds Across Renal Epithelium." Dr. Q. R. Murphy, associate professor of physiology, was chairman of the committee in charge of arrangements for the symposium.

Program on Physical Diagnosis.—A postgraduate course on physical diagnosis is offered by Marquette University, Milwaukee, on Wednesdays, Dec. 7-Jan. 18, from 10 a. m. to noon. Cardiology I, Cardiology II, and Abdomen will be the subjects at Milwaukee County Hospital Dec. 7, 14, and 21 respectively. Musculoskeletal Diseases, Chest, and Neurology will be considered at the Veterans Administration Hospital, Wood, Jan. 4, 11, and 18, 1956, respectively. Dr. Joseph W. Rastetter, associate professor of medicine and assistant director of the department of medicine, will be the director of the course. Registration is limited to 30 persons. The Wisconsin Academy of General Practice is allotting 12 credits.

PUERTO RICO

Annual Medical Meeting in Santurce.—The 52nd annual assembly of the Puerto Rico Medical Association will convene in Santurce Dec. 6-10 under the presidency of Dr. Ricardo F. Fernández, Santurce. Dr. Elmer Hess, Erie, Pa., President of the American Medical Association, will deliver an address at the opening meeting Tuesday, 8 p. m., at the Hotel Caribe Hilton. He will also speak Wednesday, 9:30 p. m., at the association headquarters, Avenida Fernandez Juncos-Parada 19, his topic being "The General Practitioner as an Urologist." The other guests of honor and their first presentations include:

Jerome W. Conn, Ann Arbor, Mich., Clinical Implications of Aldosterone, the Newly Recognized Adrenal Steroid.
Bernard J. Alpers, Philadelphia, The Problems of Cerebral Aneurysm.
William F. Finn, New York City, Induction and Stimulation of Labor.
John H. Garlock, New York City, Surgical Treatment of Cancer of the Esophagus and Cardia with an Appraisal of Long Term Results.
Arnold R. Rich, Baltimore, Studies on the Pathogenesis of Cirrhosis of the Liver.
Rufus H. Alldredge, New Orleans, Cineplastic Method for Upper Extremity Amputation (illustrated by motion picture).

A symposium on anemias in Puerto Rico is scheduled at the school of medicine at 2:30 p. m. Wednesday. Thursday morning will be devoted to the Capital Hospitals. The session will begin with ward rounds in all services at 8:30 a. m. and conclude at 11 a. m. with a clinical pathological conference. A similar morning will be spent Friday at the Hospital San Patricio. The session at the association headquarters Friday afternoon will open with a symposium on breast cancer. The presidential reception is scheduled for Tuesday night, after the address by Dr. Hess, and the annual banquet for Saturday at the Caparra Country Club.

GENERAL

Meeting on Rheumatism.—The second interim scientific session of the American Rheumatism Association will convene Dec. 9 at the Clinical Center, National Institutes of Health, Bethesda, Md. Eighteen papers will be presented. A tour of the laboratories is scheduled for Friday afternoon. Dr. Charles L. Short, Boston, is president of the association.

Meeting on Epilepsy.—The American League Against Epilepsy will hold its annual meeting Dec. 8 at the Roosevelt Hotel, New York City. The morning session will be devoted to a symposium on advances in medical therapy, for which Dr. William G. Lennox, Boston, will serve as chairman, and at 9 a. m. will deliver opening remarks on the WHO Conference on Epilepsy. The afternoon session will open with the presidential address by Dr. Russell N. DeJong, Ann Arbor, Mich. In all, 17 presentations have been scheduled.

Semmelweis Lecture.—At the annual Semmelweis meeting of the American-Hungarian Medical Association Dec. 9 at the Hosack Hall of the New York Academy of Medicine, Dr. Hans Selye, director of the Institute for Experimental Medicine and

Surgery, Montreal, Canada, will deliver the Semmelweis Lecture, "Recent Progress in the Study of Stress." Dr. Selye will be presented with the Ignatz Semmelweis medal, awarded annually by the American-Hungarian Medical Association to an outstanding scientist of Hungarian origin. Preceding the meeting he will be feted at a dinner in the Presidents Gallery of the New York Academy of Medicine.

Teaching Legal Medicine in Law Schools.—The Association of American Law Schools will hold a meeting at the Conrad Hilton Hotel, Chicago, Dec. 28-30, at which there will be a round-table council on law and psychology to discuss the teaching of legal medicine in the law schools of the United States. Dr. Robert N. Hamlin is scheduled to present the program in legal medicine as it is taught at Harvard Law School, Cambridge, Mass., and Professor L. Whiting Farinholt Jr., of the University of Maryland, Baltimore, Professor Polsky of Temple University, Philadelphia, and Mr. Oliver Schroeder Jr. of Western Reserve University, Cleveland, will discuss the programs in their respective schools.

Lalor Foundation Awards.—The Lalor Foundation will offer 40 awards in its 1956 series of summer awards for research in the biological sciences. These awards, available to members of college and university faculties (age limit, 40 years), are for advanced study and research employing chemistry or physics to attack problems in any field of biology. The awards will usually not exceed $900 for a single man or woman, $1,100 for a married person working at his home institution, and $1,200 for a married person whose principal program is at another institution. Inquiries should be addressed to the Director of the Lalor Foundation, 4400 Lancaster Pike, Wilmington 5, Del. Final date for receipt of completed applications is Jan. 14, 1956.

Radiologists Meet in Chicago.—The Radiological Society of North America will hold its 41st annual meeting at the Palmer House, Chicago, Dec. 12-16. The presidential address by Dr. Thomas B. Bond, Fort Worth, Texas, will precede "College Report on Present Status of Blue Cross and Blue Shield" by Dr. Warren W. Furey, Chicago, and "Radiation Control Legislation" by Lauriston S. Taylor, A.B., Washington, D. C. Panels are scheduled on hemoptysis (Dr. Raymond R. Lanier, Chicago, moderator), curative treatment of cancer of the breast (Dr. Donald S. Childs Jr., Rochester, Minn., moderator), and the acute abdomen (Dr. Philip J. Hodes, Philadelphia, moderator). Dr. James W. J. Carpender, Chicago, will serve as moderator for a symposium on supervoltage. The annual banquet is scheduled for 8 p. m. Thursday.

Annual Meeting on Nervous and Mental Disease.—The Association for Research in Nervous and Mental Disease will hold its 35th annual meeting at the Hotel Roosevelt, New York City, Dec. 9-10. The subject, "The Neurologic and Psychiatric Aspects of the Disorders of Aging," will be developed in 14 presentations preceding the Saturday afternoon panel discussion, "The Physician's Contribution to the Role of Older Persons in Society" (chairman, Dr. D. Ewen Cameron, Montreal, Canada), which will include:

Acute Breakdowns, Eugene Meyer, Baltimore.
Retirement, James S. Tyhurst, Montreal, Canada.
Retirement, with Special Emphasis on Retirement Plans, Mr. D. S. Sargent, New York.
General Advice by the Physician, David Seegal, New York.
Effects of Cultural Anticipations and Attitudes Toward Aging, Margaret Mead, Ph.D., New York.
Psychotherapy of the Aged Person, Jack Weinberg, Chicago.
Rehabilitation of the Aged, Frederic D. Zeman, New York.

Muscular Dystrophy Projects.—Muscular Dystrophy Associations of America, Inc., 39 Broadway, New York 6, N. Y., recently allocated $175,642 for continuation of 13 research projects and for 6 new scientific projects. The association, with its more than 200 chapters throughout the country, issued a call for 500,000 volunteers to join the 1955 March for Muscular Dystrophy during Thanksgiving Week to raise funds for continued research, patient care, and a constantly expanding network of clinics nationwide. The association's program of research includes construction of a muscle research center in New York City, adjacent to and allied with New York Hospital-Cornell Medical Center. Two million dollars has been earmarked for the start of the project, which will be specially staffed and equipped, with provision for 50 laboratories, and will serve as a clearing house for research information.

Pharmaceutical Manufacturers' Award Dinner.—The American Pharmaceutical Manufacturers' Association has scheduled its annual award dinner at the Waldorf-Astoria, New York City, Dec. 13, in connection with its combined midyear and eastern section meeting, Dec. 12-14. The association's 17th annual award will be bestowed on Dr. Charles W. Mayo, Rochester, Minn., for "providing a new therapeutic formula to aid international understanding in a politically sick world." Dr. Mayo first took an active role in world political affairs in 1953 as a member of the U. S. delegation to the General Assembly of the United Nations. The following year he was elected president of the American Association for the United Nations. At the scientific sessions Dr. Morris Fishbein, Chicago, will speak on uniform procedures for product registration and labeling in Latin America. His presentation will include information on the recent conference of the Pan American Medical Confederation in Bogota, Colombia. During the medical and scientific session Tuesday afternoon, drug therapy in mental disease will be discussed by Dr. Baldwin L. Keyes, Philadelphia, Dr. Francis J. O'Neill, Central Islip, N. Y., and Dr. Howard D. Fabing, Cincinnati. The meetings will end with a luncheon at 12:30 p. m. Wednesday. The registration fee ($15) includes a ticket for the luncheon; extra tickets are available at $7.50.

Society News.—Dr. Howard A. Rusk, president, **International Society for the Welfare of Cripples,** announces the appointment of Hendrik Nieuwenhuize, M.A., of Amsterdam, The Netherlands, to the staff of the society. Before coming to New York, Mr. Nieuwenhuize served as secretary-general of the Netherlands National Federation for Mental Health.——The **National Multiple Sclerosis Society** has appointed as scientific director Frederick L. Stone, Ph.D., assistant for professional services to the vice-chancellor, School of the Health Professions, University of Pittsburgh. Dr. Stone's responsibility will be to develop research and medical programs and to administer all research grants and fellowships.——Newly elected officers of the **Academy of Psychosomatic Medicine** include: Dr. Alfred J. Cantor, Flushing, N. Y., president; Dr. Samuel M. Poindexter, Boise, Idaho, president-elect; Dr. Harry Phillips, East St. Louis, Ill., first vice-president; Dr. Carlos Seguin, Lima, Peru, second vice-president; Dr. Ethan Allan Brown, Boston, secretary; and Dr. George F. Sutherland, Baltimore, treasurer.——Newly elected officers of the **American Roentgen Ray Society** include: Dr. Paul C. Hodges, Chicago, president; Dr. W. Edward Chamberlain, Philadelphia, president-elect; Dr. Milo T. Harris, Spokane, Wash., first vice-president; Dr. John P. Medelman, White Bear Lake, Minn., second vice-president; Dr. Barton R. Young, Philadelphia, secretary; and Dr. Wendell G. Scott, Clayton, Mo., treasurer.

Resident Exchange Program and the Horse Shoe Club.—The American College of Surgeons announces a program of exchange of surgical residents between this country and Great Britain, under the sponsorship of the Horse Shoe Club. Arrangements for the exchange will be accomplished by the graduate training committee of the American College of Surgeons in this country. The original plans call for an exchange of about one year's duration, the American resident usually being at the second or third year level. Those coming from Great Britain may be somewhat further along in their training programs but will be fitted into the American residency so as to provide the best opportunity for training and experience. The host institution is expected to provide for the living expenses of the visiting students, but the travel expense is to be borne by the parent hospital. The Horse Shoe Club, composed of British, Canadian, and American members, was founded in 1932 to foster friendship and the exchange of medical, research, and clinical workers between the three countries. In Great Britain, the club offers hospitality to visitors from the United States and Canada and assists in making arrangements for visits to British hospitals. This exchange program does not interfere in any way with exchange programs that now exist or that may be established. Private arrangements made between schools and hospitals in both countries are all important, and it is hoped that they will be amplified. Those responsible for approved programs of training in general surgery and the surgical specialties in this country are invited to participate in the exchange program. Inquiries should be addressed to the American College of Surgeons, 40 E. Erie St., Chicago 11.

Meeting on Medical Education and Industry.—A conference on the education of physicians for industry will be held at the Mellon Institute, Pittsburgh, Dec. 6-8 under the sponsorship of the National Fund for Medical Education, the Association of American Medical Colleges, and the A. M. A. Council on Industrial Health and Council on Medical Education and Hospitals. Dr. Robert A. Kehoe, Cincinnati, conference chairman, will preside at the opening session Tuesday morning, at which the address of welcome by Dr. Edward R. Weidlein, Pittsburgh, president of the institute, will be followed by a seminar, "Responsibilities of Society for Health in Our Industrial World." Dr. Norvin C. Kiefer, New York City, chief medical director, Equitable Life Assurance Society of the United States, will outline "Needs and Problems." The problems of industrial health will be considered by Mr. William Seymour, senior vice-president, *Liberty Mutual Insurance Company, for the industrialist;* Dr. Leo Wade, New York City, medical director, Esso Standard Oil Company, for the medical administrator; and Clinton S. Golden, LL.D., Boston, former executive director, Trade Union Program, Graduate School of Business Administration, Harvard University, for the industrial worker. The seminar will be followed by panel sessions. Dr. Ward Darley, Denver, president, University of Colorado, will address the dinner meeting at 6:45 p. m., his subject being "The Widening Horizons of Medical Education." Panel sessions will be continued Wednesday. Thursday morning Dr. Vernon W. Lippard, New Haven, Conn., president, Association of American Medical Colleges, will give the summation and comment. Thursday afternoon will be devoted to a symposium on medical education and industry, with Mr. S. Sloan Colt, New York City, president, National Fund for Medical Education, presiding. The address of welcome by General Matthew B. Ridgeway, Washington, D. C., chairman, Mellon Institute, will precede the symposium:

Robert A. Moore, Pittsburgh, Medicine Tomorrow.
Mr. Harry W. Anderson, Medicine and Manpower.
Mr. M. J. Rathbone, Our Debt to Medical Science.
Mr. Clifford F. Hood, Industry's Stake in Rising Health Standards.

LATIN AMERICA

Congress of Pathologic Anatomy.—The first Latin-American Congress of Pathologic Anatomy will be held in Mexico City, Dec. 11-17, under the auspices of the president of Mexico, the secretariat of public health, and the Mexican Association of Pathologists, with the collaboration of the UNESCO Center of Scientific Cooperation for Latin America. Dr. Isaac Costero will be the president of the congress. Spanish, Portuguese, and English will be the official languages for official topics, lectures, and round-table discussions. The registration fee is about $16. Information can be obtained from: Instituto Nacional de Cardiologia, Avenida Cuahtemoc 300, Mexico, 7, D. F., Mexico.

DEATHS IN OTHER COUNTRIES

Dr. med. Karl Haedenkamp, who had long been active in the Association of German Physicians, died July 13 in Garmisch-Partenkirchen, Germany, after a brief illness. Dr. Haedenkamp had been awarded medals by the government of the West German Republic and the Paracelsus medal of the Society of German Physicians.

Dr. Ghulam Muhammad Khan Baloch, M.D. (Pb.) M.R.C.P. (London), professor of medicine in Fatima Jinnah Medical College, Lahore, West Pakistan, died April 23 after a prolonged illness. Dr. Baloch, a graduate of the University of the Punjab, was previously affiliated with the Department of Medicine, King Edward Medical College, Lahore. He was treasurer of the Pakistan Association for the Advancement of Science and of the Pakistan Science Conference 1953 (Medical Section), and served as secretary of the Pakistan Medical Association, Punjab Branch.

CORRECTION

American Diabetes Association.—In the Medical News, page 1131 of the Nov. 12, 1955, issue of The Journal, Dr. Henry Ricketts was referred to as "former president of the American Diabetes Association." Dr. Ricketts is currently president of the association.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1956 Annual Meeting, Chicago, June 11-15.
1956 Clinical Meeting, Seattle, Nov. 27-30.
1957 Annual Meeting, New York, June 3-7.
1957 Clinical Meeting, Philadelphia, Dec. 3-6.

Annual Congress on Industrial Health, Sheraton-Cadillac Hotel, Detroit, Jan. 25-24. Mr. Clark D. Bridges, 535 N. Dearborn St., Chicago 10, Acting Secretary.

American Academy of Dermatology and Syphilology, Palmer House, Chicago, Dec. 3-8. Dr. James R. Webster, 55 East Washington St., Chicago 2, Secretary.

American Academy of Obstetrics and Gynecology, Conrad Hilton Hotel, Chicago, Dec. 13. Dr. C. Paul Hodgkinson, 116 South Michigan Blvd., Chicago, Secretary.

American League Against Epilepsy, Roosevelt Hotel, New York, Dec. 8. Dr. Peter Kellaway, Baylor University College of Medicine, Houston 25, Tex., Secretary.

American Rheumatism Association, Interim Session, National Institutes of Health, Bethesda, Md., Dec. 9. Dr. Edward F. Hartung, 580 Park Ave., New York 21, Secretary.

Association for Research in Nervous and Mental Diseases, Hotel Roosevelt, New York, Dec. 9-10. Dr. Clarence C. Hare, 710 West 168th St., New York 32, Secretary.

Eastern Section, American Laryngological, Rhinological and Otological Society, Boston, Jan. 13. Dr. John A. Murtagh, Dartmouth College, Hanover, N. H., Vice President.

Los Angeles Midwinter Medical Convention, Biltmore Hotel, Los Angeles, Jan. 3-5. Dr. Paul D. Foster, 1925 Wilshire Blvd., Los Angeles 58, General Chairman.

Middle Section, American Laryngological, Rhinological and Otological Society, Netherland Plaza, Cincinnati, Jan. 16. Dr. William H. Craddock, 2328 Auburn Ave., Cincinnati 19, Vice President.

Puerto Rico Medical Association, Santurce, Dec. 7-11. Dr. Luis R. Guzman-Lopez, Box 9111, Santurce, Secretary.

Radiological Society of North America, Palmer House, Chicago, Dec. 11-16. Dr. Donald S. Childs. 713 E. Genesee St., Syracuse 2, N. Y., Secretary.

Regional Meetings, American College of Physicians:

Winston-Salem, N. C., Dec. 8. Dr. Elbert Persons, Duke Hospital, Durham, N. C., Governor.

Shreveport, La., Jan. 14, Dr. M. D. Hargrove, 803 Jordan St., Shreveport, La., Governor.

Philadelphia, Jan. 20. Dr. Thomas M. McMillan, 330 South 9th St., Philadelphia 7, Governor.

Sectional Meetings, American College of Surgeons:

Jacksonville, Fla., Hotel George Washington, Jan. 16-18. Dr. Kenneth A. Morris, 2522 Oak St., Jacksonville 4, Fla., Chairman.

Southern Section, American Federation for Clinical Research, Jung Hotel, New Orleans, Jan. 20. Dr. John H. Moyer, 1200 M.D. Anderson Blvd., Houston, Tex., Secretary.

Southern Section, American Laryngological, Rhinological and Otological Society, The Shamrock, Houston, Texas, Jan. 27-28. Dr. J. M. Robison, 1304 Walker Ave., Houston 2, Texas, Chairman.

Southern Surgical Association, The Homestead, Hot Springs, Va., Dec. 6-8. Dr. George G. Finney, 2947 St. Paul St., Baltimore 18, Secretary.

Southern Thoracic Surgical Association, The Greenbrier, White Sulphur Springs, W. Va., Dec. 2-5. Dr. Hawley H. Seiler, 442 West Lafayette St., Tampa 6, Fla.

Western Section, American Federation for Clinical Research, La Playa Hotel and Golden Bough Theater, Carmel, Calif., Jan. 25. Dr. B. H. Scribner, Veterans Administration Hospital, Seattle 8, Washington, Secretary.

Western Section, American Laryngological, Rhinological and Otological Society, County Medical Society Bldg., San Francisco, Jan. 21. Dr. David D. DeWeese, 1216 S. W. Yamhill St., Portland, Ore., Vice President.

FOREIGN AND INTERNATIONAL

All India Medical Conference, Jaipur, India, Dec. 26-28. Dr. B. N. Consul, Association Bldg., S.M.S. Hospital Premises, Jaipur, India, Organizing Secretary.

Canadian Medical Association, Quebec, P. Q., Canada, June 10-14, 1956. Dr. Arthur D. Kelly, 150 St. George St., Toronto 5, Ont., Canada, Secretary.

Conference of International Union for Health Education of the Public, Rome, Italy, Apr. 27-May 5, 1956. Mr. Lucien Viborel, 92 rue St. Denis, Paris 1^{er}, France, Secretary-General.

Congress of International Anesthesia Research Society, Miami Beach, Fla., U.S.A., April 9-12, 1956. *For information write:* Dr. R. J. Whitacre, 13951 Terrace Road, Cleveland 12, Ohio, U. S. A.

Congress of International Association of Limnology, Helsinki, Finland, July 26-Aug. 7, 1956. For information address: Dr. H. Luther, Snellmansgatan 16 C 36, Helsinki, Finland.

Congress of International Association of Logopedics and Phoniatrics, Barcelona, Spain, Sept. 3-7, 1956. Dr. J. Perello, Provenza 319, Barcelona 9, Spain, Secretary-General.

Congress of International Society of Hematology, Hotel Somerset, Boston, Mass., U.S.A., Aug. 27-Sept. 1, 1956. Dr. W. C. Moloney, 39 Bay State Road, Boston, Mass., U.S.A., Secretary.

Congress of Latin Society of Ophthalmology, Madrid, Spain, April 24-28, 1956. For information address: Dr. Costi, Montalban 3, Madrid, Spain.

European Congress of Allergology, Florence, Italy, Sept. 12-15, 1956. Prof. Umberto Serafini, Instituto de Patologia Medica, Viale Morgagni, Florence, Italy, Secretary-General.

European Congress of Cardiology, Stockholm, Sweden, Sept. 10-14, 1956. Dr. Karl Erik Grewin, Sodersjukhuset, Stockholm, Sweden, General Secretary.

European Symposium on Vitamin B_{12}, Hamburg, Germany, May 1956. For information write: Doz. Dr. H. Bauer, Nervenklinik. Hamburg-Eppendorf, Germany.

Inter-American Congress of Cardiology, Havana, Cuba, Nov. 4-10, 1956. For information address: Dr. Ramon Aixala, Apartado 2108, Havana, Cuba.

International Academy of Pathology, Cincinnati, Ohio, U. S. A., April 24-25, 1956. Dr. F. K. Mostofi, Armed Forces Institute of Pathology, Washington 25, D. C., U. S. A., Secretary.

International Congress Against Alcoholism, Istanbul, Turkey, Sept. 10-15, 1956. For information address: International contre l'Alcoolisme, Case Gare 49, Lausanne, *Switzerland.*

International Congress of Anthropological and Ethnological Sciences, Philadelphia, Pa., U. S. A., Sept. 2-9, 1956. Dr. William N. Fenton, National Research Council, Division of Anthropology and Psychology, 2101 Constitution Avenue, Washington 25, D. C., U. S. A., Secretary-General.

International Congress of Blood Transfusion, Boston, Mass., U. S. A., Aug. 29-Sept. 2, 1956. Dr. J. Julliard, 57, Boulevard L'Auteuil, Boulonge-sur-Seine, France, Secretary General.

International Congress on Diseases of the Chest, Cologne, Germany, Aug. 19-23, 1956. Mr. Murray Kornfeld, 112 East Chestnut St., Chicago 11, Illinois, U. S. A., Executive Director.

International Congress of Entomology, Montreal, Canada, Aug. 17-25, 1956. Mr. J. A. Downes, Science Service Bldg., Carling Ave., Ottawa, Ont., Canada, Secretary.

International Congress of Gastroenterology, London, England, July 18-21, 1956. Mr. Hermon Taylor, London Hospital, White Chapel, London E.1, England, Honorable Secretary.

International Congress for the History of Science, Florence and Milan, Italy, Sept. 3-10, 1956. Dr. M. L. Bonelli, Instituto di Ottica, Arcetri, Florence, Italy, Secretary-General.

International Congress of Human Genetics, Copenhagen, Denmark, Aug. 1-6, 1956. For information address: The University Institute for Human Genetics, Tagensvej 14, Copenhagen N, Denmark.

International Congress of Hydatid Disease, Athens, Greece, Sept. 14-18, 1956. Prof. B. Kourias, Croix-Rouge Hellenique, 1 rue Mackenzie King, Athens, Greece, Secretary-General.

International Congress of Internal Medicine, Madrid, Spain, Sept. 19-23, 1956. Dr. J. C. De Oya and Dr. J. Gimena, Hostaleza No. 90, Madrid, Spain, Secretaries.

International Congress of International College of Surgeons, Palmer House, Chicago, Illinois, U. S. A., Sept. 9-13, 1956. Dr. Max Thorek, 1516 Lake Shore Drive, Chicago, Illinois, U. S. A., Secretary-General.

International Congress of Neo-Hippocratic Medicine, Montecatini, Terme, Italy, May 20-22, 1956. Dr. Valente, 41 Avenue Verdi, Montecatini Terme, Italy, Secretary-General.

International Congress of Paediatrics, Copenhagen, Denmark, July 22-27, 1956. Professor P. Plum, Rigshospitalet, Copenhagen, Denmark, President.

International Congress of Physical Medicine, Copenhagen, Denmark, August 20-24, 1956. Dr. B. Strandberg, Kobenhavns amts sygehus i Gentofte, Dept. of Rheumatology and Physical Medicine, Hellerup, Denmark, Honorable Secretary.

International Congress of Physiopathology of Animal Reproduction and Artificial Insemination, Cambridge, England, June 25-29, 1956. For information address: Dr. Joseph Edwards, Production Division, Milk Marketing Board, Thames Ditton, Surrey, England.

International Congress of Radiology, Mexico, D. F., Mexico, July 22-28, 1956. Dr. Jose Noriega, Tepic 126 (2e piso), Mexico, D. F. 7, Mexico, Secretary General.

International Congress of World Confederation for Physical Therapy, Hotel Statler, New York, New York, U. S. A., June 17-23, 1956. For information address: Miss Mildred Elson, American Physical Therapy Association, 1790 Broadway, New York 19, New York, U. S. A.

International Genetics Symposium, Tokyo and Kyoto, Japan, Sept. 6-12, 1956. For information address: Secretary, International Genetics Symposium, Science Council of Japan, Ueno Park, Tokyo, Japan.

International Physiological Congress, Brussels, Belgium, July 29-Aug. 5, 1956. For information address: Prof. J. Reuse, Faculte de Medicine et de Pharmacie, 115 Boulevard de Waterloo, Brussels, Belgium.

International Professional Union of Gynecologists and Obstetricians, Madrid, Spain, Sept. 28-29, 1956. Dr. Jacques Courtois, 1 rue Racine, St-Germain-en-Laye (S and O), France, Permanent International Secretary-General.

Latin American Congress of Pathology, Mexico, D. F., Mexico, Dec. 11-17. For information address: Laboratorio de Anatomia Patologica, Instituto N. de Cardiologia, Avenida Cuauhtemoc 300, Mexico 7, D. F., Mexico.

Latin American Congress of Physical Medicine, San Juan, Puerto Rico and Curacao, N.W.1., Jan. 29-Feb. 8, 1956. Dr. Cassius Lopez de Victoria, 176 East 71st St., New York 21, New York, U. S. A., Executive Director.

Medical Women's International Association, Extraordinary General Assembly, Burgenstock, Nidwalden, Switzerland, Sept. 21-23, 1956. Dr. Janet Aitken, 30a Acacia Road, London N.W. 1, England, Secretary.

North Queensland Medical Conference, Cairns, North Queensland, Australia, June 25-30, 1956. Dr. W. R. Horsfall, P.O Box 672, Cairns, N.Q., Australia, Secretary.

Pan-American Academy of General Practice, San Juan, Puerto Rico and Curacao, N.W.1., Jan. 29-Feb. 8, 1956. Dr. Arturo Martinez, 54 East 72d St., New York 21, New York, U. S. A., Secretary.

Pan American Congress of Gastroenterology, Havana, Cuba, Jan. 20-27, 1956. For information address: Dr. Norberto M. Stapler, 1267 J. E. Uriburu, Buenos Aires, Argentine, S. A.

Pan American Congress of Ophthalmology, Santiago, Chile, S. A , Jan. 9-14, 1956. Dr. Rene Contardo, Huerfanos 930, Of. 74, Santiago, Chile, Secretary General.

Pan American Congress of Otorhinolaryngology and Bronchoesophagology, San Juan, Puerto Rico, April 8-12, 1956. Dr. C. E. Munoz MacCormick, Apartado 9111, Santurce 29, Puerto Rico, Secretary General.

Pan American Medical Women's Alliance, Santiago, Chile, March 6-13, 1956. For information address: Dr. Eva Cutright, 458 Beall Ave., Wooster, Ohio, U. S. A.

World Congress on Fertility and Sterility, Naples, Italy, May 18-26, 1956. For information address: Prof. G. Tesauro, S. Andrea della Dame, 19, Naples, Italy.

World Medical Association, Havana, Cuba, Oct. 9-15, 1956. Dr. Louis H. Bauer, 345 East 46th St., New York 17, New York, U. S. A., Secretary-General.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Various Centers. April 24-25 (Part II); June 19-20 (Parts I and II); September 4-5 (Part I). Candidates may file applications at any time but they must be received at least six weeks before the date of the examination for which application *is made. New candidates should apply by formal registration;* registered candidates may notify the board, indicating desired location, date and candidate number. Ex. Sec., Dr. John P. Hubbard, 133 South 36th St., Philadelphia 4.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 19-21. Sec., Dr. D. G. Gill, State Office Bldg., Montgomery.

Arizona:* *Examination.* Phoenix, Jan. 18-19. *Reciprocity.* Phoenix, Jan. 21. Sec., Dr. M. R. Richter, 411 Security Bldg., Phoenix.

Delaware: *Examination.* Dover, Jan. 10-12. *Reciprocity.* Dover, Jan. 19. *Sec., Dr. Joseph S. McDaniel, Dover.*

District of Columbia:* *Reciprocity.* Washington, Dec. 12. Deputy Director, Mr. Paul Foley, 1740 Massachusetts Ave. N.W., Washington 6.

Georgia: *Examination and Reciprocity*. Atlanta, June. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

Idaho: *Examination and Reciprocity*. Boise, Jan. 9-11. Exec. Sec., Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Illinois: *Examination and Reciprocity*. Chicago, Jan. 24-26. Supt. of Regis., Mr. Frederic B. Selcke, Capitol Building, Springfield.

Indiana: *Examination*. Indianapolis, June. Exec. Sec., Miss Ruth V. Kirk, 538 K. of P. Bldg., Indianapolis.

Maryland: *Examination*. Baltimore, Dec. 13-16. Exec. Sec., Miss Hannah A. McCarthy, 1215 Cathedral St., Baltimore 1.

Michigan:* *Examination*. Ann Arbor and Detroit, June 13-15 (Tentative). Sec., Dr. E. C. Swanson, 118 Stevens T. Mason Bldg., Lansing.

Minnesota:* *Examination*. Minneapolis, Jan. 18-20. Sec., Dr. F. H. Magney, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: *Reciprocity*. Jackson, December. Asst. Sec., Dr. R. N. Whitfield, State Board of Health, Jackson.

Montana: *Examination and Reciprocity*. Helena, April 3-4. Sec., Dr. S. A. Cooney, 7 West 6th Ave., Helena.

Nebraska:* *Examination*. Omaha, June 18-20. Director, Bureau of Examining Boards, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

Nevada:* *Examination and Reciprocity*. Reno, Jan. 3. Sec., Dr. G. H. Ross, 112 N. Curry St., Carson City.

New Hampshire: *Examination and Endorsement*. Concord, March 14. Sec., Dr. John S. Wheeler, 107 State House, Concord.

New York: *Examination*. Albany, Buffalo, Syracuse and New York, Feb. 7-10. Sec., Dr. Stiles D. Ezell, 23 S. Pearl St., Albany.

North Carolina: *Reciprocity*. Durham, Jan. 16. Sec., Dr. Joseph J. Combs, Professional Bldg., Raleigh.

North Dakota: *Examination*. Grand Forks, Jan. 4-6. *Reciprocity*. Grand Forks, Jan. 7. Sec., Dr. C. J. Glaspel, Box 228, Grafton.

Ohio: *Examination*. Columbus, Dec. 15-17. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Oklahoma:* *Examination*. Oklahoma City, June 5-6. Sec., Dr. E. F. Lester, 813 Braniff Bldg., Oklahoma City.

Oregon:* *Examination*. Portland, Jan. 12-14. Exec. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland.

Pennsylvania: *Examination*. Philadelphia, January. Acting Sec., Miss Marguerite G. Steiner, Box 911, Harrisburg.

Rhode Island:* *Examination*. Providence, Jan. 5-6. Admin. of Professional Education, Mr. Thomas B. Casey, Room 366, State Office Bldg., Providence 2.

South Dakota:* *Examination*. Sioux Falls, Jan. 17-18. Exec. Sec, Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Tennessee:* *Examination*. Memphis, Dec. 21-22. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis.

Washington:* *Examination*. Seattle, Jan. 9-11. *Reciprocity*. Seattle, Jan. 8. Secretary, Department of Licenses, Mr. Edward C. Dohm, Olympia.

West Virginia: *Examination and Reciprocity*. Charleston, Jan. 9-11. Sec., Dr. Newman H. Dyer, State Office Bldg., No. 3, Charleston 5.

Wisconsin:* *Reciprocity and Examination*. Madison, Jan. 10-12; *Reciprocity*, Madison, Spring; *Reciprocity and Examination*. Milwaukee, July 10-12. Sec., Dr. Thomas W. Tormey, Jr., 1140 State Office Bldg., Madison.

Wyoming: *Examination and Endorsement*. Cheyenne, Feb. 6. Sec., Dr. Franklin D. Yoder, State Office Bldg., Cheyenne.

Alaska:* On application. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

Guam: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Sec., Dr. John E. Kennedy, Agana.

Hawaii: *Examination*. Honolulu, Jan. 9-12. Sec., Dr. I. L. Tilden, 1020 Kapiolani, St., Honolulu.

Puerto Rico: *Examination*. San Juan, Mar. 6-11. Sec., Dr. Joaquin Mercado Cruz, Box 3271, San Juan.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arizona: *Examination and Reciprocity*. Tucson, Dec. 20. Sec., Dr. H. D. Rhodes, University of Arizona, Tucson.

Arkansas: *Examination*. Little Rock, May 4-5. Sec., Mr. S. C. Dellinger, Zoology Department, University of Arkansas, Fayetteville.

District of Columbia: *Examination*. Washington, April 23-24. Deputy Director, Mr. Paul Foley, 1740 Massachusetts Ave. N.W., Washington 6.

Iowa: *Examination*. Des Moines, Jan. 10. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Michigan: *Examination*. Detroit and Ann Arbor, Feb. 10-11. Sec., Mrs. Anne Baker, 410 W. Michigan Ave., Lansing 15.

Minnesota: *Examination*. Minneapolis, Jan. 3-4. Sec., Dr. Raymond N. Bieter, 126 Millard Hall, University of Minnesota, Minneapolis.

Nebraska: *Examination*. Omaha, Jan. 10-11. Sec., Mr. Husted K. Watson, Room 1009, State Capitol Bldg., Lincoln 9.

Nevada: *Examination*. Reno, Jan. 3. Sec., Dr. Donald G. Cooney, Box 9005, University Station, Reno.

New Mexico: *Examination*. Santa Fe, Jan. 15. Sec., Mrs. Marguerite Cantrell, Box 1522, Santa Fe.

Oklahoma: *Examination*. Oklahoma City, Mar. 30-31. Sec., Dr. E. F. Lester, 813 Braniff Bldg., Oklahoma City.

Oregon: *Examination*. Portland, Dec. 3; March 3; June 2, Sept. 8 and Dec. 1. Dr. Earl M. Pallett, Sec., State Board of Higher Education, Eugene.

Tennessee: *Examination*. Memphis, Dec. 30-31. Sec., Mr. O. W. Hyman, 62 S. Dunlap St., Memphis 3.

Texas: *Examination*. Galveston, Dallas, and such other locations as are warranted, April. Sec., Bro. Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

Washington: *Examination*. Seattle, Jan. 4-5. Secretary, Department of Licenses, Mr. Edward C. Dohm, Olympia.

Wisconsin: Madison, Apr. 7. Final date for filing application is Mar. 30. Sec., Dr. W. H. Barber, 621 Ransom St., Ripon.

Alaska: On application. Juneau or other towns in Territory as decided by Board. *Reciprocity*. On application. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

---

*Basic Science Certificate required.

MAGAZINE–TELEVISION REPORT

The following list of current medical articles in mass-circulation magazines and forthcoming network television programs on medical subjects is published each week only for the information of readers of The Journal. *Unless specifically stated, the American Medical Association neither approves nor disapproves of the articles and programs reported.*

TELEVISION

Monday, Dec. 12

NBC-TV, 11 a. m.-12 noon EST. "Medical and Health News with Howard Whitman," a segment of the "Home" show.

ABC-TV, 9:30 p. m. EST. "Medical Horizons" deals with industrial medicine, especially emphasizing the effects of noise on hearing, in a program from the Institute of Industrial Health, University of Michigan Medical Center, Ann Arbor. Presented in cooperation with the American Medical Association.

Tuesday, Dec. 13

ABC-TV, 9:30 p. m. EST. "Dupont Cavalcade Theater" presents "Doctor on Wheels," the story of medical student who becomes a polio victim. Dr. Paul O. Shearer completes his education at the College of Medical Evangelists in a wheel chair and goes into internship in Glendale, Calif.

MAGAZINES

Saturday Evening Post, Dec. 3, 1955

"The Men with Deadly Dreams," by Nils P. Larson, M.D.

From Hawaii a doctor reports on one of the most puzzling mysteries known to medical scientists. Men go to bed in sound health and dream themselves to death.

Parents' Magazine, December, 1955

"What to Do If You Are All Tired Out," by Elizabeth George Speare

This article directed at mothers quotes the president of the Connecticut Heart Association as saying "patients seeking an explanation for fatigue comprise a large part of a physician's practice." The author suggests self-analysis to determine what is causing the fatigue and lists "practical measures" to relieve it.

"How to Stop Baby Feeding Problems Before They Start," by Ruth Newburn Sedam

Pediatricians Dr. Preston A. McLendon, George Washington University Hospital, and Dr. Otto Faust, Albany Hospital, give advice on infant feeding problems.

GOVERNMENT SERVICES

AIR FORCE

Colonel Byrnes Wins Award.—Col. Victor A. Byrnes, M. C., of the Air Force, was presented with the Gorgas medal, Nov. 9, at the military surgeons meeting in Washington for his work in retinal burns due to atomic explosions. The award consists of a silver medal, scroll, and an honorarium of $500. Colonel Byrnes is a flight surgeon and a graduate of the Army Command and General Staff School. At present he is director of professional services, surgeon general's office, Washington, D. C.

NAVY

Committee on Hearing and Bioacoustics.—The armed forces are confronted today with many problems on hearing and bioacoustics that are peculiar to the services. The armed forces-national research council committee on hearing and bioacoustics was organized to provide advice on these unique service problems: effects and control of noise, auditory discrimination, speech, communication, the fundamental mechanism of hearing, and auditory standards. The full committee of about 80 members comprises representatives from the armed forces and civilians appointed by the national research council. The latter group includes engineers and scientists in the fields of acoustics, vibrations, psychology, physiology, and medicine. The British and Canadian governments are represented also. Capt. C. P. Phoebus, M. C., U. S. Navy, was elected chairman of the committee at a meeting of the executive council in Washington on Oct. 24. Dr. Phoebus, a special assistant for biosciences in the office of naval research, succeeds Dr. R. H. Bolt, chairman since the committee was organized in 1953, who is with the acoustics laboratory of the Massachusetts Institute of Technology at Cambridge, Mass.

Reserve Officer Schools.—About 72 Naval Reserve officer schools are located throughout all continental naval districts. The courses available to medical department officers are military justice (2 semesters); personnel administration (1 semester); leadership (1 semester); and administration and education and training (2 semesters). Enrollment is open to any inactive duty Naval Reserve officer in good standing in the Naval Reserve.

This program, which is essentially nonpay, is administered on the basis of an academic year of two semesters, with classes held during September through June. Twenty drills a semester are scheduled, and each officer must attend a minimum of 80% of the periods of instruction and pass examinations given periodically and at the end of the course to complete the course satisfactorily. Promotion and retirement points are credited. Fourteen days active duty for training with pay is available each year to all officers who are enrolled in Naval Reserve officer schools.

PUBLIC HEALTH SERVICE

Dr. Vonderlehr Retires.—Dr. Raymond A. Vonderlehr, medical director of the region four office, U. S. Department of Health, Education, and Welfare, at Atlanta, Ga., retired from active government service Nov. 1 and will be succeeded in that assignment by Dr. W. H. Aufranc. Dr. Vonderlehr, a commissioned officer of the Public Health Service for 30 years, served for five years as medical director in charge of the service's communicable disease center in Atlanta, Ga. Formerly he was assistant surgeon general and chief of the division of venereal disease and quarantine officer for the United States at ports in Europe and the British Isles. He is the co-author of two books: "Plain Words About Venereal Diseases," and "The Control of V. D."

Professor Barany to Lecture.—Prof. Ernst H. Barany of the University of Upsala, Sweden, will lecture Dec. 8, 1955, at the National Institutes of Health, Bethesda, Md. As guest of the Ophthalmology Branch, National Institute of Neurological Diseases and Blindness, he will speak on "Factors Controlling the Resistance to Flow Through the Chamber Angle." All interested persons are invited to attend at 8 p. m. in room 10-N-114, clinical center.

VETERANS ADMINISTRATION

Special Treatment Program for Long-Term Patients.—Long-term veteran patients, some hospitalized 20 years or more, will be concentrated in special sections of Veterans Administration hospitals for a new program of specialized treatment to promote their recovery. The intermediate program, as it is known, is underway in 30 VA hospitals and will be expanded to others as rapidly as they qualify. The objective is to provide active rather than custodial care for those long-term patients in the VA hospital system who no longer need definitive hospital treatment, cannot return home, and lack the capabilities necessary for the new planned-living program in VA domiciliaries.

Specially qualified staffs are required to man these sections. For each long-term patient, a maintenance rehabilitation program will be instituted immediately to retain the benefits of hospital care already given and to prevent the development of disabilities resulting from physical inactivity. Moreover, the section staff will gear a planned activity program to each patient's capacity and need for recreational, spiritual, and social activities. Dr. William S. Middleton, chief medical director, said periodic reviews will be made of each patient's rehabilitation progress with the objective of planning for his discharge when indicated.

The program first underwent extensive tests in five combination hospital and domiciliary centers. When these tests proved successful, the program was expanded to the 30 hospitals now using it. A study recently completed indicates that 4,282 long-term patients in VA hospitals already meet the criteria for admission to these specialized sections in general medical and surgical hospitals and that 3,917 domiciliary members also are eligible and would be benefited by the increased medical care afforded in such sections.

The problem of caring for the aging and chronically ill patients in VA hospitals has been under special study for several years, and the current program has resulted from these studies. The need to develop long-range plans to cope with this problem is inherent in the present veteran population of 22,000,000, according to Dr. Middleton, since a considerable number will eventually require long-term hospital care. He said 584,000 veterans now are 65 years of age, but only five years hence the number is expected to exceed 1,780,000.

The average age of the 110,000 veterans in VA hospitals is 48, in comparison with the average of 38 years for the veteran population as a whole. About 10,000 VA patients are over 65. About 34,000 of VA's current load of 110,000 patients have been hospitalized for more than five years, with some 9,000 of the 34,000 having been hospitalized for 20 years or more. Because of this existing load, Dr. Middleton said the intermediate program for the present will be primarily restricted to patients and domiciliary members already in the VA hospital and domiciliary system.

Hospital News.—Dr. Thomas A. C. Rennie, New York City, addressed the staff of the VA Hospital at Northport, L. I., New York, Nov. 3 on "The Emergence of Social Psychiatry as a New Branch of Psychiatry: Theory and Research Findings."

DEATHS

Bohan, Peter Thomas ⊕ Kansas City, Mo.; born in Seaton, Ill., Jan. 16, 1874; Rush Medical College, Chicago, 1900; specialist certified by the American Board of Internal Medicine; since 1946 emeritus professor of medicine at the University of Kansas School of Medicine, where he joined the faculty as instructor of medicine in 1908, became professor of medicine in 1914, was acting chairman of the department of medicine from 1917 to 1919, and in 1946 its alumni established the annual Bohan Lecture in appreciation of his services as a teacher; formerly served on the state board of health; at one time vice-president of the Missouri State Medical Association; first president of the Kansas City Heart Association; past-president of the Kansas City Southwest Clinical Society; founding member of the Kansas City Academy of Medicine; an active member of the executive staff at St. Luke's Hospital; on the staffs of the Kansas City General, St. Mary's, and St. Margaret's hospitals; died Oct. 2, aged 81, of acute myocardial infarct.

Block, Siegfried ⊕ New York City; born in Berne, Switzerland, Sept. 22, 1882; Long Island College Hospital, Brooklyn, 1905; for many years on the faculty of his alma mater; specialist certified by the American Board of Psychiatry and Neurology; fellow of the American College of Physicians; member of the American Psychiatric Association; served as consultant for the board of education of New York City and the Court of Special Sessions; chief neuropsychiatrist, Greenpoint Hospital, Brooklyn, where he was formerly president of the medical board; attending neuropsychiatrist, Brooklyn Hebrew Home and Hospital for the Aged, and Menorah Home and Hospital for the Aged and Infirm in Brooklyn; consulting neuropsychiatrist, Samaritan Hospital and Hospital of the Holy Family in Brooklyn; died in the Montefiore Hospital Oct. 18, aged 73, of myocardial infarction.

Senger, William, Beulah, Colo.; born in Port Jervis, N. Y., June 8, 1874; Yale University School of Medicine, New Haven, 1901; an associate member of the American Medical Association; member of the Western Surgical Association; fellow of the American College of Surgeons; past-president of the Pueblo County Medical Society and the Colorado State Medical Society; member of the founders group of the American Board of Surgery; for many years practiced in Pueblo, where he was past-director of school district number 20, past vice-president of the Western National Bank, chief surgeon for the Colorado Fuel and Iron Corporation, and on the staffs of the Colorado State Hospital, St. Mary Hospital, and the Corwin Hospital, where he died Sept. 5, aged 81, of dissecting aortic aneurysm and arteriosclerosis.

Raycroft, Joseph Edward, Princeton, N. J.; born in Williamstown, Vt., Nov. 15, 1867; Rush Medical College, Chicago, 1899; associate professor of hygiene and physical education at the University of Chicago from 1899 to 1911; on the faculty of his alma mater from 1899 to 1904; from 1911 to 1936 professor of health and physical education at Princeton University; past-president and member of the council of the American Student Health Association; an associate member of the American Medical Association; for many years advisor for the New Jersey Department of Institutions and Agencies; member of the board of managers and later president of the New Jersey State Hospital in Trenton, where he died Sept. 30, aged 87, of cardiorenal vascular disease.

Porter, William Clare, colonel, U. S. Army, retired, Los Lunas, N. Mex.; born in Binghamton, N. Y., July 28, 1886; Albany (N. Y.) Medical College, 1907; entered the Medical Corps of the U. S. Army in 1918 and retired in April, 1947; attained the rank of colonel Oct. 19, 1942; director, school of military neuropsychiatry at Lawson General Hospital, Atlanta, Ga., from 1942 to 1946, and at Fort Sam Houston, Texas, 1946-1947; specialist certified by the American Board of Psychiatry and Neurology; fellow of the American Psychiatric Association; since 1947 superintendent and medical director of the Los Lunas Mental Hospital; died in the Presbyterian Hospital, Albuquerque, N. Mex., Sept. 24, aged 69.

Culver, Wesley Youngs ⊕ Katonah, N. Y.; born in Westhampton Beach Jan. 16, 1909; Vanderbilt University School of Medicine, Nashville, Tenn., 1937; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; served during World War II; interned at the Flushing (N. Y.) Hospital and Dispensary; formerly a resident physician at the Pilgrim State Hospital in Brentwood, Institute of Living in Hartford, Conn., and the New York State Psychiatric Institute and Hospital in New York City; clinical director of the Four Winds; died in Westhampton July 11, aged 46, of acute myocardial infarction and arteriosclerosis.

Newell, Horatio Whitman, Baltimore; born Feb. 5, 1898; Western Reserve University School of Medicine, Cleveland, 1926; associate professor of psychiatry at the University of Maryland School of Medicine and College of Physicians and Surgeons; specialist certified by the American Board of Psychiatry and Neurology; member of the Medical and Chirurgical Faculty of Maryland, the American Psychoanalytic Association, and the American Psychiatric Association; past-president of the American Orthopsychiatric Association; served during World War II; consultant at the University Hospital; died Aug. 19, aged 57, of heart disease and emphysema.

Heaney, Noble Sproat ⊕ Los Angeles; Rush Medical College, Chicago, 1904; clinical professor of obstetrics (Rush) emeritus, University of Illinois College of Medicine, Chicago; specialist certified by the American Board of Obstetrics and Gynecology; past-president of the American Gynecological Society; member of the Institute of Medicine of Chicago; fellow of the American College of Surgeons; at one time practiced in Chicago, where he was on the staff of the Presbyterian Hospital; on the staffs of the Presbyterian Hospital-Olmsted Memorial, Temple Hospital, and the Cedars of Lebanon Hospital; died Sept. 26, aged 75, of cerebral thrombosis.

Cross, James Bailey, Buffalo; born in 1882; Columbia University College of Physicians and Surgeons, New York City, 1907; an associate member of the American Medical Association; fellow, past-president, and for many years treasurer of the American Urological Association; past-president of the Buffalo Academy of Medicine; fellow of the American College of Surgeons; specialist certified by the American Board of Urology; consultant, J. N. Adam Memorial Hospital at Perrysburg and the Buffalo State Hospital; attending urologist at Millard Fillmore Hospital and the Deaconess Hospital, where he died Oct. 9, aged 73, of coronary thrombosis.

McBroom, David Edward, Faribault, Minn.; born in Akron, Ohio, Dec. 31, 1883; Ohio Medical University, Columbus, 1907; specialist certified by the American Board of Psychiatry and Neurology; past-president of the Minnesota Medical Officers' Association and the East Central Minnesota Medical Society; superintendent of the Minnesota Colony for Epileptics in Cambridge from 1928 to 1944 and the South Dakota School and Home for Feebleminded in Redfield from 1944 to 1948; served on the staff of the Minnesota School and Colony; died in Minneapolis Sept. 3, aged 71, of coronary thrombosis and arteriosclerosis.

Reynolds, Edna Marguerite, Denver; University of Colorado School of Medicine, Denver, 1930; served on the faculty of her alma mater; specialist certified by the American Board of Ophthalmology; an associate member of the American Medical Association; member of the American Academy of Ophthalmology and Otolaryngology; served as secretary of the Denver Society of Ophthalmology; on the staffs of Denver General, Colorado General, St. Luke's, and Childrens hospitals, and the Porter Sanitarium and Hospital; died in Pueblo Sept. 25, aged 65, of uremia.

⊕ Indicates Member of the American Medical Association.

Abbitt, John Willis ⊕ Portsmouth, Va.; University of Maryland School of Medicine, Baltimore, 1910; past-president of the medical staff of the Kings Daughters Hospital, where he was formerly a member of the board of directors; chief of surgery and chief of the staff of the Maryview Hospital; died Sept. 26, aged 69, of acute coronary thrombosis.

Berry, Frederick Aymond ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; on the staffs of the Evangelical and Englewood hospitals; died in the Albert Merritt Billings Hospital Oct. 11, aged 74, of carcinoma of the esophagus.

Branson, Edward Carl ⊕ Captain, U. S. Army, Washington, D. C.; University of Tennessee College of Medicine, Memphis, 1947; interned at John Gaston Hospital in Memphis, Tenn.; served a residency at the Receiving Hospital of the City of Detroit and the Walter Reed Army Hospital; formerly taught anatomy at his alma mater; entered the regular army in January, 1951; died in Orange Park, Fla., June 3, aged 31, of pulmonary edema with focal hemorrhage.

Brunner, Hans ⊕ New York City; Medizinische Fakultät der Universität, Vienna, Austria, 1919; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; at one time on the faculty of University of Illinois College of Medicine; died July 15, aged 62, of cancer.

Bry, Martin Edwin, New York City; Yale University School of Medicine, New Haven, 1912; member of the Medical Society of the State of New York; died Sept. 11, aged 64.

Cadman, Robert Blakemore ⊕ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1923; certified by the National Board of Medical Examiners; served in France during World War I; on the staff of the Chestnut Hill Hospital, where he died Sept. 27, aged 59, of myocardial infarction and coronary thrombosis.

Caples, Byron H. ⊕ Reno, Nev.; University and Bellevue Hospital Medical College, New York City, 1903; member of the American Urological Association; served during World War I; director of the division of venereal disease control of the Nevada state department of health for many years; died in St. Mary's Hospital Oct. 6, aged 78, of arteriosclerotic heart disease and hypertension.

Chapin, Charles William ⊕ Greene, N. Y.; Albany (N. Y.) Medical College, 1904; for many years member and president of the school board; health officer of consolidated district of Greene; died in the Binghamton (N. Y.) City Hospital Sept. 16, aged 79, of ruptured abdominal aneurysm and pernicious anemia.

Coghlan, Jasper, East Orange, N. J.; New York Homeopathic Medical College and Hospital, New York City, 1900; served during World War I; associated with the East Orange General Hospital; died Oct. 3, aged 79, of cardiovascular renal disease.

Crouch, John Baker, Colorado Springs, Colo.; Northwestern University Medical School, Chicago, 1905; an associate member of the American Medical Association and in 1935 a member of its House of Delegates; first vice-president of the American Academy of Tuberculosis Physicians; member of the American Trudeau Society and formerly member of its council; on the staffs of the Glockner Penrose Hospital, St. Francis Hospital, and the Memorial Hospital; died Sept. 18, aged 74, of cerebral thrombosis.

Crutchfield, Pinkney Herman, Stamping Ground, Ky.; Kentucky School of Medicine, Louisville, 1893; an associate member of the American Medical Association; died in Georgetown Aug. 7, aged 85.

Drant, Patricia Hart ⊕ Westtown, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1920; specialist certified by the American Board of Dermatology and Syphilology; member of the American Academy of Dermatology and Syphilology; fellow of the American Association for the Advancement of Science; on the staff of the Abington (Pa.) Memorial Hospital, Methodist and Woman's hospitals in Philadelphia; died in the Bryn Mawr (Pa.) Hospital Oct. 3, aged 59.

Durkee, John Watson, Morristown, N. J.; Columbia University College of Physicians and Surgeons, New York City, 1895; an associate member of the American Medical Association; member of the Medical Society of the State of New York and the American Laryngological, Rhinological and Otological Society; fellow of the American College of Surgeons; specialist certified by the American Board of Otolaryngology; died July 6, aged 86.

Fletcher, Asa E., Omaha; Indiana University School of Medicine, Indianapolis, 1911; died July 17, aged 73, of cerebral hemorrhage and hypertension.

Friedman, Harry Jacob, New York City; Columbia University College of Physicians and Surgeons, New York City, 1903; member of the Medical Society of the State of New York; died in the Manhattan State Hospital July 18, aged 74, of coronary thrombosis.

Haggerty, Daniel Leo ⊕ Trenton, N. J.; Georgetown University School of Medicine, Washington, D. C., 1915; fellow of the American College of Surgeons; past-president of the Mercer County Medical Society; served during World War I; on the staff of the St. Francis Hospital; died in Morrisville, Pa., Oct. 8, aged 61, of cerebral vascular hemorrhage.

Hall, Earl Stanley, Westbrook, Maine; Medical School of Maine, Portland, 1920; an associate member of the American Medical Association; died in the Mercy Hospital, Portland, Aug. 19, aged 64, of cerebral hemorrhage.

Hopkins, Thomas Andrews ⊕ St. Louis; Missouri Medical College, St. Louis, 1894; at one time vice-president and secretary of the St. Louis Medical Society; served on the staffs of the state hospital in Fulton and Nevade, Mo.; died in the Deaconess Hospital Sept. 23, aged 88.

Jerrell, Paul Mahlon ⊕ St. Cloud, Minn.; University of Michigan Medical School, Minneapolis, 1923; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; on the staff of the Veterans Administration Hospital; died July 24, aged 59, of reticulum cell sarcoma.

Libert, John Nicholas ⊕ St. Cloud, Minn.; Creighton University School of Medicine, Omaha, 1916; in 1925 vice-president of the Minnesota State Medical Association; past-president of the Stearns-Benton Counties Medical Society, of which he was secretary for many years; served during World War I; county coroner; on the staff of St. Cloud Hospital; died in Abbott Hospital, Minneapolis, Sept. 2, aged 62, of acute coronary insufficiency.

McClintock, John Thomas ⊕ Iowa City; State University of Iowa College of Medicine, Iowa City, 1898; professor emeritus of physiology at his alma mater, where from 1897 to 1901 he was demonstrator of pathology and anatomy, later professor and head of the department of physiology, for many years junior dean, and at one time chairman of the administrative committee; past-president of the Johnson County Medical Society; died Sept. 24, aged 82, of arteriosclerotic heart disease.

Meriwether, Lodwick Sterrett, New Orleans; University of Virginia Department of Medicine, Charlottesville, 1931; served during World War II; member of the Louisiana State Medical Society; died in Sunset, La., Sept. 11, aged 54, of coronary occlusion.

Moerke, Robert Frank ⊕ Burlington, Iowa; State University of Iowa College of Medicine, Iowa City, 1934; president of the Des Moines County Medical Society; county health officer; served during World War II; on the staffs of the Burlington and Mercy hospitals; died Sept. 28, aged 48, of leukemia.

Moore, Loyal Hamilton, McAllen, Texas; College of Physicians and Surgeons, Baltimore, 1910; past-president of the Hidalgo-Starr Counties Medical Society; died July 8, aged 72, of coronary thrombosis.

Muldoon, Wilfried Edward ⊕ San Antonio, Texas; University of Michigan Medical School, Ann Arbor, 1922; specialist certified by the American Board of Ophthalmology; served during World War I; on the staffs of the Nix Memorial, Brooke Army, and Santa Rosa hospitals; died Oct. 3, aged 58, of congestive heart disease.

Mullen, Lawrence George ⊕ Cambridge, Mass.; Tufts College Medical School, Boston, 1934; member of the American Academy of General Practice; served overseas during World War II; on the staffs of the Cambridge City Hospital and the Mount Auburn Hospital, where he died Oct. 11, aged 46.

Niles, Charles Milton, Forest Lake, Minn.; Chicago Homeopathic Medical College, 1900; died in the Bethesda Hospital, St. Paul, July 17, aged 77, of acute coronary thrombosis.

Noe, Philip R. ⊕ Centralia, Ill.; Milwaukee Medical College, 1912; died July 16, aged 70, of coronary thrombosis.

O'Donnell, George Thomas, Wethersfield, Conn.; Harvard Medical School, Boston, 1897; at one time deputy commissioner of tuberculosis for the city of Boston; died in St. Francis Hospital, Hartford, Oct. 3, aged 80, of nephritis.

Olson, Ole Hansteen, Erskine, Minn.; Rush Medical College, Chicago, 1886; died Sept. 25, aged 92, of nephrosclerosis and uremia.

Pattengill, Morrell, Cisco, Ill.; Rush Medical College, Chicago, 1895; died in the Decatur and Macon County Hospital in Decatur Oct. 7, aged 87, of heart disease.

Pearlstein, Phillip, Peekskill, N. Y.; University of Maryland School of Medicine, Baltimore, 1912; died Oct. 4, aged 75, of acute coronary occlusion.

Perkins, Ralph Sherburne ⊕ Harwich Port, Mass.; Johns Hopkins University School of Medicine, Baltimore, 1911; member of the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; past-president of the Worcester District Medical Society; served during World War I; consulting orthopedic surgeon, Worcester City and Worcester Hahnemann hospitals in Worcester, Holden District Hospital in Holden, and Harrington Memorial Hospital in Southbridge; died in Cape Cod Hospital in Hyannis Oct. 2, aged 60, of myocardial infarction.

Petit, William Daugherty ⊕ Presidio, Texas; Washington University School of Medicine, St. Louis, 1911; served in the regular Army and during World War I; died in the William Beaumont Army Hospital, El Paso, July 17, aged 71, of pulmonary infarction.

Post, Samuel James, Center Moriches, N. Y.; Long Island College Hospital, Brooklyn, 1912; member of the Medical Society of the State of New York and the American College of Chest Physicians; died Aug. 1, aged 72, of arteriosclerotic heart disease.

Ridgway, Eldo T., Lebanon, Ill.; the Hahnemann Medical College and Hospital, Chicago, 1906; for many years practiced in Elkhorn, Wis., where he was mayor; served as state senator of Wisconsin; died Oct. 12, aged 74.

Rimson, Oscar, Cleveland; Tufts College Medical School, Boston, 1929; interned at the Morrisania City Hospital in New York City; formerly resident physician at the Sea View Hospital in Staten Island, N. Y.; died in the Highland View Cuyahoga County Hospital Sept. 14, aged 50, of pneumonia.

Sauer, David Eric ⊕ Lubbock, Texas; University of Cincinnati College of Medicine, 1937; interned and served a residency at the Youngstown Hospital; member of the American Academy of General Practice and the Texas Academy of General Practice; formerly a resident at the Medical Arts Hospital in Dallas; on the staffs of the Methodist, West Texas, and St. Mary's hospitals; died in St. Joseph's Hospital, Denver, Oct. 9, aged 45, of coronary insufficiency.

Schantz, Henry Franklin, Reading, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1891; served during World War I; on the staff of the Community General Hospital, where he died Sept. 13, aged 86, of congestive heart disease.

Schillander, Carl Axel, Fort Lauderdale, Fla.; Tufts College Medical School, Boston, 1910; member of the Massachusetts Medical Society; practiced in Springfield, Mass.; served during World War II; died July 30, aged 66, of acute myocardial infarction.

Schurgot, James Adam, Grafton, Ohio; University of Pittsburgh School of Medicine, 1914; on the staff of the Elyria (Ohio) Memorial Hospital; died in Cleveland Sept. 30, aged 66, of carcinoma of the stomach.

Self, William Osce, Columbia, S. C.; Duke University School of Medicine, Durham, N. C., 1937; interned at the Johns Hopkins Hospital, Baltimore; served a residency at the Palmerton (Pa.) Hospital; certified by the National Board of Medical Examiners; member of the American Academy of General Practice; died in the Columbia Hospital Sept. 29, aged 43.

Slabotsky, Samuel, Central Village, Conn.; Eclectic Medical University, Kansas City, Mo., 1918; Kansas City (Mo.) College of Medicine and Surgery, 1920; died in Veterans Administration Hospital, Montrose, N. Y., July 6, aged 63, of infarction of the myocardium.

Smith, Leonard Higbie ⊕ East Orange, N. J.; University and Bellevue Hospital Medical College, New York City, 1903; fellow of the American College of Surgeons; for many years on the staff of the Orange Memorial Hospital; died in Madison Oct. 8, aged 78, of a cerebral vascular accident.

Sopher, Curtis Levi ⊕ Wakefield, Mass.; University of Vermont College of Medicine, Burlington, 1890; fire department physician, chairman of the board of health, planning board member, and for many years commissioner of the municipal lighting department; died Oct. 5, aged 89.

Steward, Rebecca Viola Ditzler, Merriam, Kan.; Kansas City Homeopathic Medical College, 1898; died Sept. 19, aged 89, of heart disease.

Toney, Sherwood M., Bennington, Okla. (licensed in Oklahoma under the Act of 1908); died July 12, aged 74, of cancer.

Turner, Kenneth Burlen ⊕ New York City; Harvard Medical School, Boston, 1926; associate professor of medicine (clinical medicine) at Columbia University College of Physicians and Surgeons; member of the Association of American Physicians and the American Society of Clinical Investigation; certified by the National Board of Medical Examiners; on the staff of the Presbyterian Hospital; died Oct. 9, aged 54, of cerebral hemorrhage.

Vaccari, Zeferino, Huntington Station, N. Y.; Regia Università degli Studi di Palermo, Facoltà di Medicina e Chirurgia, Italy, 1920; died July 23, aged 62, of pulmonary embolism, septicemia, and arteriosclerotic encephalomalacia.

Vardy, Philip L., Estelline, Texas; Missouri Medical College, St. Louis, 1897; member of the State Medical Association of Texas; local health officer; on the staff of the Childress (Texas) General Hospital; died Aug. 30, aged 84, of coronary thrombosis.

Verdeschi, Felix L. ⊕ Ozone Park, N. Y.; New York Medical College, Flower and Fifth Avenue Hospitals, New York City, 1928; on the staffs of the Physicians Hospital in Plattsburg and the Mary Immaculate Hospital in Jamaica, where he died Sept. 10, aged 53, of coronary disease.

Vloedman, Derk Andrew ⊕ Woodward, Okla.; Loyola University School of Medicine, Chicago, 1925; served during World War I; for many years taught at his alma mater; at one time practiced in Blue Island, Ill., where he was president of the board of education, district 130, from 1946 to 1952; formerly on the staffs of the Ingalls Memorial Hospital in Harvey and St. Bernard and St. George hospitals in Chicago; on the staff of Memorial Hospital; died Oct. 6, aged 56, of ruptured aortic aneurysm.

Wagner, Earl Calvin ⊕ Tupper Lake, N. Y.; Syracuse University College of Medicine, 1908; member of the American Society of Anesthesiologists; died Sept. 12, aged 68, of coronary arteriosclerosis.

Walter, Ralph Somers, Harrisburg, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1920; died in the Harrisburg Hospital Aug. 28, aged 65, of bronchiectasis.

Welch, Gilford Nelson ⊕ Centralia, Ill.; National University of Arts and Sciences Medical Department, St. Louis, 1914; died June 28, aged 65, of coronary thrombosis.

FOREIGN LETTERS

CHILE

Amebic Rectosigmoiditis.—Dr. B. Biel in the May issue of the *Revista médica de Chile* reports on a series of 91 patients, aged 13 to 76 years, with intestinal amebiasis. Twenty-two patients also had a bacteriological study before and after treatment. Three clinical types of the disease were observed: (1) acute or chronic dysentery with an exacerbation; (2) nondysenteric chronic diarrhea; and (3) a nondiarrheal form. About 50% of the patients belonged in group one; 28% in group two; and 22% in group three. The proctoscopic findings were classified as: ulcerative, congestive-granular, simple congestive, small miliary abscesses, or normal. Ulcers were found in 32% of the patients (48% of those with acute dysentery; 11% of those with the nondysenteric form; and 21% of those with the nondiarrheal form). In 45% of all patients, the congestive-granular form was observed, this being the most frequent form (present in 39% of the patients with dysenteric symptoms; 46.5% of those with nondysenteric diarrheas; and in 57% of those with nondiarrheal amebiasis). The simple congestive type was found in only 3%; small miliary abscesses were found in 4.3%; and normal-appearing mucosa was found in 15% but never in patients with dysentery. Shigella sonnei was found in the stools of two patients. The results of treatment cannot be judged exclusively on the proctoscopic appearance. At the end of treatment with antibiotics the author observed (1) clinical healing with normal mucosa and no amebas in the stools; (2) clinical healing with no amebas in the stools but persistence of a granular mucosa; (3) persistence of pathological proctoscopic findings and/or amebas in the stools; and (4) congestion of the mucosa but no amebas in the stools. Thus, positive post-therapeutic proctoscopic findings combined with the absence of other factors must not be considered important; their meaning requires further study. However, it is the presence or absence of Endameba histolytica in stools that determines if the patient is cured.

Dioxyline Phosphate for Arterial Insufficiency.—Dr. Otto Herrmann in the July issue of the *Revista chilena de angeologia* reported on 18 patients (mostly men) treated with dioxyline phosphate. Obliterating arteriosclerosis of the extremities was present in 15, arterial emboli in 2, and Raynaud's disease in one. Thirteen of the patients smoked an average of 30 cigarettes daily; 14 complained of claudication, 13 had paresthesias, and 13 complained of coldness of the extremities. The distance a patient could walk before claudication appeared varied from 50 to 500 m. (164 to 1640 ft.). The average duration of the disease prior to the initiation of treatment was two years and two months. Physical examination revealed absence of pulse, pallor, cyanosis, coldness of the extremities, and absence, or decrease, of oscillometric readings. In this series there were no mild cases; two were moderately severe; nine were severe; and seven were very severe. Twelve patients had manifestations of arteriosclerosis in other parts of the body, coronary disease, heart failure, or hypertension. One had diabetes, but this was controlled. Dioxyline phosphate was given twice daily for two weeks. The double blind method of control was used. When treated with dioxyline phosphate the 14 patients with claudication increased their range by at least 6 times, some even by 15 times. The effect on claudication started between the 5th and 10th day of treatment and reached its maximum between the 10th and 20th day. Trophic pain present in 10 patients also began to decrease, and coldness of the extremities, which existed in 13 patients prior to treatment, disappeared in 10 and was markedly relieved in the 3 remaining patients. Similar results were obtained regarding paresthesias. Local temperature became normal in half of the patients and increased significantly in the remaining half. The use of placebos did not benefit the patients.

Infant Diarrhea.—A series of 126 infants under one year of age with diarrhea were examined proctoscopically by Dr. M. Vera (*Revista chilena de pediatria*, March). The duration of the diarrhea prior to the examination was less than 10 days. Second grade dystrophy was present in 66% of the infants, and the diagnosis on admission was severe nutritional disorder (75% had toxicosis or dyspepsia with severe dehydration). The following types of proctosigmoiditis were observed on proctoscopic examination: (1) catarrhal congestive, with a pathological congestion, easy bleeding, with or without edema, and in some a granular appearance; (2) erosive; and (3) ulcerative. Lesions of one of these types were found in 22.4% of the patients, most of them being the catarrhal congestive type. No relation was found between the intensity of the lesions and the severity of the clinical findings, nor could any relation be established between the proctoscopic and the stool examination. The proctoscopic examination of the infant is a simple procedure, provoking only slight distress, but a complete knowledge of the normal appearance of the intestinal mucosa of the infant is necessary because it is quite different from that of the adult; that is, greater thickness and mobility and a deeper pink color, which renders the visualization of the blood vessels more difficult.

Congenital Atresia of the Esophagus.—In *Revista chilena de pediatria* (March, 1955) Garces and Escallon state that congenital atresia of the esophagus with tracheoesophageal fistula-like congenital atresia of the intestine occurs in about one of every 10,000 births. The commonest type is that in which the proximal portion of the esophagus ends as a slightly dilated blind pouch and the distal portion is a narrow tube that communicates with the trachea. In infants so afflicted, there is a flow of mucus from the mouth, precocious regurgitation, attacks of asphyxia, fulness of the epigastrium, constipation, dehydration, and loss of weight. Aspiration bronchopneumonia is a common complication, usually of the right upper lobe. Seven of the authors' eight patients died in the first week of life, and, in all, bronchopneumonia was the cause of death. The clinical diagnosis is based on the characteristic symptoms and may be confirmed by esophageal catheterization and roentgenologic examination using iodized oil. Endoscopy is difficult to perform at this stage of life. The treatment is surgical and consists in the closure of the fistula and an end-to-end anastomosis between the upper and lower segments of the esophagus. The earlier the operation is performed, the better the prognosis. Advances in thoracic surgery have permitted numerous survivals in the last 10 years.

ENGLAND

Restaurant Sanitation.—Wilson and Carter conducted a survey of the sanitary standards in the kitchens of 50 restaurants and canteens in Glasgow (*M. Officer* 94:193, 1955). Unannounced visits were made to these between 1:30 and 2:15 p. m., when kitchen activity was at its highest. Swabs for bacteriological examination were taken of cutlery, crockery, and cooking utensils, and samples of dishwater and dishtowels were collected. Of the 10 kitchens belonging to reputedly high class restaurants, the sanitation was unsatisfactory in 3 and the dishwater was sufficiently hot in only 5; of the 30 restaurants of good everyday type, the sanitation was poor in 10 and washing facilities inadequate in 18; of the 10 kitchens belonging to office or works' canteens, the dishwater was not hot enough in 4. Toilet facilities were also inadequate for the staff in many kitchens, and the usual method of drying the hands was with a communal towel.

The criteria of bacteriological cleanliness laid down were not more than 500 organisms per cubic centimeter in the dishwater and 100 organisms for the whole of the surface swabbed in the case of utensils, cutlery, and crockery. This standard is also prescribed by the United States Public Health Service. Of 42

The items in these letters are contributed by regular correspondents in the various foreign countries.

dishtowels, only 5 yielded bacterial counts of less than 1,000 per square inch; 5 gave counts between 100,000 and 1,000,000. Ten yielded Escherichia coli, and others yielded enterococcus organisms, Clostridium welchii, a coagulase-positive Micrococcus pyogenes var. aureus organism, and nonhemolytic streptococci. Only 10 of 42 samples of dishwater yielded bacterial counts of less than 1,000 per cubic centimeter. The same organisms were isolated from the dishtowels. Ninety plates were examined; 51 had bacterial counts of under 1,000 for the surface swabbed, and 4 had counts of over 1 million. Of 102 articles of cutlery swabbed, 68 had bacterial counts of under 1,000; one spoon had over 1 million organisms on the surface swabbed. Some yielded E. coli, an M. pyogenes var. aureus organism, and nonhemolytic streptococci. Of the cups, 50% yielded counts of under 1,000 for the area swabbed. No Salmonella organisms or hemolytic streptococci were isolated from any of the kitchens, but in 74% of these E. coli organisms were obtained from one or more articles. No dishtowels came up to the prescribed standard. Ventilation was inadequate in 11 of the 50 kitchens examined, and it was here that the worst bacteriological findings occurred. The paramount need in most kitchens was for more hot water of suitable temperature (180 F [82.2 C] or above).

Long-Distance Swimmers.—Pugh and Edholm have investigated the factors concerned in the ability to endure long immersion in cold water (*Lancet* 2:761, 1955). In 1951 there was a swimming race across the English Channel in which 18 competitors swam from France to England in 12 to 20 hours in water at a temperature of 60 F. Their physiological performance was compared with that of normal male athletes. It was concluded that long-distance swimmers tolerate hypothermia better than normal subjects. Rectal temperatures were the same in two of the cross channel swimmers as in a normal athlete who was forced to give up swimming after an hour's exposure, owing to exhaustion and a feeling of muscular weakness. The rectal temperatures of all subjects were in the region of 94 to 96 F (34.4-35.5 C). It was concluded that these long-distance swimmers reach a stable state in which the effective thermal insulation of the outer tissues is such that heat production balances heat loss. In practice swims, the energy output of one of the competitors was measured. This was 310 to 350 calories per square meter per hour, which was comparable with results obtained in nonprofessional swimmers studied under similar conditions. In spite of the identity of heat production, the latter became hypothermic in only half an hour. One long-distance swimmer sat motionless in a bath of 60 F for over an hour without complaining of discomfort. The difference between the thickness of subcutaneous fat of long-distance swimmers and that of normal athletes suggested that cold water tolerance is related to this factor. In one of the swimmers, thermal conduction and heat insulation were measured. Thermal conduction was half that of the normal subject and insulation twice that of the normal subject. Pugh and Edholm attribute these differences to the physique of the swimmers, who were fat, many of them grossly so. Normal subjects cool more rapidly while swimming than while lying still. This suggests that the traditional naval advice in case of shipwreck to cling to wreckage and not to waste energy by swimming or struggling is probably sound.

The Noncalculous Gallbladder.—As a sequel to the celebrations commemorating its 450th anniversary, the Royal College of Surgeons of Edinburgh has launched a journal of its own, the *Journal of the Royal College of Surgeons of Edinburgh,* which is to be published quarterly. The first issue, which is dated September, 1955, contains an article by Sir Heneage Ogilvie in which he advises any young surgeon who would keep the respect of his students, the trust of his colleagues, and the integrity of his conscience to deny the existence of the noncalculous gallbladder and chronic appendicitis, or at least to refuse a fee for operating on them. "Only in middle life when he has . . . set his reputation in an unassailable position by years of honest dealing, may he admit to himself that such lesions do exist, and recommend to patients that they be treated by operation." The author further states that a distressing cause of late common duct obstruction is overcareful technique. There are surgeons in whom the fear of blood loss is carried to such an excess that nothing is divided until it has been doubly ligated, and they are still tying ligatures on hypothetical bleeding points around the common duct long after other surgeons have closed the abdomen and gone home to tea. The result, when at last the operation is finished, is a field that is bloodless but covered with innumerable silk knots, beautifully tied and cut short, but nevertheless irritant foreign bodies. The outcome, years later, is a dense fibrous tissue that may compress and completely obstruct an undivided common duct.

Helicopter for Emergencies.—The value of the helicopter in war for evacuating the wounded was well demonstrated in the Korean campaign. In any future war helicopters are likely to be one of the main means of transport of serious casualties. Their peacetime use in medical emergencies is just being realized. Recently a helicopter brought medical aid promptly to the scene of an accident on board a Dutch vessel off Flamborough Head. A seaman was badly injured, and radio calls for medical assistance brought a medical officer of the Royal Air Force by helicopter, which landed on the deck of the vessel. A helicopter service is of greatest help in isolated districts many miles from expert medical assistance. In parts of Scotland districts are often cut off by snow in the winter so that roads are impassable for a period of time. Last winter in "Operation Snowdrop" supplies were landed in cut-off villages by naval helicopter, and some patients suffering from illness and exposure were rescued by their means. Anticipating that such conditions might arise again, the Scottish North Eastern Regional Hospital Board has now arranged to bear the cost of a helicopter ambulance service operated by naval helicopter from Lossiemouth, which, subject to prior claims by the Navy, will be available for the transport of civilian patients to a hospital in an emergency. A device is now available that enables the helicopter to "scoop" the casualty from the sea, or scene of accident, without landing.

Shortage of Lay Staff in Hospitals.—To obtain and keep a nonmedical staff is a constantly recurring problem for many hospital authorities. There is not only a shortage in the hospitals of pharmacists, radiographers, and medical auxiliaries but also of domestic workers, maintenance engineers, and the like. The shortage of staff is partly a matter of money—a further 28 to 84 million dollars would be required to pay all the additional staff needed—and partly due to difficulty in obtaining personnel. This in turn is attributed to the wage level, fixed by a central controlling authority, which is uniform for any one type of worker in the hospitals all over the country. In industry it is usual for wage agreements to settle minimum rates and to leave each employer free to pay more than the agreement lays down if it is thought desirable. Local conditions may necessitate payments above the minimum. In the hospital service, however, fixed rates are laid down and the individual hospital cannot pay more or less. If an industry is slow to give maximum possible remuneration, optimum working conditions, and chances for promotion and improved status, it may lose some of its workers. Wage rates vary up and down the country, and, in prosperous industrial areas, hospital workers are hard to get because they can obtain better paid industrial jobs in the same area. Some hospitals are also 50 to 100 years old and less pleasant to work in than some modern factories.

Juvenile Suicide.—In 1953 the officially recorded suicides and attempted suicides among children, aged 8 to 17 years, in England and Wales averaged nearly two a week, according to Donald Mulcock (*M. Officer* 94:155, 1955). In the period 1938-1953, there were 357 suicides in this age group, of which 274 (77%) were boys and 83 (23%) were girls. Attempted suicides reported to the police numbered 1,218, of which 786 (64%) were girls and 432 (36%) were boys. Nearly 50% of the boys who committed suicide did so by hanging or self-strangulation; 34% used carbon monoxide; 15% used firearms; and other methods used in order of frequency were drowning, drugs and poisons, and jumping in front of a train. In the case of girls, almost 70% used carbon monoxide; none used hanging or strangulation means. In the period 1935-1949 inclusive, accidental death due to strangulation among children 10-15 years old occurred in 127 boys and 6 girls. Contributing causes included lack of home stability; emotional instability; feelings of being unwanted, unloved, or in the way; pubertal metabolic imbalances; and psychosexual disorders. The author concludes that threats of suicide by juveniles should never be taken lightly. Although 9 times out of 10 it merely indicates bravado, no emotionally healthy child is moved to say such things. Those making such threats should be helped and unobtrusively observed.

Health Insurance.—Addressing the annual meeting in London of the British Hospitals Contributory Schemes in September, the Minister of Heatlh said that about 3,750,000 subscribers to private health insurance plans, or a sixth of the working population, were now enrolled in these schemes and that, if dependents were considered, the number of persons covered was probably 10 million, or a fifth of the population. This was in spite of the National Health Service. The schemes had an income of more than $5,500,000. Any scheme should aim at having as a reserve an amount equal to a year's income. Fifteen schemes had reached this goal, and two-thirds had reserves equal to over 75% of a year's income. The state should never try to run a social service wholly by itself. Voluntary effort helps to bring the hospitals nearer the community. About 1,400 hospitals in the country now have their own League of Friends, or a similar voluntary organization, but 1,000 are without such attachment. It was easy to get voluntary work done in the small local hospital but not so easy in those that a few years ago were public assistance institutions or infirmaries; it was more difficult still in mental hospitals. The Minister of Health said that he thought that some form of National Health Service would come to every country eventually. In some cases it would be run by the government, in others it would be based on insurance schemes.

Signs of Anoxia.—In a study on the acute respiratory infections of childhood, Dr. Brenda Morrison has confirmed that color is a poor guide in diagnosing the lesser degrees of anoxia (*Lancet* **2**:737, 1955). Some healthy children normally have a dusky appearance, while dangerous anoxia may not be accompanied by any appreciable color abnormality, particularly if the patient already has a low hemoglobin level. Oxygen lack was closely correlated with restlessness in the children examined. This restlessness varied with the amount of anoxia present and was pronounced when the oxygen saturation fell below 80%. Restlessness is the outstanding sign of oxygen deficiency in the acute respiratory diseases of childhood. Disturbed sleep for any length of time, persistent crying, repeated flexion and extension of the limbs, rolling of the head, and arching of the back are manifestations of restlessness. Handling, or any interference, is resented. These signs are dramatically relieved, if due to oxygen lack, by the administration of oxygen. An oxygen concentration of 60 to 70% in the ordinary oxygen tent is often required to relieve restlessness. In severe cases 95% oxygen supplied by a face mask, or a special box, may be necessary. Serious anoxia was more common in infants than in older children, and the behavior of the infant was the most valuable clinical guide for the control of oxygen therapy.

Inspection of Doctors' Offices.—At its meeting on Sept. 29, the London Executive Council received a report from the London Local Medical Committee on the inspection of general practitioners' offices begun by the committee in October, 1954. The committee considered that 1,360, or 90.7%, were satisfactory as regards accommodation and equipment. In a further 101 cases, or 6.7%, the premises were for various reasons considered unsatisfactory but had been brought to a satisfactory standard subsequently as a result of suggestions by inspectors. This made a total of 97.4% satisfactory premises. Seven physicians were unable to make their offices satisfactory or to obtain alternative accommodation. In 16 cases the London Executive Council had been asked to inspect the premises because the physician had refused access to inspectors, had refused to comply with requests for improvement, or had delayed in carrying out improvements. Nearly 1,500 premises have been dealt with under the program of inspection. Complaints had been made to the committee that a few patients were guilty of destructive and dirty behavior and of pilfering. Such irresponsibility made it difficult for physicians to maintain adequate standards. There were apparently still cases of hardship caused by bomb damage in the war, and in such cases rehousing was necessary.

Tuberculosis Among National Servicemen.—All national servicemen in the Manchester area were x-rayed by an Army mass miniature radiography unit in March, 1952, February, June, and September, 1953, and March, 1954. The average number of men who underwent radiography on each of these occasions was 444. On each occasion one new case of pulmonary tuberculosis was discovered. None of these men, whose ages were 19 or 20, had had any illness during the period of national service, and all had had previous roentgenograms of the chest 4 to 13 months previously, which had been normal. In reporting these findings in the *Journal of the Royal Army Medical Corps* (**101**:246, 1955) Major Simon Freeman stated that as a result of them the following routine has been established for all service personnel at the Manchester Garrison Medical Center: (1) all must undergo radiography at least once a year; (2) all must undergo radiography before service overseas; (3) all must have a radiological examination of the chest on return from overseas; and (4) all must undergo radiography before demobilization. The last three examinations are made only if there has been no radiological examination of the chest within the preceding three months.

New Penicillin.—Since 1949 mycologists have investigated the antibiotic properties of Cephalosporium. Work in the Michigan Department of Health, Abbott Laboratories, Parke, Davis & Company laboratories, and at the Sir William Dunn School of Pathology, Oxford (*Nature* **176**:551, 1955) has shown that synnematin B and cephalosporin N derived from this source are identical in their activity against micro-organisms, destruction by penicillinase, antibacterial behavior after being run on paper chromatograms in a variety of solvent systems, and products formed after acid hydrolysis. Since they resemble potassium penicillin G in some of their properties, Sir Howard Florey suggests that both be renamed penicillin N, or aminocarboxybutyl penicillin. A number of patients with typhoid and salmonellosis have been successfully treated with these drugs derived from Cephalosporium. It is possible that patients who are sensitive to penicillin G may tolerate these new drugs, in view of the fact that skin tests show that some patients sensitive to the latter do not react to the new antibiotics.

Would-Be-Physicians' English.—At the Westminster Hospital Medical School's prize-giving day on Oct. 3, the dean deplored the low standard of written English of many of the applicants for admission to the medical school. Only 1 in 10 reached the academic and personality standards required by the selection committee of the school. The dean said that any member of the medical profession should be able to put his thoughts on paper clearly and that this could be done only if one had a good command of written English. The contemplated removal of English from the minimum entrance requirements for the medical school (and others) in London University is deplored. In interviewing applicants the dean said that he found very few who devoted more than two brief periods a week to the study of English and that, although several achieved an adequate standard, none achieved a high standard of English; in most the standard was so low that it bordered on illiteracy.

Physicians' Fees for Temporary Residents.—General practitioners in the National Health Service are entitled to a supplementary fee of 70 cents, payable by the state, if called to a patient away from home or because of emergency. Such a patient is called a temporary resident. This fee includes any number of attendances that are necessary after an initial visit. One general practitioner complained of this in the correspondence columns of the *British Medical Journal*. He said that many of the so-called temporary residents called him after consulting hours and at night. In his desire not to split up a family during holidays by sending one of them to the hospital, he may have to make many visits. One case involved 14 visits, including 2 night calls, all for 70 cents. This did not cover gasoline for his car. As a final comment he notes that a small screw was replaced in his refrigerator door. It took 10 minutes, and the charge was just over $1.

Color Blindness.—Using the Ishihara test, W. F. W. Betenson (*M. Officer* **94**:169, 1955) found 243 cases of color blindness in 6,000 boys, aged 10 to 18 years. Of these boys, 53% were green blind, 14% were completely red-green blind, 11% were red blind, 16% were incompletely red-green blind, and in 6% the condition was indeterminate. After the initial test, 211 of these boys had one or more additional tests. It was evident from this retesting that, although in many instances one or two of the plates were read differently by the same boy, the original classification into one of the above-mentioned groups was usually correct. The author urges that testing for color blindness by the Ishihara test be required at all routine school medical inspections.

Whooping Cough Vaccination.—In February, 1953, there was a severe epidemic of whooping cough in London. Dr. Brooks analyzed the incidence of the disease in relation to whether the affected children had been vaccinated against whooping cough (*Month. Bull. Min. Health* **14**:142, 1955). In an estimated population of 2,000 vaccinated children, there were 121 cases of whooping cough, but, in an estimated population of 4,000 unvaccinated children, there were only 149 cases. On the other hand, there were no severe attacks in any vaccinated child, and the proportion of attacks that were "severe or moderate" was 13% in the vaccinated group, compared with 75% in the unvaccinated group.

Proprietary Drugs.—The capital value of Britain's proprietary medicine industry is more than 280 million dollars, according to Mr. H. E. Chapman of the Proprietary Articles Trade Association, who discussed this in an address before the British Pharmaceutical Conference in Aberdeen. The trend in the type of drugs most in demand was indicated by $2,087,232 of the total being spent on analgesics, $1,665,249 on laxatives, $1,456,843 on indigestion remedies, $674,612 on cough and cold remedies, and $536,676 on vitamins. The prescriptions of proprietary preparations in England and Wales have risen from 18% of all prescriptions in 1950 to 31.75% in 1954.

Fluorescent Flicker.—At the 117th annual meeting of the British Association for the Advancement of Science in Bristol in September, Dr. W. F. Floyd of the Middlesex Hospital medical school said that tests given to 30 clerks and typists showed that the slight flicker in fluorescent lighting did not impair their eyesight. These office workers were able to pick out names and numbers from telephone books as well under flickering fluorescent tubes as with ordinary filament lamps. Careful checks on their eyes throughout the four months' experiment showed that no damage was done as a result of working under fluorescent lighting.

FRANCE

Functions of International Congresses.—The Council for International Organizations of Medical Sciences held its third general assembly in Paris on Sept. 30 and Oct. 1. The council was founded in Brussels, Belgium, in 1949 under the joint auspices of UNESCO and the World Health Organization and brings together most of the nongovernmental international organizations in the field of medicine. Its object is to disseminate information that will promote advances in medical science and encourage the application of such knowledge throughout the world. The assembly was concerned with the present trend of international congresses, and it reexamined the real functions of these meetings in the light of the changed situation brought about by specialization and the increased output of scientific research in various fields. On the one hand, the more general congresses were becoming too large, the number of papers read too great, and the opportunities for real discussion too rare. On the other hand, specialization tended to increase the number of meetings, and these specialized meetings often lost contact with their parent disciplines. As international congresses are not the best mediums for reporting scientific discoveries, it was agreed that much could be done to improve the opportunities they offered for personal contacts, for disseminating information to a wide international audience, and for arranging international symposiums and other related activities.

With regard to written communications, it was agreed that there was much duplication between indexing and abstracting services. The difficulties of achieving coordination were recognized, but it was thought that action of limited scope should be undertaken whenever opportunities arose. Standardization of terminology is an important activity that the council would continue to encourage. The assembly decided to promote a shift from individual participation to group participation through precongress working parties and symposiums, or by the appointment of experts to make digests of related communications, through a greater participation of young research workers, and through the holding after a congress of special international courses for the host country, in particular cases. The council will continue to organize symposiums and scientific meetings in underdeveloped countries. The assembly also instructed the executive committee to explore the possibilities of initiating a program in geopathology.

INDIA

"Ayurveda."—In an editorial in the August issue of the *Antiseptic*, Dr. Kirshna Rau stated that public opinion has been strongly rising in favor of *Ayurveda*, a system of medicine supposed to have dated from the 27th century B.C. and extended to about the 10th century A.D. After that it appears to have stagnated, although it has never completely died out. Several eminent physicians, after having practiced modern medicine, have studied *Ayurveda* with great interest and enthusiasm. The Chopra Committee has published a translation, with notes, on the writings of Caraka, pioneer of the Ayurvedic system, and has made extensive study of indigenous plants under a grant from government. Research institutions have been established along modern scientific lines to study *Ayurveda* in relation to modern western medicine. One of the drugs that has created world-wide interest, Rauwolfia serpentina, comes from this indigenous system of medicine. The research institute at Jamnagar has been functioning for over three years, with one team working along purely *Ayurvedic* lines and another along modern western lines. *Ayurveda* flourishes in rural India, where over 85% of the population continues to be treated by this system. Because it is based to a great extent on botanical knowledge and the availability of a wide range of medicinal plants, it has the advantages of being cheap and of using easily available drugs. The protagonists have brought out several arguments in its favor including the sense of patriotism, and antagonists, backed by physicians trained in modern medicine, have considered it ancient and useless. The editorial has tried to show that the truth lies somewhere between the two points of view. If the *Ayurvedic* system is to come into its own again, there must be an integration of it with all that is best in any other system of medicine. This can only be done if *Ayurvedic* institutions develop into active centers of objective research.

Treatment of Hemiplegia.—Bharucha and Ganeshan in the *Journal of Postgraduate Medicine* for July reported on 16 patients with hemiplegia due to vascular accidents who were treated by injecting a 2% solution of procaine into the stellate ganglion soon after the onset of the disease. Successful injection was confirmed by the appearance of Horner's syndrome immediately after the injection was made; eight patients showed definite improvement, and in each there was first a return of power followed by a return of tone, reflexes, and speech. Stellate ganglion block acts by relieving prolonged spasm. Although various accidents including pneumothorax, spontaneous collapse of the lung, and sudden death may occur, only one patient in this series died. Death occurred within a few minutes after the third procaine injection. No autopsy was performed. The maximum improvement occurred in patients who were treated within the first 12 to 24 hours after the onset of hemiplegia. The degree of improvement showed no relationship to age. The block was repeated about every 12 hours until no further improvement was noted; four to six injections were required in most cases.

Primary Lung Cancer.—Although the incidence of primary cancer of the lung is much lower in Bombay than in the western countries, in the last decade it appears from autopsy reports to have steadily increased. The importance of tobacco as a causative factor in India has been studied. In Bombay State alone the average consumption of cigarettes more than doubled between

1949 and 1953. The poorer classes, however, smoke a native product that is a little smaller than a cigarette. Unlike a cigarette, it is not wrapped in paper but in tobacco leaves and the tobacco used is not so highly refined as cigarette tobacco; 96,800,000 lbs. of this unrefined tobacco was consumed in 1950 and 120,200,000 lbs. in 1953 for the whole of India. At a staff meeting of the G.S.M. College and K.E.M. Hospital in Bombay, Dr. D. D. Banker stated that of 9,210 autopsies performed between 1926 and 1953 at the K.E.M. Hospital, 370 cases of malignant disease were found. Of these, 292 were cancer and 78 were sarcoma; only 43 were primary carcinoma of the lung. Secondary malignancy of the lung was found at 60 autopsies. The patient's symptoms had included breathlessness, cough, cachexia, and ascites. In some cases death had occurred within six weeks; the longest survival period without operative treatment was two years, but the average duration of life was six to nine months. Death had been due to cachexia and bronchopneumonia in most of the patients.

Lepromin Test.—In the April issue of the *Bulletin of Calcutta School of Tropical Medicine*, Dharmendra and Chatterjee reported on the prognostic value of the lepromin test in persons who have been exposed to infection from lepers. The lepromin test is useful in determining the prognosis in persons suffering from the disease as well as in contacts, and its value has increased in recent years because of the possibility that BCG vaccination may be a useful prophylactic measure—this procedure converts a negative into a positive lepromin reaction. The authors made a follow-up study of 803 healthy persons on whom a lepromin test had been performed 15 and 20 years earlier in a rural district of Bengal; 123 were not available, and, of the remaining 680 persons, leprosy was detected in 39, or 5.7%. The incidence of the disease was higher (14%) in the lepromin-negative group than in the lepromin-positive group, in which the incidence was only 3.2%. Furthermore, the lesions that developed in the lepromin-negative group were of the more serious lepromatous type.

Prophylaxis of Malaria.—Mitra and Chaudhary (*Bulletin of Calcutta School of Tropical Medicine*, April) have carried out therapeutic trials with a single dose of amodiaquin alone and in combination with primaquine to determine the value of these drugs in preventing malaria. They found that prophylaxis was possible with a single dose repeated at fortnightly intervals. The trial was carried out in a rural area and primaquine was added because of its action on the gametocytes. Two groups of 200 persons in adjacent villages about 35 miles from Calcutta were selected for this trial. One group was given the prophylactic dose using two tablets for adults, one for children, and half a tablet for those below the age of four years. Each tablet contained 150 mg. of amodiaquin and 10 mg. of primaquine. At the end of three months blood smears were negative for parasites in the treated group in contrast to the control group in which the incidence of parasite-positive smears had risen from 4.1 to 8.9%.

Herpes Zoster.—In the *Bulletin of Calcutta School of Tropical Medicine* for April, Chakraborty and Bannerjee reported taking the fluid from vesicles of patients with chickenpox and preparing a filtrate. They gave this filtrate subcutaneously, beginning with doses of 0.1 ml. and increasing gradually to doses of 0.3 ml. daily, or every second day, according to the severity of the disease, to 10 men with herpes zoster. Progressive relief from pain was noted soon after the first injection. The vesicles dried within a week in all patients, and in none did any neuralgia persist after the acute stage had subsided. These results compare favorably with those obtained with the use of herpes zoster tissue filtrates. These results give further evidence of the close relationship between the virus of herpes zoster and that of chickenpox and the possibility that they may be identical.

Filariasis.—Although blood examination for microfilaria is generally carried out at night because of the nocturnal periodicity of the parasites, this is not necessary provided a careful examination of a sufficient amount of blood is made during the day. Chaudhary and Bhaduri (*Bulletin of Calcutta School of Tropical Medicine*, April, 1955) took blood from the finger and the antecubital vein of 68 patients. The venous blood collected during the day was negative for parasites in 18 of the patients, although the same patients had positive findings on examination at night. Buxton has suggested that the diurnal counts would be positive when the nocturnal count was over 40, but the authors could not show any such definite relationship. They conclude that examination of a nocturnal specimen is essential for best results.

New Anthelmintic.—Cardol, a constituent of cashew nut shells, has been studied for its anthelmintic property in human beings, because its action has been already recognized in dogs. Cardol, which is chemically a substituted resorcinol, is a viscid brown liquid having powerful irritant properties when applied to the skin or mucosa. Bhaduri and his co-workers gave gelatin capsules, each containing 6 gm., to adults with various infections. There was no sign of toxic effect or fluctuation in blood pressure after cardol was given. In 16 of 23 patients so treated ascariasis was cured; in 19 of 27 patients ankylostomiasis was cured; and in 3 of 10 patients trichuriasis was cured.

Penicillin G in Anemia.—Bhende and Dixit in the *Journal of Postgraduate Medicine* for July reported on six patients with nutritional megaloblastic anemia who were given crystalline penicillin G by mouth. Penicillin is not a hemopoietic agent, but its influence on the intestinal bacterial flora has been said to affect the synthesis, absorption, or availability of vitamin B_{12} in the intestinal tract. This treatment was completely ineffective in this group of patients. The authors believe that the fact that nutritional megaloblastic anemia is not an entity explains the discrepancy in the results obtained by them and those reported by others.

NORWAY

Botulism.—The omission of botulism from the list of reportable diseases in Norway is excusable in that none of the 43 cases of it recorded in this country proved fatal, but a recent outbreak reported by Dr. Sindre Lunde in the *Journal of the Norwegian Medical Association* shows that, had this disease been reportable, much suffering might have been avoided. The trouble began on June 5, 1954, when the inmates of a school partook of a smoked ham. The gastrointestinal symptoms that followed were so slight and transient that they attracted little attention. On June 8, disurbances of vision set in, but, although the ophthalmologist consulted suspected botulism, the disease not being reportable, no action was taken and the ham was allowed to appear again on the table on June 19. This time there were 33 patients, 4 of whom had to be admitted to the hospital. As on the first occasion the reaction began with the gastrointestinal symptoms, which lasted a day or two. After the second day neurotoxic symptoms developed persisting for weeks and in some patients for months. Involvement of the throat and eyes was indicated by difficulties of swallowing, dryness of mouth and throat, loss of pharyngeal reflexes, blurred vision, and diplopia. Clostridium botulinum type B was isolated in pure culture. The B vitamins and neostigmine, or acetylcholine, were given with good effect, but, in some, the ocular symptoms lasted for two months. There are some curious geographical differences in the behavior of botulism. The reason it is more deadly in the United States than in Norway may be that type A is the more prevalent type in the United States, whereas type B is predominant in Norway. The three important outbreaks observed here were traced to infected hams, whereas the six outbreaks observed in Denmark were traced to mackerel, salmon, and herring. The fluctuations in the incidence of botulism at different times and in different countries are probably more apparent than real, reflecting the degree of botulism-consciousness of the medical profession from time to time. Such consciousness might well be stimulated were the seriousness of botulism to be stressed by its inclusion among the reportable diseases.

Acetazolamide for Glaucoma.—In *Tidsskrift for den norske Lægeforening* for Aug. 15, Dr. T. H. Berg reported on 15 patients given acetazolamide as a supplement to other remedies for glaucoma. Among the five patients with acute glaucoma, there were four in whom the combination of acetazolamide with physostigmine and pilocarpine effected a reduction of the intraocular pressure to normal. Among the five with simple glaucoma, there were three in whom eczema around the eyes prevented the use of the usual miotics. In these patients the intraocular pressure could be reduced pending the advent of a phase suitable for operation. Among the four patients with secondary glaucoma was one whose condition had proved refractory to the usual drugs. An operation had seemed inevitable, but after 17 days of treatment with acetazolamide the pressure had become normal. In several patients a fall of pressure in response to acetazolamide was not maintained for long and it became necessary to increase the dose in order to obtain the desired effect. Four patients responded to the drug with gastrointestinal symptoms, and one became so nauseated that it had to be withheld. Four patients suffered from paresthesia of the limbs, which in one was provoked by a single dose of 250 mg. An attack of renal colic occurred in one patient during this treatment. Berg believes that acetazolamide has not yet displaced the older drugs used to treat glaucoma but that it may be regarded as a useful supplement to them.

SPAIN

Gastric Circulation.—Drs. A. de la Fuente Chaos of the University of Madrid and J. L. Puente Dominguez of Santiago de Compostela studied 300 human stomachs after gastrectomy and at autopsy. In general, the vascular arches of the greater and lesser gastric curvatures give rise to large collateral vessels, which branch off at intervals of about 1 cm. These vessels occupy small areas on the surface of the stomach, give small branches to the serosa, and constitute the most superficial vascular plexus of the stomach. They then perforate the gastric wall and progress into the deeper layers of the stomach. In the antrum the vessels of the serous plexus form direct anastomoses by inosculation in an uninterrupted layer. In the fundus these vessels anastomose in star formation with vessels originating in the submucosa. This leaves large spaces without vascularization between the two layers. Microphotographic examination showed that (1) collateral vessels that branch off at a right angle are predisposed to be transformed into recurrent vessels; (2) the caliber of the veins is much greater than that of the arteries; (3) primary vessels change their direction near the point of their origin when they are ready to perforate the gastric wall; and (4) the purely serous vessels are few and small and are placed in a spiroid arrangement by means of which they are adapted to the physiological and pathological dilatations of the stomach. Most of these vessels follow a transverse course from one curvature to the other. The possible recurrent disposition of the primary branches is of interest in the development of local ischemia and venous stasis. Both conditions are favored by bending the branches, near the point at which they enter the deeper layers. The surgeon should bear in mind that the vascularity of the central portion of the fundus is scanty. This makes it necessary to exercise extreme care during suturing, especially when the circulation is impaired as a result of the presence of edema and fibrosis of the wall. In gastric operations, horizontal rather than vertical sutures should be used to prevent strangulation of the vessels and ischemia.

The structure of the vascular plexus of the muscular coat is the same as that of any vascular plexus along all layers of smooth muscle tissue of the digestive tract. The light arrangement of the vascular plexus facilitates circulation during the constant muscular contraction. The function of the vessels of the muscular coat depend on the tonicity of the coat. The scanty vascularization of the muscular zone may be the cause of the poor functional results seen when the atonic stomach of a patient is operated on. The failure of recuperation of gastric tonicity after gastrectomy, when the operation is performed on patients with marked gastric dilatation and pyloric disease of long duration, seems to indicate incapacity of the muscular coat to recover because of the poor vascularization in this zone. No arteriovenous anastomoses occur in the muscular coat.

The submucosal vascular plexus is the most important source of vascularization of the stomach. Between the muscular layer and the muscularis mucosae, there is a heavy zone of connective tissue in which blood vessels branch off and constantly multiply, thus creating a layer of enormous vascularity. The arteries of the submucosal vascular plexus are arranged in polygonal formation, with an enormous multiplication of closed anastomoses that result in a constant, uniform, and intense vascularization of the zone. These characteristics explain the failure of partial ligation in cases of gastrorrhagia because of the fact that the multiplication of anastomoses interferes with the unilateral closure. The caliber of the veins is three or four times that of the arteries. Venous blood lacunae are formed in some of the large veins. Some of the veins have many vasa vasorum. The stratigraphic arrangements of the vessels, their volume, the multiplicity of their anastomoses, and their passage into the mucosa by means of vertical arborizations show that this richly vascular layer is the stomach's only blood depot. This large vascular plexus maintains hypersecretion of the glandular apparatus, but it may be the cause of the occurrence of grave and even fatal hemorrhages from perforation of venous blood lacunae. Repeated hematemesis and melena is explained by uniformity of the blood supply given by the arterial polygonal formation. Arteriovenous anastomoses exist in this plexus. The vascular plexus of the muscularis mucosae is the seat of most of the arteriovenous anastomoses. The role of the vascular short circuits in the formation and course of gastric ulcer has been proved. Closing and opening of vascular short circuits result in hypoxia or anoxia in certain zones. This facilitates the digestion of tissues by the gastric juice.

Submucosal Plexus.—With certain regional exceptions, the arteries of the submucosal plexus pass obliquely through the muscularis mucosae to reach the mucosa. Here they divide into three or four branches in a spiral arrangement and end in capillaries that form circles about the glands. Changes of caliber of the capillaries play an important role in the formation and course of gastric ulcer through their correlation with the nervous mechanism that regulates stimuli and controls the quantitative and qualitative variations of gastric secretion. Ulcers occur frequently in the poorly vascularized zone between the antrum and the duodenum. The occurrence of the ulcer either in the gastric or the duodenal region gives special characteristics to its clinical evolution, which depends on the degree of vascularity of the involved region. A similar ulcerous predisposition may exist in the lesser curvature where few vascular anastomoses are found. The vessels of the mucosa of the lesser curvature are not branches of the submucosal plexus as is the case with those in other gastric regions. They have an extragastric origin, branching off from the left gastric artery. These branches perforate the gastric wall without forming a submucosal plexus. When they reach the muscularis coat they separate into three or four tortuous branches that anastomose with those nearby. Then they branch off into the mucosal arteries, forming a vascular layer similar to vascular layers observed in other regions except that the diameter of their lumen is very small and they form but few anastomoses. The extragastric origin of the arteries of the lesser curvature gives these zones certain peculiarities. The blood supply depends on local stimulation of the mucosa and on general sympathetic stimulation, which causes vasoconstriction of the main arteries. This is not the case with the blood supply of the mucosal zone of the anterior and posterior walls, the vascular mucosal plexuses of which are regulated by the same stimulation that regulates the submucosal plexuses. The value of this arrangement is appreciated when it is compared with the action of the vagus that causes acute ischemia in the antrum pylori in the lesser curvature. These structures form a circulatory solidarity that suddenly disappears in the duodenal region. Similar vascular changes are caused by emotion and stress.

The vascularity of the cardia, the lower portion of the esophagus, and the gastric fundus is uniform. The left branch of the hepatic artery progresses through the omentum to the anterior and posterior aspects of the abdominal esophagus. The inferior phrenic artery divides into the superior or diaphragmatic, the right or esophagocardial, and the left or tuberosal branches, which reach the thick gastrophrenic ligaments. The large anastomoses of these vessels and the absence of valves in the coronary veins may cause retrograde currents in patients with portal hypertension. Under these circumstances, varices form in the fundus and in the esophagus. The presence of an abundant periadventitial venous plexus and of vasa vasorum in the local vessels is another possible cause of gastric lesions. If thrombosis is the real cause of gastric ulcers, the role of the periadventitial plexus is definite because of the fact that the zones of ischemia in this plexus may produce thrombosis of the underlying vessels.

CORRESPONDENCE

VITAMIN K EMULSION

To the Editor:—In the Oct. 15, 1955, issue of The Journal, page 635, is an article entitled "Treatment of Coronary Thrombosis with Myocardial Infarction," which contains a recommendation for the use of one of our products that is causing us considerable concern. As printed in The Journal, the disturbing statement appears as the first complete sentence on page 638. Speaking of the antidotal use of vitamin K for anticoagulant-induced hemorrhage, a dose of 5 to 10 mg. per kilogram of body weight of "vitamin K emulsion" is given by reference to a single article on this use of the emulsion (vitamin K_1 is clearly meant since it is the only such emulsion domestically available and the article referred to is on "emulsified vitamin K_1"). Such a dose of vitamin K_1 for a man weighing 75 kg. (165.4 lb.) would come to a total of 375 to 750 mg. of Emulsion of Vitamin K_1 given intravenously. This dose is away and beyond anything recommended for the treatment of anticoagulant-induced hemorrhage. Our original dosage recommendations for the emulsion were in the general range of 100 to 150 mg. for emergency use. Since the introduction of Emulsion of Vitamin K_1 a large body of literature has collected on the subject showing a steady trend to a much lower dosage. We have just revised, and had accepted by the Food and Drug Administration, a new text on Emulsion of Mephyton, recommending doses for emergency use usually only up to 50 mg. (Occasionally doses up to 100 mg. may appear necessary and may be advisedly used.) There are two good reasons for not giving excessively large doses of Emulsion of Vitamin K_1. One, that from larger doses prolonged interference with subsequent therapy with prothrombin-depressing drugs occurs; and two, the intravenous use of huge amounts of the emulsion presents a question of safety that has not been adequately investigated. So it is hard to justify the use of up to 750 mg. (15 cc.) of this material as against a usually adequate dosage of up to 50 mg. (1 cc.). We realize that the authors of the article have reported accurately from their reference by Guttas and co-workers (*Blood* 8:276, 1953); however, this single paper, published over two years ago, does not represent the present consensus of most investigators using Emulsion of Vitamin K_1 as an antidote to prothrombin-depressing anticoagulants. The consensus, as mentioned above, is toward relatively low dosage. Furthermore, Guttas and his colleagues in their article recommend far smaller doses of vitamin K_1 in the absence of emergency (even these doses—0.5 to 2.0 mg. per kilogram of bodyweight—are higher than those now considered good practice for nonemergent use). Realizing the importance of optimum dosage and dosage forms, Merck & Company, Inc., will make available tablets of vitamin K_1 so that in nonemergent situations small doses can be given readily and without the need for intravenous administration. Investigators have found that quite small doses of vitamin K_1 by mouth aid in the control of prothrombin levels and lessen the hazard of actual hemorrhage from anticoagulants.

SKIN TESTING FOR PENICILLIN SENSITIVITY

To the Editor:—The report of Berger and Eisen in The Journal, Sept. 17, page 191, "Feasibility of Skin Testing for Penicillin Sensitivity," quite properly emphasizes the shortcomings of this procedure but does not adequately assay the value of the penicillin skin test when it is positive. The association of a strongly positive immediate skin test, read at 15 minutes, with penicillin anaphylaxis has been documented by many authors. Recently B. B. Siegel and co-workers reported positive passive transfer in every 1 of 10 instances of anaphylactic shock, with a high titer of reagins in several, indicative of the presence of a positive immediate direct test. Thus most observers agree that a strongly positive immediate skin test is indicative of anaphylactic sensitivity to penicillin and serves as a warning against its administration. This test is most safely done by the scratch method and only then supplemented by graded intracutaneous tests. Nonetheless false negative tests occur. It is only the positive, not the negative test, that is of clinical value. The delayed positive skin test is more common but of less certain clinical usefulness. First described by Welch and Rostenberg (*J. A. M. A.* 126:10 [Sept. 2] 1944) it was found positive in 5% of adults tested. This incidence among those never before exposed to penicillin (a possibility more certain a decade ago than today) was confirmed by others. Risman and Boger (*J. Allergy* 21:425, 1950) tested over 200 persons in three groups: those not previously exposed to penicillin, those treated but not reacting, and those with a history of reaction. The incidence of the positive delayed test was, in the respective groups, 5, 10, and 55%. These tests were carried out with crystalline penicillins rather than with procaine penicillin, as done by Berger and Eisen. However, there is some indication that the latter likewise elicits a positive reaction, although it may be a less sensitive test material. Berger and Eisen also deviated from the technique employed by previous observers in that they injected only 0.02 cc. instead of the usual 0.1 cc. for this test. Neither the delayed nor the immediate skin test is likely to be positive at the time of or soon after the ordinary delayed type of urticarial reaction. Tests are positive if some level of persistent penicillin sensitivity is established. The immediate reaction becomes highly positive if an anaphylactic level is attained. The delayed test is positive only when either an erythematovesicular reaction has or may occur or when an accelerated (not immediate) clinical reaction is likely. As with the immediate skin test, the absence of a positive delayed skin test should not be interpreted as indicating absence of allergy. Berger and Eisen state their belief that penicillin desensitization "is not feasible." Its feasibility has been documented by at least four independent observers (O'Donovan and Klorfajn, *Lancet* 2:444, 1946; Peck and Siegal, *J. A. M. A.* 134:1546 [Aug. 30] 1947; Alexander, *A. M. A. Arch. Dermat. & Syph.* 68:323 [Sept.] 1953; and Roberts, *A. M. A. Arch. Indust. Hyg.* 8:340 [Oct.] 1953). Several of these cases illustrate not only the recovery of tolerance to the antibiotic in full therapeutic dosage but also the conversion of penicillin skin tests from positive to negative. Limitations of, indications for, and technique of penicillin desensitization are included in my recent review of the problem of antibiotic allergy (*New York J. Med.* 55:2303, 1955).

ESTROGENS AND BLEEDING

To the Editor:—I read in the Oct. 8 issue of The Journal, page 546, the article "Estrogen Given Parenterally to Control Epistaxis and Hemorrhage After Adenoidectomy." The author states that "the purpose of this article is to offer a relatively new approach to these problems." I have been in general practice for the past 25 years and have done a fairly large amount of nose and throat surgery. In the early 1930's, while perusing the literature to obtain information concerning the control of bleeding following tonsillectomy and adenoidectomy, I found that the use of estrogens was advocated for the control of bleeding, and I used them parenterally in patient's who had postoperative hemorrhage. I am glad that the author called attention to the use of estrogens in bleeding, but their use is not new. After practicing medicine for many years, one hears of many new discoveries that are not really new or discoveries.

IS THERE A DOCTOR . . .?

Richard Gordon

Lecturers in medical schools often wonder during their last twenty minutes of class what can be occupying the dozen or so students who are not fiddling with their notebooks, sharpening their pencils, staring encouragingly at the clock, or reading a newspaper under cover of their desks. These pupils are sitting with their chins in their hands and their pens in their mouths, lost in thought. They are, in fact, indulging in the same little daydream, which runs like this:

The student, in his best suit, is walking down Oxford Street on a sunny afternoon, which is suddenly disturbed by the squeal of brakes and a scream. Immediately a crowd gathers. This respectfully divides as he hurries up, pulling out his stethoscope, and announcing "I am a doctor." In the road lies the most beautiful blonde he has ever seen. Behind her stands her mother in hysterics and a distraught taxidriver. "I'll take charge here," says the student crisply. "No fractures," he adds, running his hands professionally over her limbs. "Constable—don't stand there staring, man! Fetch an ambulance. Don't worry, my dear, you're in good care." He visits her daily at the hospital, and during her convalescence they get married. Afterwards they live happily in a large country house, because her father turns out to be unbelievably rich, and she bears him several beautiful children.

Such happy accidents unfortunately never happen. The first one I attended, a week after passing my finals, may have involved a blonde heiress—I never found out. Pushing my way into the crowd I came against a large man in a check overcoat who spun round and shouted "Who the hell d'you think you're shoving, sonny?" "I am a doctor," I explained with dignity. For a second he looked me up and down, assessing my youthful face, my only suit, and the collar that should have been at the wash. "And I'm Madame Butterfly," he said, returning to his savouring of the disaster.

At my next accident I reached the centre of the crowd, where I found a drunken Irishman holding his foot with one hand and trying to fight a lorry driver. As I attempted to minister to him he tried to fight me instead, and I was glad to be hustled away by the police. My third accident occurred in Cornwall. This time I won the esteem of the audience, so much so that a week later I was summoned to give evidence in the local police court. The case was a complicated one, and had to be adjourned several times. Later it developed into a civil action at the local assizes. By then I was beginning to think of giving up my London practice and settling in Truro.

Now I wouldn't even answer an appeal for a doctor in the middle of a West End musical—it would be only one of the stage hands down with his rheumatism again. This attitude is not wholly compatible with the Hippocratic Oath, but it agrees with the forthright gentleman who taught me surgery, Old Blood and Thunder. "Never stop for a street accident, gentlemen," he declared during a lecture on fractures. "It'll land you in the coroner's court quicker than anything. Besides, you'll be spoiling a lot of fun. Do you realize that every street in the country's full of men, women, and Boy Scouts who've got a first-aid certificate and are longing for a chance to slap on a pair of splints in dead earnest? Let them get on with it, gentlemen—they know a damn sight more about pressure points and bandages and black eyes than we do. If ever I'm dragged out of the Thames I'll have a healthy policeman to do artificial respiration, thank you, not some overweight doctor who's soon more asphyxiated than I am. Besides," he added, "you'll never get a fee for it. Remember, gentlemen, that human bones are filled not with red marrow but black ingratitude."

The public nevertheless enjoys seeing a man dashing up with a stethoscope, and the medical profession is never thought of more highly than when it is getting in the way of two trained attendants trying to push a stretcher into an ambulance. For drama, a doctor in a hurry is better than a fire engine and almost as good as a smash-and-grab. This was demonstrated by a fellow-student of mine who enjoyed passing his spare evenings at one of the big Palais de Dance in Tottenham Court Road. The man who shared his digs rang up one night and asked if his friend might be brought to the telephone, adding, for prompter service, that the dancer was a doctor. The management, who recognized free entertainment by instinct, immediately stopped the band and ordered a roll on the drums. The conductor stepped to the microphone and announced solemnly that Dr. Smith was needed urgently on the 'phone. Smith happened to be in the middle of the floor, and was picked out by a red spotlight and he hurried towards the exit through awe-struck couples, who reverently made way. He said he felt disappointed himself when his friend asked where he had put the sausages for supper.

Another student at Edinburgh some years ago was less fortunate. He was riding in a tram down Princes Street one morning shortly after his arrival when it knocked over a pedestrian. The vehicle's first-aid box was produced, and an untidy old gentleman who had been sitting opposite shakily tried to apply a tourniquet. After watching him fumble for some time the student said "Here, old chap, you'd better let me have a go at that. I'm a medical student."

"By all means, young man, if you wish," was the reply. "Though I don't suppose you'll have much more success, because I'm the Professor of Surgery."

THE DOCTOR ON THE SCREEN

HE HAS BEEN IN RELATIVELY VERY FEW FILMS AND FEW OF THEM HAD ANY SIGNIFICANCE

Jack Spears

The doctor has been the central figure in little more than a hundred fiction films in the more than 50 years of filmmaking.

Almost all were box office successes (the most notable turkey was *Sister Kenny*). Stanley Kramer's current *Not as a Stranger* is expected to gross between seven and ten millions.

From an informed, realistic medical viewpoint, however, only a few of these movies had anything of consequence to say.

The doctor got into movies quite early. He appeared in some of George Méliès' curiosities, broadly caricatured of course, but possessed of the air of mystery and superiority doctors have immemorially enjoyed.

The country doctor has been much beloved in movies.[1] One of D. W. Griffith's early Biograph films was devoted to and called *The Country Doctor*. The title was also used for the picture Rupert Julian produced and directed in 1927 for Cecil B. DeMille's short-lived company, and for the picture Henry King directed in 1936 for 20th Century-Fox. These three pictures had different stories. Henry King's was a sentimental account of the birth of the Dionne quintuplets and the role of Dr. Alan Roy Dafoe (played by Jean Hersholt).

The public's love and respect for the country practitioner precluded the intrusion of social values into films about him. This was especially true of the *Dr. Christian* series, a group of medical soap-operas featuring Jean Hersholt. Also true of Will Rogers' homey charms in *Doctor Bull*, a John Ford directed version of James Gould Cozzens' novel, *The Last Adam*, about a New England village medico who cared for all ills—from horse to human. Lew Ayres added considerable stature to the medical profession as a backwoods Pygmalion in *Johnny Belinda*. Bing Crosby and Barry Fitzgerald traded the round collars of *Going My Way?* for the stethoscope of *Welcome Stranger*, more an attempt to capitalize on the success of the earlier film than to deal seriously with medicine.

---

[1] The story that inspired Sir Luke Filder's famous painting was made into a 2-reeler in 1926, entitled, of course, *The Doctor*. Eight years later a 1-reeler song act, also called *The Doctor*, was built around Sir Luke's painting and was touchingly sung by Helen Morgan.

The best country doctor picture was RKO's *A Man to Remember*. Filmed in fifteen days at a cost of only $119,000, this unpretentious B-film proved to be one of the sleepers of 1938. It was Garson Kanin's first directorial effort, and Edward Ellis gave a beautifully low-key performance as a country doctor too dour to be really popular, too kindly to collect his fees, and too conscientious to neglect his professional responsibilities.

The doctor has been very useful as a personality device, different from the common run of men, to spice otherwise routine romantic melodramas. In 1915 one of these was called *The Doctor's Secret*. In 1929 that title was used for a film in which the secret was Ruth Chatterton's attempt to leave her husband and her return to him when her lover is killed.

Doctors provide excellent situations for domestic dramas and light comedies. One of the earliest romantic mellers using a doctor for its main gimmick was *The Doctor and the Woman*, from the Mary Roberts Rinehart novel. It was scripted and directed by Lois Weber, one of Hollywood's very few women directors (cf FIR, Nov., 1950). Strictly geared for laughs were *Every Girl Should Be Married*, *Over the Moon*, *The Doctor Takes a Wife*, and the stupid *No Minor Vices*. As the harried pediatrician in *Every Girl Should Be Married*, Cary Grant set a pattern which was frequently repeated. Fred MacMurray was a likeable baby specialist in *The Lady Is Willing*, as was James Mason (in some curious casting) in *Caught*, a peculiar mixture of comedy and drama.

The doctor-nurse-wife variant of the eternal triangle has been used in such light fare as *Doctor's Women*, *Doctor's Wife*, *Doctor and Nurse*, and *Between Two Women*. The latter, a potboiler of 1937, was scripted by Erich von Stroheim, although his name did not appear in the final credits. The once-great director of *Greed*, according to the publicity, based most of the story on personal observations at the Los Angeles hospital in which his wife had been a patient.

Other domestic dramas with medical overtones included *Doctors' Wives*, an early Frank Borzage talkie; *I Take This Woman*; *I Married a Doctor*; *The Doctor and the Girl*, a Dr. Kildarish mish-mash of medicine, romance, domesticity and sociology; and *Society Doctor*, in which Robert Taylor, as a Park avenue specialist, did little more than prepare his public for his appearance as a dedicated young doctor in *Magnificent Obsession* (1936). That slick soap-opera was re-made last year.

The doctor does not lend himself too well to comedy. He was broadly caricatured by Mack Sennett, and in 1925 by Stan Laurel in a take-off called *Dr. Pyckle and Mr. Pryde*.

One of Harold Lloyd's best vehicles was *Doctor Jack* (1923), a spoof about a breezy young country doctor who believed in auto-suggestion. Doctors delighted in Lloyd's unorthodox prescriptions: excitement for a bored society girl, the visit of a neglectful son to his invalid mother, curing a small boy by telling him the schoolhouse burned down. Stethoscopes became make-believe telephones and temperatures were taken with sugar candy. If Lloyd poked fun at the pompous seriousness of the medical profession, he also showed that much of the art of medicine lies in inducing a sense of optimism and happiness. Many physicians came away from this Lloyd comedy with a quiet desire to be like Doctor Jack.

Very probably the doctor is too staid a figure for comedy. Not so for action pictures, however. *Dr. Jim* (1921) was a rollicking sea story about a doctor who had a selfish wife. Thomas Mitchell gave an excellent performance as the drunken doctor in *Stagecoach*. Johnny Mack Brown was a convincing medico in *Flame of the West*, as was Jeff Chandler in *The Great Sioux Uprising* and Charles Starrett in *The Medico of Painted Springs*. Doctors have also been useful in mysteries. Lionel Atwill solved the crime in *Dr. X* (1932), as did the doctor in *Dr. Broadway* (1942). *Green for Danger* was a very intriguing mystery involving an operating room.

Although a "doctor" is an indispensable character in horror films, most producers designate them as "scientists." Even so, the practicing physician appears frequently in "chillers"—e. g., the oft-made *Dr. Jekyll and Mr. Hyde*, *The Mad Doctor*, and *The Crime of Dr. Crespi*. *Life Returns* was an incredibly bad but very curious film about a practicing physician tampering with the secret of life. Originally produced by Universal in 1934 and considered too bad for release, it was eventually given a few showings through an independent distributor after the director, Eugene Frenke, bought the negative from Universal. More recently it has been making the rounds on television. Onslow Stevens gave a fine performance as the young doctor and the medical detail was quite accurate.

The doctor as psychiatrist is not as new in films as young cinemaddicts think. *The Lunatics* or *Dr. Goudron's System*, based on the André de Lord play, was made in 1914. The psychiatrist was very important in some of the post-War I German successes—notably *The Cabinet of Dr. Caligari* and both of Fritz Lang's *Dr. Mabuse* films, which contained many authentic medical and psychiatric touches.

Private Worlds (1935), the first of the modern psychiatric films, and an interesting excursion into the social problems of mental illness, was perhaps ahead of its time. The psychiatric movie came into its own a decade later with Alfred Hitchcock's *Spellbound*. Basically, *Spellbound* was a typical Hitchcock "chase," and the lesson in psychiatry it gave audiences, though accurately documented, was a mistake. Neither Ingrid Bergman nor Gregory Peck made good psychiatrists, but Michael Chekov, as a kindly Dr. Freud type, gave a realistic portrayal. A dream sequence designed by Salvador Dali was excellent. *Spellbound* was adversely criticized in some psychiatric circles even though it accurately presented psychiatry and psychoanalysis.

Anatole Litvak's *The Snake Pit* was not great cinematic art but it was the first film to show, honestly and thoughtfully, what happens when a person ceases to be an interesting neurotic and is locked in an institution. Litvak's insistence upon realism was very effective. Though socially significant, *The Snake Pit's* accusing and terrifying theme made it unpopular.

The Dark Mirror, with Lew Ayres as a psychiatrist investigating the pathological complexes of twin sisters, was silly but unique. *The Doctor Takes a Wife* treated psychiatry in terms of broad comedy. *The Cobweb*, a slick film with glossy finish, has a competent cast and good direction but does little more than corroborate the old medical saw that you have to be a little mad to be a psychiatrist.

The public health doctor was effectively, if belatedly, lauded in Elia Kazan's *Panic in the Streets*, and, to a lesser degree, in *The Killer That Stalked New York*. The specialist in infantile paralysis got his due in *Young Lovers* and *Interrupted Melody*, as did the medical missionary in *Grand Canary*, the prison doctor in *My Six Convicts*, the obstetrician in *Life Begins*, the brain surgeon in *Dark Victory*, and the plastic surgeon in *A Woman's Face*, *The Scar* (also known as *Hollow Triumph*), and *A Stolen Face*.

The doctor in World War II has received scant attention. Virtually the only picture about him was Cecil B. DeMille's *The Story of Dr. Wassell*. In a sensitive performance Gary Cooper portrayed the small-town Arkansas physician who, as a Navy medical officer, successfully evacuated nine wounded men from Java after the Japanese invasion. DeMille could not resist giving to this simple tale of simple heroism the bright and brassy trappings of a Technicolored superepic. As a result it misfired.

A World War II doctor had a minor role in *Mister Roberts* and in the British-made *Counterblast*. There were aspects of the post-war military medico in *The Men*, in which Everett Sloane gave a fine performance as the doctor. The refugee doctor was depicted in a disappointing version of Erich Maria Remarque's *Arch of Triumph*. The wealth of medical detail in the novel was almost entirely lacking in that hackneyed film, and Charles Boyer was a singularly unconvincing Dr. Ravic.

The nurses of World War II were featured in *So Proudly We Hail* and *Cry Havoc,* two dramas of nurses on Bataan.[2] Nursing has been depicted in many movies, including Biograph's *The Romance of a Trained Nurse; The White Parade; The Nurse's Secret;* and a series of cheap mysteries starring Aline MacMahon (*Patient in Room 18, While the Patient Slept).* Probably the best picture about nurses was George Stevens' *Vigil in the Night* (1940), a somber story about a patient who died because of a nurse's dereliction of duty, with Carole Lombard as a wooden-faced nurse and Brian Aherne as a gloomy doctor.

The woman doctor was first portrayed on the screen by Bessie Barriscale, in a frothy 1921 comedy entitled *Kitty Kelly, M.D.* The lady medico appeared in more serious vein in *Dr. Monica, Private Worlds,* and *Woman Doctor. Girl in White* was the autobiography of Dr. Emily Dunning Barringer, the first woman doctor to intern at New York's Bellevue Hospital. Its semi-documentary style vitiated what could have been a romantic account of interesting medical experiences. Greer Garson essayed the woman doctor most recently in *Strange Lady in Town.* Even her graciousness did not save that melodrama about a woman doctor on the New Mexico frontier.

The medical student, played for comedy in the recent British *Doctor in the House,* has been best depicted in *Miss Susie Slagel's,* in which Lillian Gish was the spinster who kept a boarding house for students at Baltimore's Johns Hopkins Medical School.

The most interesting films about doctors are those in which the background is some aspect of the medical profession itself. *Young Dr. Kildare* began an engaging series of entertaining dramas of the big metropolitan hospital. Doctors were bemused by some of the clinical hi-jinx of Dr. Kildare (Lew Ayres), but audiences were delighted and trooped back for years to see films appallingly alike. When Ayres was bundled off to the Army (he was a conscientious objector), MGM quietly substituted the bobby-sox idol, Van Johnson, in the role of the young intern and continued as before—with equal or greater success. Despite some liberties in the portrayal of hospital life, the *Dr. Kildare* series, and its successor, the *Dr. Gillespie* series, were good for medicine, and did much to counteract the effects of the "exposé" type of film.

Several pictures on medical history were made in the late '30s and early '40s. The best were Warners' *The Story of Louis Pasteur* and *Dr. Ehrlich's Magic Bullet,* both directed by William Dieterle. The former traced the career of the conqueror of anthrax and father of the modern germ theory. Aided by the Academy Award performance of Paul Muni, it was, despite some tinkering with truth, a faithful account of a medical triumph. *Dr. Ehrlich's Magic Bullet* touched on the hitherto eschewed theme—except in cheap exploitation pictures—of syphilis. The story of the discovery of 606, the arsenical compound used to treat syphilis, was tactfully handled (the Hayes office required that the script, by John Huston, reduce references to syphilis by name to twelve). Hollywood has not again ventured into this subject.

Paramount's *The Great Moment* was a confusing, but likeable, comedy-drama of the discovery of ether by a Boston dentist, Dr. W. A. Morton. As originally conceived by Preston Sturges, it essayed a dramatic interpretation. But studio officials were displeased and compelled Sturges to cut nearly three reels. The emasculated result largely consisted of contrived comedy episodes—funny only to those who can enjoy laughter in a context of physical misery. Joel McCrea, Harry Carey and Louis Jean Heydt were convincing doctors.

Other films utilizing medical history are Dieterle's *The White Angel,* the story of Florence Nightingale (with an antiseptic Kay Francis failing miserably in the lead); *Yellow Jack,* an uninspired account of the conquest of yellow fever; and *The Prisoner of Shark Island,* a dull biography of Dr. Samuel A. Mudd, the Maryland farmer-doctor sent to the Dry Tortugas for setting the broken leg of John Wilkes Booth.

Joseph L. Mankiewicz has directed two films about the medical profession: *No Way Out* and *People Will Talk.*

In the latter, an adaptation of Curt Goetz's fine German film, *Dr. Med. Praetorious,* Mankiewicz turned directly to the medical profession for an incisive look at doctors' manners, morals and ethics. Slickly written and directed, it had barbs but was tempered by an understanding of the basic philosophies of medicine. The doctor (Cary Grant) espoused some new ideas of medical care (including abolition of the age-old maxim that hospital patients be awakened at 5:30 a. m. for bath and breakfast). *People Will Talk,* however, failed to be a realistic picture of the medical profession, partly because of its over-sophistication, partly because of a profusion of eccentric characters.

No Way Out was an intolerant attack on racial intolerance in the medical profession and spoiled a story about a young colored intern, responsible for the death of a white patient, and his persecution by a pathological racist, when it proffered force and violence as the Negroes' "way out."

Films attacking the medical profession appeared coincidentally with the world-wide economic depression of the early '30s, although Lon Chaney's *The Penalty* (1920) and *A Blind Bargain* (1922) had hinted at professional incompetence and ethical shortcomings.

Sinclair Lewis' *Arrowsmith* (1931) was the first really serious film about medicine to come out of Hollywood. Sensitively directed by John Ford, and superbly acted by Ronald Colman and Helen Hayes, it touched delicately on some of the professional, economic and ethical problems of the American doctor by depicting the rise of a small-town physician and his conflict over whether to abandon his patients for a career in research.

In MGM's *Men in White* the medical profession experienced its first serious attack. The play, by Sidney Kingsley, presented a vicious picture of life in a metropolitan hospital. Professional incompetence, questionable medical ethics, hospital staff politics, and the implications of illegal abortion, were exploited irresponsibly. The film watered some of this down, but enough remained to constitute a militant attack on the M.D. Cinematically, *Men in White* was talky and slow moving, due largely to the stagy techniques of its director, Richard Boleslawski. It was one of the last films produced by Monta Bell, whose meteoric rise as a silent director (*The Torrent*) was followed by an equally rapid decline.

A Doctor's Diary (1937) was a derisive, savage attack on medical ethics, in which Sidney Blackmer, as a worldly surgeon, neglected a charity case in an emergency to pamper a wealthy patient. *Bedside, Internes Can't Take Money, Once a Doctor,* and *King's Row* also pictured some of the seamier sides of medicine and certain types of medical racketeering. As motion pictures, none was important and only *King's Row,* with its incisive characterization of an incompetent sadistic surgeon, enjoyed wide popularity. Less brutal, and more true to life, was Republic's *Doctors Don't Tell* (1941), a surprisingly good little film expertly directed by Jacques Tourneur.

Cinematically, the best of the "exposés" was MGM's *The Citadel,* produced in Great Britain in 1938. It recounted the story of an earnest young Scottish surgeon (admirably played by Robert Donat), who sets up practice in a poor Welsh mining community. Discouraged by poverty and distrust, he moves to London's stylish Harley street and embarks upon a career of fee-splitting and other hardened medical quackery. He—and medicine—are redeemed at the end when he is read out of the profession by his peers. Except for the contrived climax, *The Citadel* faithfully followed Dr. A. J. Cronin's novel and was perceptively directed by King Vidor.

In the mid-forties American medicine received another stunning blow in *Sister Kenny,* a screen biography of the Australian nurse whose controversial technique for the treatment of poliomyelitis had led to open warfare within medical circles. The film was hysterically partisan and cast organized medicine as a stupid, relentless menace adamant against any medical advance it had not itself developed. The distortions were implied rather than stated, and the one most repeated was that doctors denounced Sister Kenny and rejected her treatment. (In actual fact the Kenny technique was and is widely accepted as a *part* of polio therapy that is most effective when used in conjunction with other medical techniques, but it is not accepted as the whole or only treatment.) The film smothered the fact that Sister Kenny's results were no better than those usually obtained in recoveries and improvements by orthodox methods. Rosalind Russell, a close friend of the real Sister Kenny, and crusader for her cause, played the title role and is said to have badgered RKO Radio, against its wishes, into producing *Sister Kenny*. Dudley Nichols' direction was no better than his confused script.

---

[2] *Nurse Edith Cavell* was a fine screen biography of the World War I British nurse accused of spying in Belgium and executed by the Germans.

As a runaway best-selling novel, Morton Thompson's *Not as a Stranger* shocked many by the viciousness of its attack on American medicine. Translated to the screen by Stanley Kramer, it is a powerful drama and cinematically competent, but the final evaluation of *Not as a Stranger* is yet to be made. It is not simply another "exposé" picture, and it is to Kramer's credit that the film has considerably less venom than the novel. Yet, many patently untrue things in the book have been retained. The characterization of the doctors is less venal, and Kramer has recognized that some doctors are honest and intelligent. *Not as a Stranger* probably presents more of the minutiae of medicine than any preceding film, but this does not compensate for its highly debatable anti-medicine propaganda. Finally, casting Robert Mitchum as the ruthless, insensitive but also idealistic young doctor was an unforgivable mistake.

What do doctors themselves think of the manner in which they have been portrayed on the screen?

The medical profession has resented the distortions in such films as *Men in White, Sister Kenny* and *Not as a Stranger*, and the focusing upon the seamier sides of medicine in *The Citadel*. Nevertheless, most doctors feel the excesses of the "exposé" picture are offset by the tributes of *A Man to Remember, Panic in the Streets* and *The Snake Pit*. The maliciously caricatured doctor (e. g., Frank Ferguson's obstetrician in *Caught*) has been rare.

Hollywood, usually attentive to such things, has tended to be careless about the authenticity of medical atmosphere. Alan Ladd in *And Now—Tomorrow* made doctors chuckle when, to relieve Loretta Young's deafness, he injected her with a self-developed and clinically untried drug. Barry Fitzgerald's supervision of his own appendectomy while under local anesthesia in *Welcome Stranger* was rightly regarded as ridiculous in the extreme. Dr. Kildare constantly amused doctors by his grave snap diagnoses (always right, of course) and the pompous manner in which he imposed them upon the venerable Dr. Gillespie (Lionel Barrymore). The classic was in *Young Dr. Kildare* when Ayres, picked from a line of newly graduated medical students, diagnosed Gillespie's cancer after a dozen top specialists had failed to do so. The Dr. Kildare films were also notorious for impressive but phony medical double-talk.

Doctors were convulsed when Joel McCrea operated on gangster Lloyd Nolan, who had been shot in *Internes Can't Take Money*, with some tools from a nearby bar—including an ice pick, lime juice and a jigger glass. And, of course, saved the day and Nolan.

Many plastic surgeons have watched open-mouthed the antics of their screen counterparts. In *The Stolen Face* Paul Henreid had no difficulty in surgically duplicating the face of his lost love on a disfigured prostitute (Lizabeth Scott played both roles to simplify casting). This fallacy that faces can be identically duplicated has been the gimmick in numerous films. Any plastic surgeon knows it can't be done.

Paul Henreid offended again in *The Scar*. After killing his double, a successful psychiatrist, he not only took over a lucrative psychiatric practice but had no difficulty in fooling his psychiatric colleagues as well. Henreid also destroyed credibility when he took a scalpel and duplicated a scar on his cheek (alas, on the wrong side). Despite these follies, *The Scar* managed to be rather engrossing entertainment.

Most doctors feel Hollywood has yet to produce a truly accurate picture of the medical profession, and they doubt such a film will ever be made. Overdramatizing, and capitalizing on "exposés," have been too successful in the past to be abandoned.

MEDICAL FILM REVIEWS

Blood Grouping: 16 mm., color, sound, showing time 22 minutes. Produced in collaboration with the Group Laboratories, Mile End Hospital, London, England. Procurable on loan from Imperial Chemical Industries (New York) Ltd., Film Library, 488 Madison Ave., New York 22.

This film is intended to show students and house officers some of the techniques used in routine blood grouping in the hospital laboratory. It is divided into the following sections: (1) ABO grouping using the tile method in which reactions of various blood groups are clearly shown; (2) ABO grouping by the tube method; (3) rhesus grouping using saline anti-Rh serum; (4) rhesus grouping using "incomplete" anti-Rh serum and cells suspended in bovine albumin; (5) rhesus grouping using "incomplete" anti-Rh serum diluted in bovine albumin; (6) a "rapid" modification for emergency use only is shown. A number of photomicrographs demonstrate the microscopic examination of the results obtained. This film probably meets the conditions in England much better than those prevailing in this country. There is evidence of economy that in this country would be considered as going too far and as being inconsistent with reliable results. This refers particularly to the use of one pipet for all solutions, including testing serums. It is assumed that rinsing the pipet in distilled water and then saline will get rid of all the serum present. In view of the fact that transfer of a minute amount of serum may lead to trouble, such technique may be subject to question. The same holds true for the use of one glass rod for mixing of the tests on the tile. It is true that wiping off the glass rod ought to remove the cells, but there is a possibility of transfer unless one is extremely careful. Some may criticize the statement that from the observation of weak agglutinations it is concluded that the cells were A$_2$ without further check. It would also be considered bad practice to limit the typing only to tests with known serums, without testing the unknown serums with known type cells. With due consideration to situations prevailing in Great Britain, the film is worthy of presentation to technicians, interns, and medical students.

Gout and Gouty Arthritis: 16 mm., color, sound, showing time 18 minutes. Prepared by John H. Talbott, M.D., Buffalo, and Alexander B Gutman, M.D., New York. Produced in 1954 by Worcester Film Corporation, Worcester, Mass., for and procurable on loan from Sharp & Dohme, Division of Merck & Co., Inc., West Point, Pa.

The purpose of this film is to teach current knowledge on the history, etiology, diagnosis, and treatment of gout and gouty arthritis with particular reference to the use of the uricosuric agent Probenecid. This is an excellent review of the modern treatment of gout. Special emphasis is placed on diagnosis, particularly the use of radioactive isotopes and their role in determining the pathogenesis of this disease. Use of newer drugs for the management of gout is also shown. The film points out that a patient whose condition is properly managed may lead a comfortable life even though not cured. The film is well produced and well organized; photography is excellent. It is recommended for the general practitioner and for students of gout.

Good Health Practices: Part I: 16 mm., color, sound, showing time 10 minutes. Produced in 1953 by and procurable on purchase ($90) from Avis Films, Inc., 904 E. Palm Ave., Burbank, Calif.

The purpose of this film is to instruct primary and elementary grade children in the basic good health practices of proper eating, toilet habits, cleanliness, and rest and sleep. The comparison between an engine's burning fuel and exhausting waste products and the human body's digesting food and eliminating waste is clearly drawn. The film's motivation is in the direction of keeping fit for fun, and the ideas suggested are in general good. However, many of the concepts outlined in connection with practices discussed are misleading, if not incorrect. For example, it suggests that people must regularly go to the bathroom morning and night or oftener. It also advises washing all over daily as an essential health practice. The setting is so elaborate that many children would have difficulty identifying themselves with the situations and subjects. In closing scenes the girl is much too mature for her age. The film needs many revisions to be recommended for classroom use. The color photography is excellent.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Pentolinium and Hexamethonium Combined with Rauwolfia in the Treatment of Hypertension. E. Dennis, R. Ford, R. Herschberger and J. H. Moyer. New England J. Med. **253**:597-600 (Oct. 6) 1955 [Boston].

Of 109 patients with hypertension treated as outpatients, 75 (group 1) who had previously received Rauwolfia serpentina and hexamethonium for three months or more were changed from therapy with Rauwolfia combined with hexamethonium to Rauwolfia combined with pentolinium tartrate (Ansolysen). The remaining 34 patients (group 2) received Rauwolfia combined with pentolinium tartrate from the outset of treatment. Both hexamethonium and pentolinium tartrate were administered by a titration method, i. e., therapy was begun with small doses of the ganglion-blocking agent and then continued with increased doses until an optimal reduction of blood pressure was obtained or side-effects prohibited further increase in dosage. By contrast, Rauwolfia compound was given as a fixed dose of 2 mg. of reserpine, 8 mg. of alseroxylon, or 400 or 500 mg. of whole Rauwolfia root per 24 hours, usually administered in divided doses with meals and at bedtime. Of the 75 patients in the first group, 57 (76%) were responsive to the combined treatment with Rauwolfia and hexamethonium, and 59 (79%) were responsive to the combined treatment with Rauwolfia and pentolinium tartrate. The comparable response rates indicate the similarity of effect between hexamethonium and pentolinium tartrate. The average daily dose of hexamethonium for all patients who were responsive was 2,307 mg., in comparison to an average daily dose of 341 mg. of pentolinium tartrate, suggesting that milligram for milligram pentolinium tartrate is six or seven times more potent than hexamethonium. Of the 34 patients in group 2, 32 (94%) were responsive to the combined treatment with Rauwolfia and pentolinium tartrate. Of the total of 109 patients treated with Rauwolfia and pentolinium tartrate, 91 (83%) responded to this treatment with a reduction of 20 mm. Hg or more in the mean arterial pressure, taken in the upright position; 39 (36%) were normotensive in the upright position. Untoward side-effects, attributable to ganglionic blockade, were similar in frequency but less intense with Rauwolfia combined with pentolinium tartrate than with Rauwolfia combined with hexamethonium.

Drug Therapy (Rauwolfia) of Hypertension: I. Pharmacodynamics of Rauwolfia. J. H. Moyer. A. M. A. Arch. Int. Med. **96**:518-529 (Oct.) 1955 [Chicago].

Reviewing the pharmacodynamics of the administration of Rauwolfia compounds to laboratory animals and to patients with hypertension, the author found that there is no experimental evidence to indicate that Rauwolfia extracts differ qualitatively in their pharmacological activity. They seem to reduce the blood pressure both in animals and in patients with hypertension by central suppression of vasoconstrictor impulses, thus decreasing the outflow of vasoconstrictor impulses over the sympathetic nervous system to the arterioles. The reduction in blood pressure is primarily due to peripheral vasodilatation, since cardiac output is not altered significantly, even though the heart rate usually decreases. The rauwolfia compounds are sedatives that reduce anxiety with a minimum amount of soporific effects. This response is usually lost after two to three months of continuous drug administration, and in a small percentage of patients may actually be replaced by anxiety and insomnia due to the drug. In laboratory animals there is little effect on renal hemodynamics, whereas, in patients with hypertension, the glomerular filtration rate is slightly reduced as the blood pressure decreases following parenteral administration of reserpine, but after prolonged oral administration no consistent effect has been seen.

Drug Therapy (Rauwolfia) of Hypertension: II. A Comparative Study of Different Extracts of Rauwolfia When Each Is Used Alone (Orally) for Therapy of Ambulatory Patients with Hypertension. J. H. Moyer, E. Dennis and R. Ford. A. M. A. Arch. Int. Med. **96**:530-543 (Oct.) 1955 [Chicago].

The authors report comparative studies on Rauwolfia. An attempt is made: (1) to compare the clinical results obtained with single, pure alkaloids of Rauwolfia serpentina (e. g., reserpine and Rescinnamine) and those obtained with preparations containing multiple active alkaloids (e. g., alseroxylon, Roxinil, or whole root) and (2) to determine, if possible, the type of case for which these agents are particularly suited. Studies were made in 346 patients with hypertensive vascular disease. Most of them were treated as outpatients, and they were observed during a control period of from one to three months before treatment was begun. All patients received placebos during the control period. Roxinil was given to 40, alseroxylon to 118, whole root Rauwolfia to 42, reserpine to 62, and Rescinnamine to 84 patients. There was no significant difference, quantitatively or qualitatively, in the hypotensive action of the five products studied. In comparing the potency of the various preparations, the studies indicated that 1 mg. of reserpine is equivalent in hypotensive activity to 250 mg. of crude root, which is lower than the 1:1,000 ratio reported by Wilkins. One milligram of reserpine manifests hypotensive activity equivalent to 4 mg. of alseroxylon. This is consistent with the fact that 4 mg. of alseroxylon contains the active alkaloids extracted from 250 mg. of Rauwolfia serpentina root of average potency. Rescinnamine is slightly less potent than reserpine. All of the Rauwolfia preparations had a slow onset of action. Reserpine appears to be somewhat more rapid than the other preparations. The side-effects of the five agents were qualitatively similar, but quantitatively there were minor differences.

Clinical Aspects of Tumor Formation in the Thorax. W. Unverricht and V. Obrecht. Ärztl. Wchnschr. **10**:869-872 (Sept. 23) 1955 (In German) [Berlin, Germany].

The authors review the records of 100 patients who were either referred to their clinic with a diagnosis of intrathoracic tumor, or in whom such a diagnosis was considered or made in the course of the clinical examination. Sixty-six of the 100 patients were referred to the clinic with the diagnosis of intrathoracic tumor, and in 48 of these this diagnosis was corroborated. Of the 34 patients who were referred with a diagnosis other than tumor, 26 were found to have tumor. The fact that some of these patients had been treated for weeks, months, or even years and that in many the tumor was already inoperable when a diagnosis was finally made emphasizes that greater efforts must be made to establish the diagnosis of bronchial carcinoma earlier. Particularly in patients between the ages of 50 and 60 any disease of the respiratory organs should be regarded as possible tumor until this diagnosis has been definitely ruled out. The presence of tubercle bacilli in the sputum does not necessarily speak against a tumor, since, on the one hand, tumor may coexist with tuberculosis and, on the other hand, the sputum may temporarily contain tubercle bacilli without activation of a pulmonary tuberculosis. An exploratory thoracotomy should

---

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1946 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

be done early in all cases in which the diagnosis cannot be established, for when a tumor becomes roentgenologically demonstrable it may already be in an inoperable stage. Although the results of surgical treatment are still rather modest, it is the only treatment that is at all promising for patients with pulmonary tumor. The authors obtained no decisive effects with irradiation; on the contrary such treatment usually caused undesirable complications. Treatment with so-called cancer serums and with biological methods likewise has proved disappointing.

Examination of Gastric Acidity Without Stomach Tube: Determination of Quinine Excretion in Urine After Administration of Insoluble Quinine Compound. J. W. Boersma. Nederl. tijdschr. geneesk. 99:2564-2568 (Aug. 27) 1955 (In Dutch) [Haarlem, Netherlands].

The author calls attention to the tubeless method of ascertaining gastric acidity, which was described by Segal and associates in 1950 and in 1953. He reports his own experience with this method in several groups of patients. Since orally ingested quinine can be detected in the urine for about a week, the patient should not receive compounds containing quinine for this number of days before the test. After fasting since 8 p. m., the patient is given the following morning a subcutaneous injection of histamine, in order to stimulate gastric secretion. The urine, which the patient voids 30 minutes later, serves as a control. Then the patient is given the insoluble quinine compound in water (now generally quinine carbonate). The urine that the patient voids two hours later is examined for the total quinine contents. The author reports the quantities of quinine detected in the urine of several groups of patients. The outcome of the quinine carbonate test was compared with acidity determinations on fractional gastric aspiration. The quinine test was found to be reliable for differentiating between achlorhydria and subnormal and normal secretion of free hydrochloric acid. The quinine test is less laborious and less unpleasant for the patient than fractional gastric examination.

Chronic Nonspecific Granulomatous Inflammation of the Stomach, Duodenum and Intestine. A. Richman, H. D. Zeifer, A. Winkelstein and others. Gastroenterology 29:358-369 (Sept.) 1955 [Baltimore].

Nonspecific granulomatous inflammation of the ileum, as described by Crohn and called regional ileitis, was at first considered to be limited to the terminal ileum. It is now apparent that this disease may involve the gastrointestinal tract from esophagus to rectum. The suggestion has been made that granulomatous inflammations represent a reaction of the gastrointestinal tract to stress and that each segment of the tract may participate. The literature reports 14 cases in which the duodenum and/or the stomach were involved, with or without more distal disease. These 14 cases plus 3 new ones, whose histories are presented, are analyzed. The 17 patients ranged in age from 9 to 62 years. On the basis of the clinical patterns, the patients are classified into four groups. In group 1, distal disease was followed by proximal disease; in group 2, proximal disease was followed by distal disease; in group 3, proximal and distal disease were discovered simultaneously; and in group 4, disease was limited proximally to the stomach or duodenum with or without jejunal involvement. This last category was the most common variant and included one patient with esophageal involvement in addition to disease in the stomach and duodenum. In this patient the disease took a fulminating course with duodenal perforations, hemorrhage, and fatal outcome. There were four fatalities in the 17 patients, two of which occurred shortly after resection of the diseased stomach or duodenum. The two other patients died of recurrent disease one and two years after surgery respectively. The three patients whose histories are reported here have done well so far. Although gastric and duodenal disease develops in relatively few patients with regional enteritis, the appearance of gastric symptoms should suggest the presence of disease in the stomach and duodenum. In all three of the cases observed by the authors, surgical treatment became necessary, but they hope that, as their experience increases, some patients will respond to nonsurgical measures.

Frequency of Diabetes in Acute and Chronic Pancreatitis and in Carcinoma of Pancreas. R. Llamas and A. Vélez Molina. Rev. invest. clín. 7:143-156 (April-June) 1955 (In Spanish) [Mexico, D.F., Mexico].

Sixty-three patients with disease of the pancreas were observed in the Hospital de Enfermedades de la Nutrición of Mexico City. In the group of five patients with acute pancreatitis, the diagnosis was made by a laparotomy in three cases. The values for blood amylase were high in all five patients. One patient had diabetes and four had biliary lithiasis. In the group of 21 patients with chronic pancreatitis, the diagnosis was made at operation or at autopsy in 17 patients. Eleven patients had diabetes mellitus, and eight of these had pancreatic calcifications. There was a diabetic glucose tolerance curve in one patient. In the group of 37 patients with pancreatic carcinoma, the diagnosis was made at laparotomy or at autopsy in all cases. Ten patients had diabetes mellitus. In 11 cases the carcinoma was located in the head of the pancreas. Chronic pancreatitis or diffuse fibrosis was observed in nine of these patients, seven of whom had diabetes mellitus. The findings suggest that fibrosis and chronic pancreatitis may play an important etiological role in the development of diabetes mellitus complicating pancreatic carcinoma.

Whereto Tuberculosis? The First Seven Years of the Antimicrobial Era, 1947-1953. G. J. Drolet and A. M. Lowell. Am. Rev. Tuberc. 72:419-452 (Oct.) 1955 [New York].

Streptomycin, aminosalicylic acid, and isoniazid, though discovered and brought into use only a few years ago, have already given life to hundreds of thousands of tuberculous patients throughout the world. Streptomycin, the first of the antituberculous drugs, became generally available primarily in 1947; aminosalicylic acid, which was developed abroad, came to hand here in 1949; and finally, in 1952, the general use of isoniazid became possible. The treatment of tuberculosis before 1947, when the chemotherapeutic era began, largely depended on bed rest and collapse therapy, and the case fatality rates had shown but little improvement for more than 20 years. The next seven years, on the other hand, saw the most rapid decline ever recorded in deaths from tuberculosis, with a fall in the death rate ranging from 53% in France to 83% in Iceland, as shown by official statistics obtained from 15 countries and the commonwealth of Puerto Rico. Morbidity reports show a lesser rate of reduction, with a case rate that is now 20% lower, in five of these countries and the commonwealth of Puerto Rico, but actually higher than before in Eire and possibly also in Australia. Care must be used in interpreting the Irish statistics, because the higher level of tuberculosis case rates and mortality is due partly to the fact that Irish industrialization and modern development are of comparatively recent origin and partly to the fact that many of the Irish workers who were employed in England during World War II had marked susceptibility to tuberculosis and later carried the disease home with them. The rate of progress, however, though starting from a higher level of prevalence, has been similar to that in Scotland and England, with a reduction of 12% in the case rate and 68% in the death rate between 1947 and 1953. The third and last index that may be used with reference to the prevalence of tuberculosis is the extent of infection as revealed by tuberculin tests. The results obtained by such tests in various parts of the world show that boys and girls at age 15 still react positively at rates ranging from 12% in Lebanon or 18% in rural Eire to 85% in Polish cities. The favorable condition now prevailing in the United States may be judged by the fact that 95% of some 150,000 recruits in the United States Navy and Marine Corps reacted negatively to the tuberculin test in 1954. These advances in the fight against tuberculosis must not be taken to mean that the disease is no longer a major health problem. The number of new cases reported in the United States, the British Isles, France, and Germany in 1953 alone totalled 340,416 and, if the number of old and previously known cases (conservatively estimated at three times the new cases) is added to these, it will be seen that there were more than one million known cases of active tuberculosis in just those four countries in that year.

The Prophylaxis of Penicillin Reactions with Chlorprophenpyridamine Maleate Injection 100 Mg. per Cubic Centimeter. D. B. Frankel and R. E. Stutsman. Ann. Allergy **13**:563-570 (Sept.-Oct.) 1955 [St. Paul].

The incidence of penicillin reactions varies from 2 to 16%. Dermatitis, urticaria, and serum sickness are among the most frequent, but the most severe is anaphylaxis, and the greatest danger lies in death from shock. In the United States there are 200 anaphylactoid reactions due to penicillin every year, and many of these reactions result in death—usually within 5 minutes after injection. While there is no certain way of predicting when severe or fatal reactions are likely to occur, a method has been found that greatly reduces their incidence and permits the administration of penicillin to individuals known to be sensitive to it. This method is the administration of an antihistamine in conjunction with penicillin. It was first described by Simon in 1952, who used it in over 5,000 cases and reduced the incidence of penicillin reactions to 0.72%. The authors gave 540 injections of penicillin combined with chlorprophenpyridamine maleate to patients without previous signs of sensitivity to penicillin. The dose of chlorprophenpyridamine maleate was 20 mg. or 0.2 cc., withdrawn from a vial containing 100 mg. of the antihistamine in each cubic centimeter. After the antihistamine was drawn into the syringe, 600,000 units of aqueous penicillin were added. The syringe was rotated to insure adequate mixture, and the injection made in the usual manner. No reactions occurred in these 540 injections. There were likewise no reactions in 29 injections of 600,000 units of penicillin with 40 mg. chlorprophenpyridamine maleate in 15 known reactors or in 5 injections of 600,000 units of penicillin with 40 mg. of chlorprophenpyridamine maleate in 4 indefinite reactors. No side-actions attributable to the antihistamine were noted. Three definite and three indefinite reactions occurred among 583 injections of penicillin alone in patients not known to be sensitive to penicillin, an incidence of 1.03%. The severe reactions were angioedema and serum sickness. These favorable results have led to the suggestion that chlorprophenpyridamine maleate solution be administered with each dose of penicillin for the prophylaxis of sensitivity reactions.

Phlebitis: A Study of 748 Cases at the Boston City Hospital. J. J. Byrne. New England J. Med. **253**:579-586 (Oct. 6) 1955 [Boston].

Of 748 patients with phlebitis admitted to the Boston City Hospital over the past decade, 621 (83%) were over 40 years of age. The mortality increased with age. No seasonal variation could be found. The conditions predisposing to phlebitis in order of frequency were cardiac disease, postoperative state, trauma, infection, varicose veins, childbirth, hemiplegia, cancer, and miscellaneous conditions. No predisposing disease whatsoever apparently occurred in 49 patients (65%); the cause of phlebitis in this group of patients with spontaneous or idiopathic phlebitis could be related to minor trauma or effort. Fatal pulmonary emboli occurred frequently in phlebothrombosis and thrombophlebitis. It is misleading to consider these two conditions as separate entities, because, although its manifestations may vary, all phlebitis is essentially the same process. The mortality rate with the various methods of treatment was as follows: of 347 patients who received conservative treatment, 128 (37%) died; 369 patients were given surgical treatment, with 8 deaths (2.1%); 32 patients were treated with anticoagulants and 9 died (29%). Of 144 patients with fatal pulmonary emboli resulting from preexisting phlebitis, the first embolus was fatal in 122 (84%). Phlebitis, therefore, should be actively treated before embolization occurs. Bilateral division of the superficial femoral veins should be performed as soon as the diagnosis of phlebitis is made. If there are thigh signs (edema, tenderness, and evidence of trauma), the common femoral vein should be divided. When clots are adherent or difficult to extract, further treatment (anticoagulants or ligation of the vena cava) is indicated. The postphlebitic syndrome is associated with the severity of the phlebitis rather than the type of treatment.

Indefinitely Prolonged Chemotherapy for Tuberculosis: An Appeal. A. S. Dooneief, K. E. Hite and R. G. Bloch. A. M. A. Arch. Int. Med. **96**:470-477 (Oct.) 1955 [Chicago].

Pulmonary tuberculosis may relapse even if there have been no symptoms or signs of activity for years. After abrupt reactivation, the disease may become quiescent again. The incidence of reactivation or relapse prior to chemotherapy ranged from 24% to more than 50% in patients followed for more than 20 years after arrest of the disease. There are increasing indications that antimicrobial therapy for short periods of time does not prevent late relapse after chemotherapy has been terminated. Even after surgical excision of all visible lesions, active disease may become evident in other parts of the lungs or the bronchial tree. Reliable prediction of which patients will remain well after termination of treatment is difficult because of lack of reliable criteria for inactivity of residual lesions. The authors found that, of a consecutive series of 172 patients, in whom chemotherapy was continued indefinitely after discharge from the hospital, 98.3% showed no relapse after 12 to 45 months of drug treatment. Drug intoxication was never severe enough to necessitate cessation of treatment. With the aid of placebos, the symptoms of streptomycin intoxication were demonstrated to be due, in part at least, to psychic factors. There was no correlation between the duration of treatment with streptomycin and the occurrence of streptomycin intoxication. Prolonged therapy with various combinations of streptomycin, aminosalicylic acid, and isoniazid proved practicable, relatively devoid of serious toxic reaction, and generally acceptable to properly indoctrinated patients. Since the optimal duration of drug treatment is not presently known, the authors believe that chemotherapy under close supervision should be prolonged indefinitely except in the presence of threatening side-effects or until a reliable guide to termination of chemotherapy becomes available.

Pathogenesis of Anemia in Tuberculosis. P. Miescher, O. Gsell and B. Fust. Schweiz. med. Wchnschr. **85**:917-919 (Sept. 20) 1955 (In German) [Basel, Switzerland].

Patients with a disseminated tuberculosis frequently have anemia. The pathogenesis of this form of anemia is usually regarded as being due to a disturbance in the hematopoiesis. This disturbance is believed to be caused by an iron deficiency in the bone marrow, which in turn has been brought on by the tuberculosis and by the toxic action of the infection on the hematopoietic organs. The authors raised the question whether an increased destruction of erythrocytes might be an additional factor in the pathogenesis of this anemia. This possibility interested them, because disseminated tuberculosis is accompanied by a considerable reactive hypertrophy of the reticulohistiocytic apparatus, that is, of those tissues that play the most important part in the catabolism of the cellular elements of the blood. They investigated the life span of homologous erythrocytes that had been tagged with radioactive chromate in healthy and in tuberculous guinea pigs. The tuberculous guinea pigs had been injected intraperitoneally with tubercle bacilli of human type. The life span of the erythrocytes was significantly shorter in the tuberculous than in the normal guinea pigs, and the authors deduce from this observation that the accelerated breakdown of erythrocytes plays a part in the pathogenesis of the anemia that accompanies tuberculosis. The fact that the number of reticulocytes was increased in the tuberculous animals seems to indicate that the bone marrow strives to compensate for the increased breakdown by an augmented erythropoiesis. The observation that the reticulohistiocytic system hypertrophies in experimental tuberculosis and that the granulopectic effect of this system is increased justifies the assumption that the augmented destruction of erythrocytes is caused by an increase in the cytoclastic activity of the reticulohistiocytic system.

Corticotrophin and Cortisone in the Treatment of Scleroderma. M. M. Zion, B. Goldberg and M. M. Suzman. Quart. J. Med. **24**:215-227 (July) 1955 [Oxford, England].

This report deals with the use of cortisone and corticotropin in 14 patients with scleroderma. The ages ranged from 23 to 70 years, and there was an equal number of men and women. In nine patients scleroderma was associated with peripheral vascular disturbances of the Raynaud type; in the remaining five there were no vasospastic phenomena. In one of the former and one of the latter group, the sclerodermatous changes were confined to the hands, but, in the remainder, there was more generalized involvement of the skin. Six patients had evidence of visceral involvement. The duration of the symptoms of scleroderma prior to the onset of treatment with corticotropin or cortisone varied from three months to 12 years, and seven patients had previously received other forms of therapy. In all the patients, the diagnosis of scleroderma was confirmed by histological examination of a biopsy specimen of skin, and the following investigations were made prior to treatment and repeated at intervals during therapy: radiography of the chest, esophagus, gastrointestinal tract, skeleton, and soft tissues of the limbs; electrocardiography; blood counts and estimations of the erythrocyte sedimentation rate; serum-protein estimations; several liver function tests; and the differential sheep-cell agglutination test. From the results obtained in these 14 patients, it appears that the response of scleroderma to cortisone or corticotropin varies in degree from striking benefit to no effect. Four patients obtained moderate to marked improvement; in one of these there was clinical and histological reversal to normal. Nine patients obtained slight improvement; one patient obtained no improvement. In the patients who showed marked or moderate improvement, the disease before treatment had existed less than six months. The best results were obtained in patients who had no peripheral vascular disturbance. When treatment was temporarily discontinued, it proved impossible to maintain the improvement. Treatment has been continued for periods up to two and a half years and is being continued longer in patients who have improved, in the hope that progression of the disease may be prevented.

First Observations on the Action of Yeasts in Leukemias. G. Protti. Tumori 41:273-288 (May-June) 1955 (In Italian) [Milan, Italy].

The author's in vitro studies on blood cells of patients with leukemia indicated that myelocytes and lymphocytes undergo marked alterations (cytolysis) when they are placed in contact with strains of yeast. The normal blood elements are not altered, however. These results induced him to administer yeasts by the intravenous route to patients with leukemia. A 33-year-old man with chronic myeloid leukemia received 60 mcg. of yeast (Rhodotorula rubra and others) daily after he had been given P^{32} for 14 months. His white blood cell count was 190,000 per cubic millimeter and his spleen was enormous. After nine days, the spleen was decreased by 5 cm. but the white blood cell count had reached a peak of 260,000 per cubic millimeter; four months later it was 60,000. The patient continued to improve; he regained appetite and weight (7 kg. [15.4 lb.] in the first month of therapy) and energy; his abdomen became normal; there was a further decrease in the size of the spleen; and the pain in the bones that had rendered him unable to walk disappeared. A state of well-being, such as he had not experienced for years, lasted for several weeks. Suddenly, about four months after the start of therapy, the patient complained of a shooting lumbar pain to the left side (it was probably of infarct origin); his condition deteriorated rapidly; and he died from generalized sepsis about one month later. Yeast therapy with Cryptococcus albidus and other strains in daily doses of 60 mcg. was given to a 51-year-old man with lymphatic leukemia who had been receiving cortisone but who no longer responded to the hormone. His condition improved; he gained appetite and weight (3 kg. [6.6 lb.] in two months); the spleen and liver became smaller; and the subcutaneous lymphomas became tender and decreased to about one-half their pretreatment size. This therapy was also given to a 61-year-old man with lymphatic leukemia who had received P^{32} with good effects for five years but who no longer responded to it. The minimum daily dose he could tolerate was 2 mcg. A dose of 200 mcg. over a three-month period influenced favorably his general condition and the size of the spleen. The results were superior to those brought about by P^{32} therapy. At the time of writing, improvement was still present in the last two patients. The intravenous administration of yeasts had no effect on the condition of five patients with acute monocytic leukemia and one with subacute leukemia. The mechanism of action of yeasts on neoplastic cells is not known. The fact that they affect only neoplastic cells suggests the hypothesis that they must act on a certain substance that is present in such cells only. The nature of this substance is being investigated.

The Use of Myleran in the Treatment of Chronic Myelocytic Leukemia. A. Haut, S. J. Altman, G. E. Cartwright and M. M. Wintrobe. A. M. A. Arch. Int. Med. 96:451-462 (Oct.) 1955 [Chicago].

The sulfonic acid ester, Myleran (1:4-dimethanesulfonyloxybutane), which was introduced for the treatment of chronic myelocytic leukemia, appeared to be so promising that the authors decided to publish a full account of their own experience with it. Since November, 1952, they used Myleran in the treatment of 16 consecutive cases of chronic myelocytic leukemia. Eleven patients had received no previous therapy; five had been treated earlier with x-rays, nitrogen mustard, triethylene melamine, or radioactive phosphorus. The period of observation since Myleran was first prescribed is more than two years in six cases and more than one year in three other cases. Myleran was administered to 16 patients for a total of 40 courses of treatment. To date, 16 first courses of treatment, as well as 10 second, 6 third, 5 fourth, 1 fifth, and 1 sixth course have been completed. Symptomatic improvement, normalization of the blood findings, and reduction or even disappearance of splenomegaly was achieved when the drug was administered in daily oral doses of from 4 to 6 mg. Remissions continue in some patients for 6 to 12 months. The duration of therapy depends upon the individual response and generally can be expected to be about 40 to 90 days, the longest periods being required in patients with the highest initial leukocyte counts. Weekly to triweekly examinations of the patient and his blood suffice to guide the therapy and, in most cases, to avoid the complications of thrombocytopenia and pancytopenia, which are considered to be the result of excessive dosage.

Thyroid Function Following Hypophysectomy in Man. M. C. Li, J. E. Rall, J. P. MacLean and others. J. Clin. Endocrinol. 15:1228-1238 (Oct.) 1955 [Springfield, Ill.].

This report deals with the effect of hypophysectomy in 35 cases of metastatic cancer. The operation was performed by a transfrontal approach in most of the cases. Completeness of hypophysectomy was evaluated on the basis of (1) disappearance of urinary gonadotropin, (2) occurrence of adrenal crisis upon withdrawal of cortisone, and (3) postmortem examination, when possible. On the basis of these criteria, 28 of the 35 patients were considered to have had complete hypophysectomies and 7, partial hypophysectomies. The changes in the thyroid function with which this study is concerned were well correlated with the foregoing criteria. Within four weeks after total hypophysectomy, values for serum protein-bound iodine and thyroidal I^{131} uptake fell to myxedema levels. Clinical hypothyroidism developed within four to eight weeks after total hypophysectomy in 26 of the 28 patients. The serum protein-bound iodine level and the thyroidal uptake of I^{131} either fell transiently or did not change in the patients with incomplete hypophysectomy. The thyroid was examined histologically in six cases; atrophy with fibrosis was observed in two, and a slight decrease in the height of the follicular epithelial cells was observed in the other four cases.

SURGERY

An Evaluation of the Treatment of Cancer of the Breast at the University of Edinburgh (Scotland), Under the Direction of Dr. Robert McWhirter. L. V. Ackerman. Cancer 8:883-887 (Sept.-Oct.) 1955 [Philadelphia].

Of 1,882 patients with presumed carcinoma of the breast who were treated by McWhirter with simple mastectomy followed by irradiation therapy at the Royal Infirmary of the University of Edinburgh, Scotland, between 1941 and 1947, 786 were living at the fifth year after treatment. Ackerman studied the clinical records and the pathological specimens of 719 of these patients and reached the following conclusions. Thirteen of these patients did not have cancer. Most of the erroneous diagnoses were made in patients with intraductal papilloma. This degree of error, however, will not appreciably change the end-results. The evaluation of the end-results obtained with McWhirter's therapy was complicated by the fact that at least 220 patients received immediate ovarian sterilization after the simple mastectomy, regardless of the stage of the disease or the age of the patient. Therefore, this group cannot be compared with a group treated purely by surgery. The evaluation was further complicated by the fact that excision of involved lymph nodes, diethylstilbestrol therapy, or testosterone therapy was used whenever there was manifest persistence of the disease. Such treatment could have modified survival time. Of the 719 patients, 555 had cancer in the operable stages 1 and 2, and in 90 of these there was local persistence of the disease, a persistence rate of 16%, which is higher than in properly selected operable cases. The incidence of local persistence in the group of patients who died before the fifth year is not known. McWhirter did not demonstrate histological proof of sterilization of carcinoma in lymph nodes; in fact, involved nodes removed after irradiation therapy appeared unaffected in several instances. There was considerable morbidity from McWhirter's irradiation therapy, and 47 patients had severe changes that necessitated amputation of the arm in 3. It must be stressed that, although a number of patients survived five or more years after therapy was begun, 203 died after five or more years, an additional 44 are in a dying state, and still more will die of cancer. McWhirter feels that when a surgeon dissects the axilla he spreads cancer, but McWhirter did not present objective evidence as to the necessity for simple mastectomy. In fact, simple mastectomy may well spread cancer because the surgeon is cutting through tumor tissue. In patients properly selected for radical mastectomy, the trained surgeon only rarely enters the field of cancer in the breast and/or axilla, and the chance of spread is reduced to a minimum. These facts suggest that McWhirter has not put in jeopardy the well-planned radical mastectomy for the patient with operable cancer of the breast. The author believes that, if patients are properly selected for radical mastectomy and operated on by the trained surgeon, this method of treatment must yield, in this group, the greatest number of permanently cured patients.

Malignant Melanoma: Clinical and Pathologic Analysis of 93 Cases: Is Prophylactic Lymph Node Dissection Indicated? R. H. Lund and M. Ihnen. Surgery 38:652-659 (Oct.) 1955 [St. Louis].

The authors state that at their hospital they performed regional lymph node dissections in malignant melanoma only when the clinical impression indicated involvement by metastatic tumor. This study is based on experience gained in treating 93 patients with malignant melanoma of the skin. Factors found to influence the prognosis included the size, the palpability of the regional lymph nodes, the depth of invasion, and the location of the melanoma. Tumors smaller than 2 cm. in diameter were associated with greater longevity than were the larger lesions. A clinical impression of metastases to the regional lymph nodes was nearly always correct and was associated with an extremely poor prognosis. Patients with tumors restricted to the very superficial dermis had a much higher survival rate than those with deeper invasion. Those with melanomas of the head and neck and upper extremities had higher survival rates than those with melanomas of the trunk and lower extremities. Sex, age, and degree of pleomorphism were found to have no influence on the prognosis. The five-year survival rate after wide local excision alone was 38.9%. Twenty-seven patients in this series, in whom nodal metastasis was definitely proved, were subjected to regional node dissections; they had a five-year survival rate of 14.8%. The authors feel that, while this analysis cannot supply a definite answer to the question of advisability of prophylactic dissection of the regional lymph nodes, there is suggestive evidence that earlier dissection of the lymph nodes might have been beneficial. They are of the opinion that prophylactic dissections are indicated if the regional lymph nodes are in predictable and accessible areas.

Surgical Parotitis, A Vanishing Disease. J. R. Robinson. Surgery 38:703-707 (Oct.) 1955 [St. Louis].

This is a review of 32 cases of acute parotitis developing after surgical procedures at Barnes Hospital, St. Louis, from 1921 through 1952. The pathogenesis of this disease is still obscure. There are four possible portals through which bacteria may gain entry into the gland: (1) the lymphatics; (2) the blood stream; (3) the parotid duct; and (4) direct extension from contiguous tissues. The dry mouth appears to be an associated, if not a causative, factor; saliva does not flow properly. Saliva contains mucin, which has a bacteriostatic effect. Presumably, when it ceases to flow, the organisms of the mouth are able to ascend the duct. In order to test the contention that parotitis is a vanishing disease, this series of 32 cases was divided into time periods, corresponding to those in which distinct changes in postoperative surgical management were made. Period 1 includes the years 1921 through 1927; it is the control for the other groups. The second group includes the years 1928 through 1937 and represents a period when much attention was being paid to aseptic intestinal anastomoses, fluid balance, and intestinal decompression by intubation during gastrointestinal surgical procedures. During this era the mortality rates attending colonic and gastric operations were greatly reduced. The third period represents the "sulfa" era and includes the years 1938 through 1942. During this time the sulfonamide drugs were used extensively to treat infection and to prepare the gastrointestinal tract. The fourth period, 1943 through 1952, is the antibiotic era. This decade started with the introduction of penicillin during 1943. During the first of the four periods, eight cases of surgical parotitis occurred in 21,735 admissions, that is, the incidence was 3.68 per 1,000. During the other three periods the incidences were 3.34, 1.82, and 0.17 per 1,000. These figures indicate that surgical parotitis has practically disappeared as a morbid and lethal postoperative complication. The mortality from this entity began to fall before the advent of antibiotics, such as sulfonamides and penicillin, while the incidence did not decline until they were introduced. The mortality from the disease was definitely lowered by x-ray therapy.

The Latissimus Dorsi Syndrome. R. J. Dittrich. Ohio M. J. 51:973-975 (Oct.) 1955 [Columbus, Ohio].

A symptom complex characterized by pain in the upper portion of the body, and designated as "latissimus dorsi syndrome," is described in four men between the ages of 26 and 62 years. The mechanism is one of referred pain and referred tenderness from a primary source, or trigger point, to other somatic structures that are innervated by the same spinal segmental nerves as those in which the impulses arise. In this disorder, the noxious stimuli originate from an irritation of portions of the aponeurosis of the latissimus dorsi muscle in the midlumbar region over the lateral portion of the sacrospinalis muscle. The vulnerability of this site is due to the anatomic arrangement of attachment of a portion of this muscle to the lumbodorsal fascia. Diagnosis of a mechanism of this nature is relatively simple. It may be suspected in any painful condition that is located in the sclerotomes of the sixth, seventh, and eighth cervical nerves from which the latissimus dorsi muscle receives its nerve supply, and it is not explainable by local pathological disorders. Tenderness over the lateral portion of the sacrospinalis muscle at the level of the second or third lumbar vertebra makes the diagnosis more certain. The sensitivity at this site may be so trivial that comparison with the normal side of the body becomes necessary. The final step in arriving at the diagnosis is local anesthetization of the site of origin of the pain, noting the response to this procedure. If, with this procedure, complete or substantial relief is obtained, as it was in all four of the author's patients, it may be concluded that afferent stimulation at this site induces referred pain to upper portions of the body, and surgical correction is indicated. This was performed in three of the four patients and consisted of resection of a narrow strip of the aponeurosis of the latissimus dorsi in the lumbar region above the level of the irritation. Relief from pain was prompt, and there was no recurrence during a period of observation of from 3 to 13 months. In the fourth patient surgical correction was advised but not accepted.

Intrasplenic Pressure Measurements in the Evaluation of the Results of Porta-Caval Anastomosis. M. Atkinson, S. Sherlock and M. D. Turner. Gastroenterology **29**:370-376 (Sept.) 1955 [Baltimore].

Advances in the surgical treatment of portal hypertension have accentuated the need for accurate methods of assessment of results. With regard to intrasplenic pressure measurements, the authors point out that the tip of the needle introduced into the spleen will probably lie in the splenic pulp, which is in free communication with the splenic venules. Therefore, intrasplenic pressure is closely related to the portal venous pressure measured directly or by occluding a hepatic vein. The intrasplenic pressure is slightly higher than the portal venous pressure, as would be expected from the direction of the flow in the portal system. In patients without portal hypertension, the intrasplenic pressure was found to be 3 to 17 mm. Hg, with a mean of 10 mm. Hg. A statistically significant linear correlation between the intrasplenic pressure and the estimated portal venous pressure was observed in 24 patients. The intrasplenic pressure exceeded the estimated portal venous pressure by 2 to 6 mm. Hg; the higher the pressure the greater this difference. The authors describe intrasplenic pressure measurements in seven patients in whom a portacaval anastomosis had been made for the treatment of bleeding from gastroesophageal varices. Six of the seven had portal cirrhosis, and the seventh had occlusion of the portal vein by intrahepatic scar tissue. Five of the patients showed a significant fall in the intrasplenic pressure to normal and near normal levels, and there was other evidence that the anastomosis was functioning well. In the sixth patient, ascites developed after the shunt operation, and the intrasplenic pressure showed an abrupt rise; investigation revealed that the shunt was blocked. The seventh patient showed no postoperative change in the intrasplenic pressure, hematemesis recurred, and portal venography confirmed that the anastomosis was occluded. Pressure measurements made by puncture of esophageal varices at esophagoscopy have been used to ascertain portal venous pressure; however, after portacaval anastomosis, esophageal varices may become collapsed or reduced in size, making this method impracticable. Intrasplenic pressure measurement provides a much simpler means of determining the portal venous pressure.

Annular Pancreas: Its Roentgen Diagnosis and Report of a Case Preoperatively Diagnosed and Successfully Treated Surgically. H. S. Berlin and J. Taylor. Gastroenterology **29**:439-445 (Sept.) 1955 [Baltimore].

In connection with a case report of annular pancreas, the sixth one to date that has been diagnosed correctly before operation, the authors review the normal development of the pancreas and the possible embryonic "mistakes" resulting in annular pancreas. The patient, a 36-year-old man, had a history of indigestion, consisting of periumbilical pain, abdominal distention, and belching shortly following meals. There were also complaints of epigastric pain of six years' duration that radiated to both flanks and was unrelated to meals. Six weeks prior to his first hospitalization, his abdominal symptoms became aggravated and were accompanied by nausea and vomiting. The patient admitted a heavy alcoholic intake, taking several highballs daily and consuming a fifth of liquor over the week-end. Physical examination revealed moderate distention and tenderness in the upper abdomen, particularly at the midline. Laboratory studies disclosed elevation of the lipase and amylase contents of the serum. The serum calcium and inorganic phosphate were also considerably increased. A diagnosis of mild pancreatitis was made, and, on a regimen of a low-fat diet, antispasmodics and antacids, the symptoms subsided rapidly. He was discharged with instructions to maintain a low-fat diet. Roentgenograms made during this hospitalization showed a pressure defect in the second portion of the duodenum, on the basis of which the radiologist suggested the presence of an annular pancreas. Recurrence of symptoms some months later led to repeated roentgenologic examinations, which again revealed duodenal narrowing that was interpreted as being due to annular pancreas. Later an exploratory laparotomy confirmed the presence of an annular pancreas. A simple bypassing procedure effected complete relief of the patient's complaints without morbidity or recurrence of symptoms during the 16-month period that has elapsed since the gastroenterostomy. The authors feel that the simple bypass is the procedure of choice in the treatment of duodenal obstruction due to annular pancreas. If this patient had not been a heavy drinker, it is possible that the annular pancreas would have remained asymptomatic and undiagnosed. Of the approximately 75 cases recorded in the literature, only 5 have been correctly diagnosed before operation.

Accessory Intrapleural Ectopic Liver Lobe. D. Rodríguez-Pérez. Bol. Asoc. méd. Puerto Rico **47**:353-356 (Sept.) 1955 (In Spanish) [Santurce, Puerto Rico].

A case of intrapleural accessory ectopic liver lobe in a girl 15 years old is reported. This is the first case of this condition in human beings reported in the world literature. The patient, a school girl, had a routine x-ray examination of the chest. A mass in the subdiaphragmatic area in the lower region of the right side of the chest was observed. The patient was otherwise normal. A second x-ray examination of the chest confirmed the previous report. The mass was located in the lower lung field, laterally and posteriorly. Exploration of the chest revealed the mass to be free from adhesions. Its vascular pedicle was doubly ligated, cut, and removed. At the pedicle, a portal vein 1 cm. in diameter and a bile duct 3 mm. in diameter were well distinguished. The arterial supply of the accessory structure was maintained by a very small artery. Histological examination of the removed specimen revealed an ectopic liver lobe. The patient made an uneventful recovery. She was discharged one week after the operation. The lung reexpanded well and the wound healed "per primam."

Hemolytic Accident During Transfusion Due to hr' (c) Factor. O. Yahn, C. da Silva Lacaz and O. Mellone. Rev. hosp. clin. **10**:197-200 (May-June) 1955 (In Portuguese) [São Paulo, Brazil].

A man had received many blood transfusions in the past from several donors. He belonged to the O Rh-positive blood group. Further transfusions with blood of O Rh-negative donors caused acute reactions. It was observed from immunohematological tests that the reactions of the patient were due to his sensitivity exclusively to the hr' (c) factor. The antibody acted in saline and albumin mediums. The results of the Coombs' indirect and Morton and Pickles' tests gave positive results for all samples of blood containing the hr' (c) factor. It was observed, also, that anti-hr' (anti-c) serum reacted strongly against erythrocytes containing a "double dose" of the hr' (c) factor, whereas the reaction was weak when the blood used in the test contained a "single dose" of the same factor. This is the first case of transfusional accident due to the hr' (c) factor observed in the Hospital das Clínicas of São Paulo. The authors emphasize the danger of possible sensitization reactions caused by agglutinogens other than the Rh. Before blood transfusion to patients who have had transfusions in the past, it is advisable to make cross matching observations. O Rh-negative donors of the cde/cde subtype should not be considered as "ideal" donors. They should be used only for transfusions given to homologous receptors.

Use of Hyaluronidase in Rapid Hypodermoclysis. E. Otaiza M. and F. Muñoz T. Rev. brasil. cir. **29**:501-510 (June) 1955 (In Spanish) [Rio de Janeiro, Brazil].

One of the uses of hyaluronidase in surgery is for administration of rapid hypodermoclysis. The authors used a preparation ("Kinadena") that contains 10 Schering units corresponding to each 0.5 mg. of hyaluronidase. Seventy patients who had recently had an operation were given one or two hypodermoclyses, making a total of 100 hypodermoclyses administered to the whole group. The authors conclude that the proper dose of hyaluronidase in hypodermoclysis varies between 10 and 15 Schering units per liter of a solution, given at a rate of 90 drops a minute. In the cases observed by the author, the absorption time of hypodermoclysis of saline solution containing hyaluronidase was 125% more rapid than in the controls who were given subcutaneous infusions without hyalurodinase. The absorption time for dextrose solution with hyaluronidase was 20% more rapid than in the controls. There was neither intolerance nor unpleasant reaction to the substance, with the exception of very moderate pain and a sensation of local distention of the tissues in 19 patients and acute pain in 6. Hyaluronidase is contraindicated in cancer, acute infections, and circulatory collapse. It may favor propagation of metastases, spread of an acute infection or aggravate shock and collapse.

An Analysis of Pulmonary Resection in 513 Cases of Tuberculosis. F. H. Cole and F. H. Alley. Surg. Gynec. & Obst. **101:**413-417 (Oct.) 1955 [Chicago].

From December, 1948, to August, 1953, a total of 513 pulmonary resections for tuberculosis were performed at the West Tennessee Tuberculosis Hospital in Memphis. The periods of postoperative observation range from one to five and a half years. The period of this study includes years of great change in the therapy of tuberculosis, with a rapid decline in the frequency of collapse therapy, an increase in excision, and a great improvement in the antimicrobial drugs. Pneumonectomy decreased from 36% in 1949 to 5% in the last 100 operations. Lobectomy and lobe-plus-segmental resection remained fairly constant, but segmental excision increased from 2.1% in 1950 to 41% in 1954. These changes reflect more efficacious drug therapy and also the fact that the early years included many retreatment cases and failures from other therapeutic measures. Bronchostenosis dictated many of the early pneumonectomies, while it is uncommon today. A satisfactory result was obtained in 85%; in 8% the effect was doubtful and in 7%, definitely poor. The total death rate from tuberculosis and surgery was 5%. Since the middle of 1952, results have been decidedly better than before. This improvement coincides with the arrival at operation of patients who had completed long-term chemotherapy, the majority requiring only the resection of residual lesions. Another important factor in the improvement of the results is the avoidance of surgical complications by careful dissections, meticulous hemostasis, accurate replacement of lost blood, and individual attention to tube drainage. The eventual fate of a patient is more adversely affected by surgical complications than by any other single factor. Since July, 1952, good results have been obtained in over 90% of patients operated on. In this period, in which 340 resections were done, only one patient died of surgical complications six months after his operation.

Lymphoma of the Stomach and Intestine. J. F. P. Skrimshire. Quart. J. Med. **24:**203-214 (July) 1955 [Oxford, England].

The cases described comprise 18 patients seen at St. Thomas's Hospital between October, 1948, and September, 1953, four cases from the hospital records, and 2 patients seen at other hospitals. During the five years 1948 to 1953, lymphomas formed 3% of all primary malignant tumors of the stomach seen at St. Thomas's Hospital, and 50% of those in the small intestine. Men were affected more than twice as often as women, and, while gastric lymphomas generally occurred after 40 years of age, those in the intestine occurred also in younger patients, three of the patients reported here being children. The symptoms of gastrointestinal lymphomas are sudden in onset in some patients because of perforation, obstruction, or hemorrhage. In the present series, 20% of the patients had perforations. Recognition of the growth is difficult on clinical examination. The most suggestive features are the tendencies for the growths to be multiple and to produce extensive infiltrations. These characteristics may be recognized radiologically, gastroscopically, or at operation. Histological recognition of the nature of the growths is important because of their sensitivity to irradiation. The course of the disease is usually short, half the patients dying within a year of the diagnosis. Postmortem examinations frequently show very extensive local spread of growth throughout the peritoneal cavity and absent or inconspicuous distant foci of growth. Approximately 10% of all patients, and a greater proportion of those with gastric lymphomas, survive for more than five years. The prognosis is difficult to evaluate.

Gastric Mucosa Within the Oesophagus. K. N. Morris. Australian & New Zealand J. Surg. **25:**24-30 (Aug.) 1955 [Melbourne, Australia].

Ulcers that possess all of the features of peptic ulcer of the stomach occur in the esophagus, and strictures of the esophagus can occur high in the thorax with a length of apparently normal esophagus between the stomach and the level of the stenosis. Investigation of these patients has shown that the lower part of the esophagus is lined with typical gastric mucosa. Peptic ulcers are situated in this area of gastric mucosa, and they may be the site of massive bleeding, penetrate into the mediastinum, perforate into the pleural cavity, or stenose to produce esophageal obstruction. Allison designated this condition as "esophagus lined with gastric mucous membrane." The author reports on seven patients with this disorder who were observed at the Alfred Hospital in Melbourne. The average age of these patients was 65 years. Their clinical histories varied from a few months to 30 years. There was an associated hiatus hernia in three. At operation, it was often difficult to locate the site of esophageal obstruction, as the external appearances of the esophagus and stomach were relatively normal. The correct mode of treatment is still a matter of debate. In two of the early cases observed at the author's hospital, esophagogastrectomy with esophagogastric anastomosis was done in the belief that carcinoma of the esophagus existed, and the result in both instances was satisfactory. Because of this experience, it was decided to attempt a more restricted procedure, and in two patients the stricture was excised locally, and the two cut ends of the esophagus were anastomosed. This is an easy operation that only takes about one-third of the time necessary to do an esophagogastrectomy with esophagojejunal anastomosis. These patients have been followed for 12 months but so far have had no symptoms suggestive of esophagitis. When one divides the esophagus, it is usual to carry out a vagotomy at the same time because of the intimate relationship of the vagus nerves to the esophagus. It is possible that this may have some bearing on the fact that these patients have remained free of esophagitis.

Immediate and Long-Term Results of Surgical Treatment of Portal Hypertension. F. G. Uglov. Vyestnik khir. **75:**22-33 (May) 1955 (In Russian) [Moscow, U. S. S. R.].

Patients with severe portal hypertension treated by conservative methods often die from coma, gastric hemorrhage, thrombosis, or other causes. The most rational treatment of the condition is the establishment of a portacaval anastomosis. Excellent long-term results have also been obtained with the splenorenal and the mesenterocaval anastomoses. Patients with poor liver function and ascites requiring frequent incision and drainage do not tolerate surgical intervention well and must be extremely carefully prepared for operation. The essential feature of preparation of patients with hemorrhage is repeated blood transfusion, whereas in those with ascites it is the parenteral administration of protein in the form of blood or nonspecific serums. Both before and after operation, patients require heparin therapy for the prophylaxis of thrombosis. Patients with cirrhosis of the liver must maintain a strict diet even after operation; they need a large quantity of protein. Of 14 patients treated by radical operation, 11 are living from one-half to two and one-half years after the intervention. Of 10 patients treated conservatively, 9 died during the first two months.

Segmental Peridural Injection of Hydrocortone in Painful Syndrome Caused by Prolapsed Disk. G. Zappalà. Policlinico (sez. prat.) **62:**1229-1231 (Sept. 12) 1955 (In Italian) [Rome, Italy].

The injection of Hydrocortone directly into the tissue of a prolapsed disk is capable of controlling the painful syndrome caused by this condition. This suggests a rapid and direct contact of the hormone with the prolapsed disk and mainly with the compressed roots. This is best achieved by injecting the Hydrocortone (a 3 cc. dose) into the peridural space exactly at the site of the prolapsed disk. The results of this method are good, in that pain (local as well as radiating) and with it antalgic positions (scoliosis) disappear quickly and walking becomes normal. The author has used this method during the last few months, and a report on the favorable results obtained is in progress. Only late results will tell, however, whether this therapy brings about definitive results or whether it is symptomatic only. The advantages of this method, especially for patients who have become toxicomaniacs or those who refuse orthopedic or surgical treatment, are evident. Before a patient with a prolapsed disk is submitted to surgery, the author thinks it advisable to resort to this method. If the segmental peridural injection is carried out well, the pain will disappear, and thus the injection can also serve as a valuable diagnostic test. Acute crises of a prolapsed disk of long standing can also be benefited by this method of treatment.

A Skin Bank for Postmortem Homografts. J. B. Brown, M. P. Fryer and T. J. Zaydon. Surg. Gynec. & Obst. 101:401-412 (Oct.) 1955 [Chicago].

In patients with extensive skin losses, biological dressings in the form of homografts often prove lifesaving. In the past it has been necessary at times to call on a number of donors to supply the needs of one badly burned patient. This involved considerable expense for anesthetics, also time loss, postoperative wound care, and discomfort. It is now possible to take large amounts of skin from a single donor after death and either use it immediately or set it aside for later use in a skin bank. Homografts will "take" and survive for from 2 to 12 weeks, but, although they are eventually lost, closing the wounds with homografts diminishes the loss of fluids, proteins, and electrolytes; there is respite from pain and frequent dressings; infection is diminished; the fibroplastic response in the wound is reduced; a mechanical barrier to trauma is established; and there is a stimulus for the patient's own epithelization so that healing has progressed considerably by the time the homograft is absorbed. There is always a remarkable improvement in the patient's general condition, so that he is prepared for the application of permanent autografts from his own body. Homografts may even be applied repeatedly in successive "crops," after preceding grafts have been absorbed, until autografts can be removed from the patient himself. Adequate sources of skin for homografting would be available if permission were granted by patients before death or by their relatives for postmortem removal of skin grafts. The patient should be free from malignant disease or from transmissible disease or dyscrasia. The relatives might be shown the need for skin on photographs of severely burned patients, and they can be told that there will be no apparent deformity to the skin of the donor and also that only areas covered by clothing, such as the trunk and thighs, are used. It is best to remove the skin as soon after death as possible. In the event of any delay, the body should be kept refrigerated. Viable grafts thus can be obtained after 24 hours' delay, and even up to several days, as final death of skin does not occur at the same time as the cessation of circulation. The postmortem skin grafts are best removed in the operating room, where the skin is prepared with ether and alcohol and sterile drapes. Long sheets of thin split-skin grafts are removed. As these grafts are not permanent, thickness is not necessary. Simple refrigerator banking, low temperature banking, and lyophilization are discussed. The authors advise preservation and storage of skin for use in emergencies and in disasters. There are still many problems to be worked out, acquainting the public with the great need for postmortem grafts for seriously injured patients being one of the most important.

Metabolic Response to Total Adrenalectomy and Hypophysectomy. A. S. Mason. Lancet 2:632-636 (Sept. 24) 1955 [London, England].

Studies were made on the metabolism of eight women with carcinoma of the breast. Metastases were present in seven patients. Two patients were subjected to total hypophysectomy, one to total adrenalectomy, and five to total adrenalectomy and oophorectomy. Corticotropin was administered intramuscularly every six hours to patients undergoing hypophysectomy, and cortisone was injected intramuscularly twice daily to patients undergoing adrenalectomy. The results obtained with this substitution therapy in the first two patients made it obvious that, in order to observe the body's metabolic changes in response to trauma under conditions of constant hormone dosage, it was essential to start the hormone treatment several days before removal of the endogenous source of hormone and to keep the dosage constant throughout the study. Therefore, in six patients the hormone administration was started from two to four days before operation. It was found that corticotropin, in doses of 60 mg. daily, was adequate therapy for total hypophysectomy, and cortisone, in doses of 80 mg. daily, for total adrenalectomy. A dosage of 60 mg. of cortisone daily was also used, but it seemed to be suboptimal. With adequate hormonal substitution therapy, the metabolic response after these operations is similar to that seen after operations on patients with intact adrenals. The results are consistent with the hypothesis that the adrenal cortex plays a permissive role in metabolism and indicate that postoperative metabolic changes do not depend solely on changes in adrenal cortical activity.

NEUROLOGY & PSYCHIATRY

Psychological Changes Associated with Giant Pituitary Neoplasms. J. C. White and S. Cobb. A. M. A. Arch. Neurol. & Psychiat. 74:383-395 (Oct.) 1955 [Chicago].

Among 600 articles dealing with pituitary adenomas and craniopharyngiomas, only 13 were primarily concerned with the psychological changes that these lesions may produce if they expand upward to an unusual size. The authors cite five of their own cases. All but one of these patients have undergone psychiatric investigation. Four of these five patients had adenoma (three chromophobe and one chromophile), and one had a craniopharyngioma. As these tumors expand above the diaphragma sellae and compress the walls of the third ventricle or the frontal lobes of the brain, the mental changes consist of dullness progressing to somnolence and apathy, with difficulty in concentration. There may also be loss of memory, leading to confusion and sometimes confabulation. When aroused, the patient may be irritable, aggressive, and active. Poor judgment is common, and delusions and hallucinations may occur. These signs indicate that there has been a large suprasellar extension of the growth, either forward, between the frontal lobes, or upward and backward, into the third ventricle. With distention of the latter, hydrocephalus may occur from blockage of the outflow of fluid from the lateral ventricle. With extension upward and backward, the amnestic-confabulatory syndrome with somnolence is to be expected. In contrast, when the tumor separates and compresses the frontal lobes, it is likely to produce a syndrome similar to that seen after an extensive bilateral lobotomy. Convulsive seizures may also supervene, especially when extension is forward between the frontal lobes or laterally into a temporal lobe. These signs indicate a giant parasellar extension. The chances for improvement are poor for mental symptoms, for visual recovery, or for relief of headache, regardless of whether treatment is by irradiation or surgery. Ultimately, with further growth of the neoplasm, there is a progressive deterioration to a vegetative state, with increasing drowsiness and finally coma and death. Before a chromophobe adenoma is treated by irradiation, the degree of suprasellar extension should be visualized by pneumoencephalography. All the adenomas with suprasellar extension should be followed by repeated air studies and operated on before the tumor reaches a prohibitive size.

Latent and Benign Meningeal Reactions in Primary Tuberculosis in Children. H. Bour, Mrs. Hébert-Jouas and J.-C. Ducomet. Semaine hôp. Paris 31:3017-3024 (Oct. 2) 1955 (In French) [Paris, France].

A group of 1,409 children with primary tuberculosis was cared for in a preventorium in Brévannes, France, over a four-year period. Twelve of them showed meningeal reactions that were benign, transitory, and spontaneously curable. The percentage of such reactions in this group (0.85%) is undoubtedly less than that among tuberculous children generally, since patients admitted to the preventorium have spent an average of three months in other hospitals, where such reactions may easily have been overlooked. These benign reactions were not detected clinically but manifested themselves as an increase in the number of cells in the cerebrospinal fluid of 22 cells on the average. These were principally lymphocytes. Differential diagnosis of discrete meningeal reactions is important, since some may be early symptoms of tuberculous meningitis, while others are simply the benign occurrences described and do not need to be treated with antibiotics. It is possible that the benign reactions are of viral or allergic origin, occurring because the meninges have been rendered susceptible by the tuberculous process.

Results of Surgical Therapy for Focal Epileptic Seizures. W. Penfield and K. Paine. Canad. M. A. J. **73**:515-531 (Oct. 1) 1955 [Toronto, Canada].

This study is concerned with the results of cortical excision in 234 patients with epileptic seizures, who were treated during the six year period from 1945 to 1950, inclusive. The follow-up was continued at least to the end of 1951, so that there is a minimum follow-up of one year and a maximum of seven years. None of the patients included in this review had intracranial tumor. A total of 268 operations was performed on the 234 patients, some undergoing two or more operations. Cortical excisions were done in 219 patients, while in the remaining 15 patients the exploration proved negative. On the basis of the therapeutic results obtained, the patients were classified into one of five groups. Those with no seizures since the operation were placed into group 4, those with only one attack a year into group 3, those with up to six seizures a year into group 2, those in whom number and intensity of attacks was somewhat decreased into group 1, and those who showed no improvement or were worse into group 0. The number of patients in groups 4 and 3, the successful cases, accounted for 45% of the 203 patients who could be adequately followed up; the number in group 3, the good results, accounted for 20%; and groups 1 and 0, the failures, accounted for 35%. With regard to the social and economic adjustment of the patients, it was found that before operation 79 of 203 patients were fully employed despite their seizures. The threat of losing their employment induced some of these patients to request surgical treatment. Five of these are not employed at present. On the other hand, 51 not previously employed are now on a full-time work or educational schedule. Thirty-eight patients were out of work, but possibly employable, when last heard from. The authors feel that, for three-fourths of the patients, the operation has proved of real benefit. Epileptogenic cortex is harmful in its general influence on brain function. Successful removal may result in better intellectual performance and more normal behavior as well as in freedom from seizures. The operation involves risks. There were four deaths and visual field defects or aphasia in some of the patients; but, in spite of these dangers, the surgical treatment of focal epilepsy is now established as a legitimate form of therapy.

Poliomyelitis Antibodies in Human Gamma Globulin. E. M. Opton, D. Nagaki and J. L. Melnick. J. Immunol. **75**:178-185 (Sept.) 1955 [Baltimore].

Gamma globulin has found use as a prophylactic agent against poliomyelitis, but, at the time of the controlled field tests, titration of neutralizing antibodies against the three types of poliomyelitis virus had been reported only for a single lot of this material, because the intact monkey was then needed for the determination of two of the three types of antibodies. With the advent of tissue culture techniques, the picture has changed. The studies reported here were made with these techniques. Sixty-five samples of human gamma globulin, representative of the materials used for poliomyelitis prophylaxis in the United States during the summer and fall of 1953 and 1954, and two samples of Japanese origin were assayed for poliomyelitis neutralizing antibodies by means of tissue culture neutralization tests. Using a fixed challenge of 100 tissue culture doses of virus and varying dilutions of gamma globulin, the average titers for antibodies against virus types 1, 2, and 3 were 1:1,130, 1:1,060, and 1:770, using data provided by both cytopathogenic and colorimetric tests. Gamma globulin preparations derived from human placentas had as much poliomyelitis neutralizing antibody as the best preparations made from pooled plasma. Comparison of untreated human plasma pools and the gamma globulins derived from them demonstrated that poliomyelitis antibodies were concentrated in this fraction. However, a sample of beta globulin and a sample of gamma globulin, both prepared from the same human plasma, showed neutralizing antibody levels of the same order of magnitude.

Neurotropic Actions of Vitamin B_{12} in Large Doses: Experimental Studies. U. Becattini and A. Testi. Policlinico (sez. med.) **62**:220-225 (Aug.) 1955 (In Italian) [Rome, Italy].

Experiments were made on rats to study the effects of large doses of vitamin B_{12} on shock induced by Metrazol. The vitamin was given to one group of animals six and one-half hours and to another group one-half hour before the administration of Metrazol. The time that elapsed between the administration of this preparation and the onset of the shock in the rats that were given the vitamin was much longer than that in the controls that had not received the vitamin, and during this time the prodromal symptoms of shock were not observed. The duration of the shock was markedly decreased; the manifestations were less marked; there was no muscle relaxation; and the rats' condition was restored to normal in a few seconds. A dose of 2.5 mg. of vitamin B_{12} per kilogram of body weight seemed to saturate the rats; slightly larger doses did not have a greater influence on the shock; and with smaller doses the effects on it were less evident. The authors cannot give a satisfactory interpretation of these results; the mode of action of vitamin B_{12} on Metrazol-induced shock remains obscure. Studies are in progress to determine whether this vitamin has a protective action with regard to other substances that act on the central nervous system.

Progressive Muscular Dystrophy: Effect of Hormonal Treatment. J. A. Taselaar. Nederl. tijdschr. geneesk. **99**:2496-2499 (Aug. 20) 1955 (In Dutch) [Haarlem, Netherlands].

The author mentions four different forms of progressive muscular dystrophy, the excretion of pathological quantities of creatine and creatinine being common to all these forms. The author reviews the creatine and creatinine metabolism under normal and patholgical conditions and the treatment of progressive muscular dystrophy. He found that the administration of vitamin B_{12} or of di-isopropyl fluorophosphate produces no improvement in patients with progressive muscular dystrophy. Prolonged treatment with testosterone derivatives, particularly with testosterone-propylpropionate, however, produced favorable results in 20 male patients with progressive muscular dystrophy. It was also found that creatine and creatinine secretion in the urine is not a reliable indicator of therapeutic efficacy; only physical examination and information supplied by the patient reveal the effect of hormone therapy.

GYNECOLOGY & OBSTETRICS

Noninvasive Malignancy of the Vulva: Program for Management. C. G. Collins, J. Kushner, G. N. Lewis and R. Lapointe. Obst. & Gynec. **6**:339-346 (Oct.) 1955 [New York].

The authors report on 93 women between the ages of 20 and 90 years with malignancy of the vulva. Fifty-seven were less than 60 years old and 16 of these were between the ages of 30 and 40. Twenty-seven women had associated venereal disease. The high incidence of associated venereal disease in the younger age group may have been a causative factor in the early development of malignancy of the vulva. Pruritus vulvæ, ulcer, tumor, and bloody discharge were the symptoms by far the most frequently noted, and they were the same in invasive and noninvasive lesions. Nine patients, in whom the malignant process was limited to the epithelium and in whom no evidence of invasion could be found in multiple sections from biopsy material and complete vulva, were considered as cases of noninvasive malignancy of the vulva. They were managed by complete (radical) vulvectomy, consisting of wide resection of the vulva and including all of the labia, clitoris, and as much of the skin of thigh and abdomen or mucous membrane of the vagina as necessary. No other therapy was utilized. Three of the nine patients were followed up for more than five years and none for less than 22 months. In none of the nine patients has there been a recurrence. These results prove that the authors' contention that noninvasive carcinoma of the vulva, so diagnosed by multiple microscopic sections, can be treated by radical vulvectomy and that resection of the regional nodes is not necessary. In all cases of suspected malignancy of the vulva, venereal disease survey is as imperative as is biopsy.

Krukenberg Tumors: Diagnostic Problem. A. W. Diddle. Cancer 8:1026-1034 (Sept.-Oct.) 1955 [Philadelphia].

Each of the author's nine patients with metastatic ovarian carcinoma had been seen by two to five physicians before the correct diagnosis was suspected. Usually, it was undetermined until either laparotomy or autopsy was performed. This situation prompted the author to summarize previous discussions concerning 664 cases of Krukenberg neoplasms collected from world literature, with special reference to the diagnostic problem they presented. The term "Krukenberg tumor" as used by the author includes only those carcinomas of the ovary arising from the gastrointestinal tract and those signet-ring-cell carcinomas primary in the ovary itself. The author's study showed that when the triad of persistent, sometimes almost negligible, dyspepsia, anorexia with epigastric discomfort, and firm adnexal tumor is found, particularly in a woman of reproductive age, metastatic ovarian carcinoma, with primary neoplasm of the gastrointestinal tract, should be included in the differential diagnosis. Repeated roentgenographic studies of the gastrointestinal tract, gastroscopy, occasionally bimanual examination under anesthesia, exploratory laparotomy, or a combination of these procedures is required to confirm the diagnosis and to ascertain the origin of the neoplasm. Roentgenographic study, if depended on alone, may be misleading. Occasionally, the primary site may not be found until a careful postmortem examination is made. The diagnosis of metastatic ovarian carcinoma of Krukenberg carries a grave immediate prognosis. This holds true even though a relatively small primary lesion of the gastrointestinal tract may be removed with the metastatic ovarian cancer. This poor prognosis probably rests on the fact that, by the time the ovaries are involved, spread in the lymphatic system is extensive. The metastatic ovarian carcinoma of Krukenberg represents an advanced terminal phase of a neoplastic disease arising in the gastrointestinal tract. At this stage, treatment is usually only palliative. When peritoneal implants are widespread, it is apparent that radical operations, as presently done, are of questionable value. Under this circumstance radical removal appears useless and justifiable only to relieve pressure symptoms, the occasional exception being those tumors arising in the large intestine. An extensive bibliography comprising 177 papers is appended.

Fetal Mortality in Essential Hypertension. R. Landesman, E. Holze and L. Scherr. Obst. & Gynec. 6:354-365 (Oct.) 1955 [New York].

Of 735 pregnant women with essential hypertension admitted to the New York Lying-In Hospital between 1943 and 1953, 591 had mild hypertension and 144 had severe hypertension. Of the 591 with mild hypertension, 161 had superimposed toxemia of pregnancy and 430 did not. Of the 144 patients with severe hypertension, 30 had superimposed toxemia and 114 did not. The total abortion rate was 9.2%. Among the women with mild hypertension without superimposed toxemia, the abortion rate was 4.4%, and among those with superimposed toxemia it was 1.9%. Among the women with severe hypertension without superimposed toxemia, the abortion rate was 36% (half of it due to therapeutic intervention, and the other half spontaneous), and, among those with superimposed toxemia, it was 3.3%. The abortion rate among the women with superimposed toxemia would necessarily be low, as superimposed toxemia usually commences after the 24th week. The fetal loss, excluding abortions, among the women with mild hypertension without superimposed toxemia was 1.7%, while among those with superimposed toxemia it was 16.4%. Among the women with severe hypertension without superimposed toxemia, the fetal death rate excluding abortion was 23.3%, and, among those with superimposed toxemia, it was 41%. Essential hypertension is a complicating factor in 25% of all toxemias of pregnancy. Indirect evidence indicates that unrecognizable vascular disease is present in another 25%. Mild hypertension (benign) unassociated with superimposed toxemia offers no additional fetal risk. Mild hypertension associated with superimposed toxemia increases the fetal mortality rate tenfold. Severe hypertension (diastolic blood pressure of 110 or more) with or without superimposition of toxemia results in a high infant mortality rate. When superimposition of toxemia occurs, the fetal mortality is doubled to 41%. Superimposition of toxemia is unrelated to the severity of the hypertension. Spontaneous abortion is not increased in essential hypertension. The more important factor in fetal survival is the time of onset of the superimposed toxemia; 80 to 100% of the fetal loss occurred with the early inception of the superimposed toxemia before the 37th week of pregnancy. The increased frequency of interruption of pregnancy in the past five years has not resulted in any improvement in the fetal survival rate.

Desmoid Tumor of the Popliteal Space Occurring During Pregnancy: Report of a Case with Bioassays. W. B. Ober, J. T. Velardo, R. T. Greene and R. J. Taylor. J. Nat. Cancer Inst. 16:569-578 (Oct.) 1955 [Washington, D. C.].

There is both clinical and experimental evidence that desmoid tumors are in some way related to hormonal activity. They have a tendency to occur in young women during or shortly after gestation. The case presented concerned an 18-year-old woman who was pregnant. In her 17th week of gestation, on Jan. 15, 1954, a mass measuring 3 cm. was observed in the left popliteal space. It had been noted first 6 weeks prior to conception, when it measured 1 to 2 cm. in diameter and was somewhat tender. The mass was fixed to the deeper tissues of the popliteal space, but the overlying skin was freely movable. A clinical diagnosis of Baker's cyst was made, and the patient was instructed to return after delivery for excision. About one month before delivery, the mass had increased two and one-half times in size and was interfering with walking. An incisional biopsy was performed, which revealed that the mass was composed of firm, homogeneous, relatively avascular fibrous tissue. A diagnosis of desmoid tumor was made, and it was decided to defer definitive surgical treatment until after delivery. Twelve days after the woman had given birth to a healthy female infant, an operation was performed. The tumor surrounded the popliteal artery and vein and the peroneal nerve. It was necessary to free the tumor from these structures by sharp dissection. The head of the gastrocnemius muscle, the popliteus, and the head of the semitendinosus had to be excised along with the tumor. At the completion of the operation, the pulses in the extremity were strong and neuromuscular function was unimpaired. The patient was discharged three weeks after operation with considerable improvement in the motion of the knee joint. The tumor weighed 410 gm. and measured 8.5 by 13.5 cm. Saline and ether extracts of the tumor tissue stimulated uterine growth but did not produce cornification of vaginal epithelium in rats. The tumor did not contain assayable estrogenic, progestational, gonadotropic, adrenotropic, or thyrotropic substances. The neutral fraction contained substances that augmented estrogen-induced uterine growth, and the toluene fraction contained substances that augmented estrogen-induced cornification of vaginal epithelium. It is not possible to state with certainty whether the estrogen-augmenting effects observed are characteristic of the tumor or are a property of any tissue removed from a woman 12 days after delivery.

PEDIATRICS

Four Years' Experience with Antibiotic Treatment of Tuberculous Primary Infection in Children in a Preventorium. H. Bour, M. M.-T. Lesueur, Mrs. J. Hébert-Jouas and R. Terdavtian. Semaine hôp. Paris 31:3025-3036 (Oct. 2) 1955 (In French) [Paris, France].

Streptomycin, isoniazid, aminosalicylic acid, and their various combinations were used in the treatment of 409 out of 536 children under 15 years of age with primary tuberculosis of the lymphatic-pulmonary type. All 536 patients were in a special hospital receiving only patients from pediatric or infantile tuberculosis clinics in Paris. The remaining 127 children were given nonspecific therapy and were therefore considered as controls. No significant difference between the two groups was noted. Streptomycin and aminosalicylic acid have no preventive effect on the complications associated with dissemination of bacilli which may appear during treatment. Isoniazid does not seem to have any preventive effect on the local complications of primary infection, but it does appear to stop dissemination. Thus it constitutes the major medicament to be used in the treatment of primary tuberculosis. Streptomycin has special value in the treatment of infants. Aminosalicylic acid is used only in view of theoretical considerations, i. e., because of the danger of bacillary resistance. The only treatment that had any effect on the natural duration of the disease was isoniazid, especially when associated with streptomycin. This association should be used in children less than a year old, after which age isoniazid alone or in combination with aminosalicylic acid is the treatment of choice. The latter treatment has the advantages of being effective in more than half of the cases, being easy to administer and control, and keeping streptomycin in reserve. The therapy must last at least six months. None of the antituberculous agents allow of dispensing with preventorial care with its three essentials: rest, good hygiene, and proper diet.

A Comparison of Intramuscular Benzathine Penicillin and Oral Sulfonamides in the Control of Rheumatic Recurrences. C. M. McCue, C. D. Gibson Jr. and L. C. Lindemann. J. Pediat. **47**:450-460 (Oct.) 1955 [St. Louis].

The influence of monthly intramuscular injections of benzathine penicillin G on rheumatic recurrences in a group of 50 patients selected from the convalescent wards and outpatient department of the Richmond Rheumatic Fever Clinic in the fall of 1952 was compared with the influence of sulfonamides given prophylactically to another group of 50 comparable patients. The same diagnostic criteria were used in both groups and each received the same general care. The average age of the patients in the penicillin group at the start of therapy was 10.2 years, and the mean number of months since the onset of the last rheumatic fever attack was 12. The comparable figures for the sulfonamide group were 11 years and 9 months respectively. Heart disease was present in 78% of the sulfonamide group and in 85% of the benzathine penicillin group, and in a very large percentage of both it was serious in nature. Four patients were eliminated from each group because they failed to follow through. The benzathine penicillin G group received deep intramuscular injections of 1,200,000 units every 28 days. These patients had initial throat cultures and repeat cultures every three months routinely or on suspicion of a respiratory infection. Each patient received an average of 24 injections in a 26-month study period. The sulfonamide group was divided, with 32 on sulfadiazine and 14 on Gantrisin, given according to a previously described schedule with careful observation of leukocytes and urine in the early weeks. Prophylaxis in these children had an average duration of 38.6 months, because in many cases it had been started earlier; in all, however, it was continued through the same period as that of the penicillin group. Throat cultures were also made initially and at three-month intervals, but with less regularity than in the penicillin group, because it was more difficult to get the patients in to the clinic. Not a single recurrence was observed in the penicillin group, although two patients with old failure and enlarged hearts still have smoldering disease. The recurrence rate in the sulfonamide group was 4.3%. One child died of what was apparently an intercurrent infection, and three others had vague aches but no clear-cut recurrences. The value of prophylactic treatment can be seen by comparing these figures with the 61% recurrence rate noted before 1946 in an untreated group in Virginia. The results of this study provide further evidence in favor of the large-scale use of benzathine penicillin G intramuscularly for the prevention of rheumatic recurrences.

On the Prognosis of Childhood Tuberculosis: An 18-Year Follow-Up Report. Nils Levin. Am. Rev. Tuberc. **72**:513-526 (Oct.) 1955 [New York].

This 18-year follow-up report deals with 434 children up to 15 years old first reported on in 1935, in whom roentgenographic examination and culture of gastric washings had frequently been carried out. All had received sanatorium care for suspected or verified active pulmonary tuberculosis. All the children were traced and all but 18 of the survivors have now been reexamined in an investigation made for the purpose of determining the prognosis of various types of tuberculosis in childhood with regard to the age at which the disease develops; the prognostic significance of bacteriological findings in gastric washings at the initial examination; and the causes of death and the duration of survival after diagnosis. Patients followed up have been placed in their original group classifications for the sake of clarity but certain groups have been combined in this report. The 18 survivors who refused reexamination and 8 others, who are either living abroad or were registered as missing, were fairly evenly distributed throughout the various groups, and they have therefore been disregarded. A total of 47 children died; in each case, the pulmonary status at death was satisfactorily determined, and it was found that 34 had died of tuberculous disease. The most interesting findings were those obtained in the group of 254 children in whom the initial investigation showed active tuberculosis of the lungs or hilar lymph nodes. No active tuberculous lesions were revealed by the follow-up roentgenograms in 82% of this group; active disease was present in 5%; and 13% had died of tuberculosis. The mortality rate of the children with primary tuberculosis was 7%, strikingly lower than the 63% of those in whom the disease was postprimary. The mortality in the primary tuberculosis group increased with the age at which the disease was detected; in those with postprimary disease this trend was reversed, except in the children who contracted tuberculosis during puberty. Such children had a death rate of 18% in the primary group and 67% in the postprimary group. The results of bacteriological tests on gastric washings during the acute phase of the disease apparently lacked prognostic significance. Of the patients in whom the initial examination showed primary lesions and gastric washings positive for tubercle bacilli, 88% were without active disease at follow-up and 4% had active lesions, while, of those with negative gastric washings, 92% were without active disease and 4% had active lesions. Five of the 12 patients with active tuberculosis at follow-up were considered fit for work. Analysis of the 34 fatal cases showed that death was due to pulmonary tuberculosis in 26 and to tuberculous meningitis in 8. Most of the deaths from meningitis occurred in early childhood, and none of the children in whom this complication developed survived. It should be noted that these cases originated in the preantimicrobial era; only those patients who still showed active tuberculosis at follow-up had received any antimicrobial drugs.

Tissue Therapy in Seborrhea Sicca and Eczema of Nursling. S. Santyan y Velasco and F. Amore. Clin. pediat. **37**:501-510 (July) 1955 (In Italian) [Bologna, Italy].

Placental extracts used concurrently parenterally and locally to treat nurslings with seborrhea sicca and eczema gave good results, especially in the infants with the first condition. Placental tissue finely dispersed in placental juice ("Histoplac emulsion") or integral placental extract ("Placentex integro") was used for the parenteral route; placental powder incorporated in a 50% oily vitamin medium ("Histoplac cream") was used for the local treatment. The therapy was given to 26 of 52 affected infants, 14 with seborrhea sicca and 12 with eczema. In all but eight the condition had been present and remained unchanged for several weeks or months. The other 26 infants, who served as controls, received no treatment or only local treatment with the standard creams. The Histoplac emulsion was given in doses of 1 cc. every other day for 20 to 30 days and then, in most cases, every three days for 15 to 30 days; the Placentex was given in doses of 1.5 to 2 cc. every three days for 12 to 30 days and then, in most cases, every four days for 15 to 20 days;

and the Histoplac cream was applied to the involved areas once or twice daily. The infants' tolerance for the preparations was good or excellent, with the exception of four in whom a mild infiltration, which disappeared in a few days, was observed at the site of the injection. All the infants were followed for at least three months after discontinuance of the treatment. Recovery was complete and definitive in 10 infants with seborrhea sicca; a frank and lasting improvement was obtained in 2; and some improvement was obtained in 2, but it was followed by relapse and reactivation of the condition. The respective figures for the infants with eczema were four, three, and five. Pruritus, which was a continuous torment for most of the infants, was greatly influenced by the therapy, which also had a favorable effect on their weight. Notable remissions were never observed in the controls. The mechanism of action of placental therapy in these conditions of the nursling is still obscure. The "biogenous stimulators" (biostimulins) of Filatov do not as yet have a chemical identity, although recently some authors, among them Filatov himself, have compared these factors to the nucleic acids. It is definite that the therapy did not exert its action in these infants by means of endocrine substances of the gonadotropin and estrogen type contained in the placenta, because these were removed in the preparation of the extracts that were used by the authors. Studies are in progress to investigate this mode of action.

Gastric Digestion of Homogenized Milk in Infants. A. Adam and E. Czech. Monatsschr. Kinderh. **103:**361-365 (Aug.) 1955 (In German) [Berlin, Germany].

Although it is generally accepted that homogenized milk is more easily digested than ordinary cow's milk, the value of this milk in the feeding of infants is still being disputed. The authors decided to ascertain whether the quantity of gastric juice that is produced after feeding with homogenized milk differs from that produced after feeding of ordinary cow's milk. Their investigations were made on 18 infants, ranging in age from six weeks to eight months. Comparative tests were made with homogenized and nonhomogenized milk. By means of the sugar curve of the stomach, it was ascertained that in 15 of the 18 infants less gastric juice was required for the digestion of homogenized than for the digestion of nonhomogenized milk. In three of the infants the gastric sugar curves were atypical due to secretory anomalies of the stomach. On the basis of their observations, the authors conclude that homogenized milk deserves wider use in the feeding of infants.

OTOLARYNGOLOGY

Hydrocortisone-Antibiotic Therapy in Upper Respiratory Infections. A. H. Persky. A. M. A. Arch. Otolaryng. **62:**354-356 (Oct.) 1955 [Chicago].

The observations reported here were made over an eight-month period on 109 patients. The study was undertaken to determine what value a topically applied hydrocortisone-antibiotic combination might have in treating a wide variety of upper respiratory infections. The medicament, which was dispensed by drops and by means of a plastic spray bottle, had the following formula: hydrocortisone alcohol, 0.02%; hydroxyamphetamine hydrobromide, 0.5%; phenylephrine hydrochloride, 0.125%; Gramicidin, 0.005%; neomycin sulfate, 0.1%; and polymyxin B sulfate, 0.2 unit per milliliter. Patients were instructed to instill 3 squeezes of the spray bottle or one dropperful of the solution into each nostril every three hours; each method delivers 0.2 cc. of the medicament to each nostril. The efficacy of this treatment was determined objectively by clinical observation of the nasal membrane, and, subjectively, by interviews with the patients. Eighty-five of the patients had upper respiratory infections; of the remaining 24 with uninfected inflammation, 3 had hay fever, 7 had chronic hyperplastic ethmoiditis, 12 had allergic vasomotor rhinitis, and 2 had chronic nasopharyngitis. The objective results were considered excellent in 21, good in 70, fair in 10, and poor in 8 patients. The subjective results were excellent in one, good in 81, fair in 18, and poor in 9 patients. Most patients tolerated the medication well. It not only relieves the nasal congestion for five or six hours but also decreases bacterial activity and ameliorates nasal inflammation.

Antibiotic Specificity in Ear, Nose, and Throat Infections. L. J. Goldstein and S. Daly. A. M. A. Arch. Otolaryng. **62:**384-389 (Oct.) 1955 [Chicago].

During nine years after World War II, approximately 45,000 veterans were treated at the Ear, Nose, and Throat Clinic of the New York Regional Office of the Veterans Administration. Most of the chronic infections proved to be resistant to the sulfonamides and to penicillin. It became imperative to study the bacterial flora to find what antibiotic to use in each patient. These studies revealed that hemolytic Staphylococcus aureus, Proteus vulgaris, and Pseudomonas aeruginosa were the most common pathogens in chronic suppurative disease of the ears and sinuses. Individual culture and sensitivity tests were absolutely necessary for the proper treatment of the chronic infections. The authors strongly urge the combined use of two antibiotics, because, by attacking the enzyme systems of the bacteria in different ways, the development of resistant strains is prevented. They gained the impression, however, that both P. vulgaris and P. aeruginosa, in the strains obtained from fresh purulent exudate, are becoming more resistant to all available antibiotics.

Rhinopharyngeal Fibroma. E. Christiansen. Ugesk. læger **117:** 1153-1156 (Sept. 1) 1955 (In Danish) [Copenhagen, Denmark].

In the four cases of rhinopharyngeal fibroma described, in males aged 19 to 59, there were nasal stenosis, purulent secretion from the nose, and intermittent hemorrhage. Macroscopically the tumor is grayish red (depending on the vascularization), hard, fibrous, with smooth surface. There is no evidence of malignant degeneration. Histologically the tumor is an angiofibroma, partly with, and partly without muscular tissue in the wall. The vessels can become so numerous as to suggest cavernous tissue. In cases with doubtful diagnosis, biopsy must be done. The patients were treated with extirpation orally. There were no complications, and the operation has given satisfactory results. The danger is from hemorrhage.

THERAPEUTICS

Experiences with Metacortandracin (Meticorten) in Severe Bronchial Asthma. J. M. Sheldon, J. A. McLean and K. P. Mathews. J. Michigan M. Soc. **54:**1081-1083 and 1093 (Sept.) 1955 [St. Paul, Minn.].

The authors present experiences and observations on a group of 51 patients with severe asthma who had responded poorly to other accepted methods of therapy. Metabolic studies are detailed on the 15 patients who had been observed for the longest period of time. The group is rather unusual, in that 11 were aspirin-sensitive and 23 had infectious (intrinsic bacterial) asthma. In the remaining 17 patients, the asthma was of a mixed type or due to extrinsic protein sensitivity. Thirty-six of the patients had previously received cortisone, hydrocortisone, or corticotropin, and 11 of this group had taken a daily dose of 75 to 200 mg. of cortisone continuously for a period of from three months to three and one-half years before the medication was changed to Meticorten, which is also known as prednisone. About one-third of the patients were hospitalized for from 8 to 21 days, while the others were observed as outpatients. During hospitalization, the blood pressure, weight, eosinophil counts, and vital capacity determinations were recorded daily; 24 hour urinary 17-ketosteroid determinations were made before and at varying intervals after the administration of Meticorten; a routine urinalysis was made each week, and the chest was examined each day. Upon discharge these studies were repeated at weekly intervals. A similar investigation was carried out in all cases managed as outpatients. The initial dosage of Meticorten consisted of divided doses of 25 mg. daily in 46 and 35 mg. in 5 patients. When maximum improvement with complete asthmatic control occurred, the Meticorten dosage was gradually reduced by 5 mg. per day. The drug proved to be very effective for the temporary, symptomatic relief of bronchial asthma. In all but one of the 51 patients, satisfactory clinical control was obtained. However, as with other steroids, relapse usually occurred when the drug was withdrawn. Hence, it is not a substitute for the specific etiological management of the asthmatic patient. However, in a number of instances this drug proved to be more satisfactory than other steroids or adrenocorticotropic hormone. Three patients have been free from the recurrence of asthma for from 60 to 86 days. Undesirable side-effects appear to be less frequent than with other hormones, and dietary restriction was not necessary. The period of observation is far too short and the number of patients observed is too small to permit final conclusions, particularly in regard to possible side-effects from prolonged treatment.

Nine-Alpha-Fluorohydrocortisone. L. de Gennes and G. Deltour. Presse méd. **63**:1214-1215 (Sept. 17) 1955 (In French) [Paris, France].

The history of 9-α-fluorohydrocortisone (Compound FF) is reviewed. The authors made a few preliminary trials of the drug as replacement therapy in patients with adrenal cortical hypofunction (Addison's disease). The results were encouraging for clinical application of this agent in the future. At the moment, however, Compound FF does not seem to be susceptible to use as the only substitutive agent in this disease, because it causes severe sodium and water retention and massive potassium excretion. Even in small doses 9-α-fluorohydrocortisone is capable of producing edema or grave accidents of hypokalemia. Its advantages are strong glucocorticoid and mineralocorticoid action, effectiveness by the oral route, and prolonged effect. The drug produces no ill-effects when applied externally and is therefore useful in the treatment of inflammatory dermatoses.

Clinical Contribution to the Use of Hydrocortisone by the Oral Route. E. Cecchi and F. Ferraris. Policlinico (sez. prat.) **62**:1132-1137 (Aug. 22) 1955 (In Italian) [Rome, Italy].

Alcohol-free hydrocortisone was given orally to 35 patients with rheumatoid arthritis in average daily doses of 80 mg. for two weeks and 30 mg. thereafter for almost four months. All of the patients showed clinical and roentgenographic signs of active disease and joint involvement. The disease was in the second stage in 24 patients and in the third stage in the others. A complete remission was obtained in the two patients in whom the disease was rather mild. In the others, the condition of the joints was benefited and the functional capacity was increased. The erythrocyte sedimentation rate dropped, as did leukocytosis, when present; hyperglobulinemia became less marked; and the albumin-globulin ratio tended to become normal. Despite the clinical improvement, the roentgenographic findings remained unchanged. Oral administration of the preparation in daily doses of 140 mg. for two weeks and then 60 mg. daily controlled the severe symptoms that were present in one patient with lupus erythematosus disseminatus. Three months after the therapy was started, the patient's general condition was satisfactory. Four patients with bronchial asthma were given 200 mg. of hydrocortisone orally on the first day and progressively decreasing doses of it thereafter until a daily maintenance dose of 10 or 20 mg. was reached. The effect was brilliant in all with disappearance of the dyspnea and of the pulmonary findings; one month after discontinuance of the therapy, the improvement was still present. Oral hydrocortisone therapy had good effects also in two patients with nephrosis and one with ulcerative colitis. It improved the general condition of, and controlled the hemorrhages in, two patients with thrombopenic purpura, but it did not bring about an increase in the number of platelets. The therapy had no effect in two patients with subacute myeloid leukemia and in one with aplastic anemia secondary to Hodgkin's disease that had been treated with mustard gas. The side-effects of the therapy were few, not too severe, and were easily controlled by reducing the dose of hydrocortisone.

Antibiotic-Resistant Staphylococcal Infection: A Study of Antibiotic Sensitivity in Relation to Bacteriophage Types. M. Barber and J. Burston. Lancet 2:578-582 (Sept. 17) 1955 [London, England].

When penicillin-resistant infection first became a problem, reports emphasized that most cases were the result of cross infection and that the only way to stem the tide was to increase the aseptic control, but what is regarded as good aseptic control has failed. The studies described were undertaken to ascertain the reasons for this failure. Of 62 babies born in a maternity unit, 55 left the hospital carrying penicillin-resistant strains of Micrococcus (Staphylococcus) pyogenes var. aureus in the anterior nares. A study of antibiotic sensitivity patterns and bacteriophage types suggested that in most cases the babies had acquired these organisms from the nurses rather than from their mothers. There were no serious cases of sepsis. Strains of M. aureus were isolated also from 100 infective processes in other departments; 59 of these were resistant to penicillin, 30 to streptomycin, 26 to oxytetracycline, and 3 to chloramphenicol. Strains sensitive to antibiotics were isolated mostly from outpatients and from patients admitted with closed abscesses, whereas a large number of antibiotic-resistant infections appeared to have resulted from hospital cross infection. In the present investigation, 53 strains of M. aureus were found to be resistant to one or more of three antibiotics and all were of phage group 3. Strains of phage group 3 appear to yield antibiotic-resistant variants more readily than do other strains of M. aureus. Of 26 infections occurring after operations in the general surgical wards, none was due to an antibiotic-sensitive strain, and 17 were due to strains resistant to penicillin, streptomycin, and the tetracyclines. Two ways are suggested in which the problem can be attacked. The first is to keep clean surgical cases separate as far as possible; they should not be in the same ward with patients who have extensive superficial micrococcic (staphylococcic) lesions, which cannot be covered and must therefore infect the environment. The second is the intelligent local use of antibiotics. Local treatment with antibiotics for long periods is one of the best ways of rendering an organism resistant and should therefore be avoided. An exception to this rule is neomycin, and this antibiotic, or the synthetic compound 1:6-di-4'-chlorophenyl-diguanidohexean ("Hibitane"), is probably the most suitable agent for the local treatment of micrococcic lesions. More important than this, however, is to keep at least one antibiotic in reserve.

Two New Synthetic Steroids: Prednisone and Prednisolone. M. Pestel. Presse méd. **63**:1179 (Sept. 10) 1955 (In French) [Paris, France].

Two compounds have been recently synthesized that seem to have the same anti-inflammatory and antirheumatic properties as cortisone and hydrocortisone but do not cause water and salt retention in the usual doses. They are prednisone (Δ_1 dehydrocortisone), or metacortandracin, and prednisolone (Δ_1 dehydrohydrocortisone), or metacortandralone. They have a greater anti-inflammatory and a greater glucocorticoid activity than the older drugs; in fact, they have been shown to be three or four times more potent than cortisone and hydrocortisone. At the same time, the new drugs have less effect on the lymphatic system and cause less disturbance of water and electrolyte metabolism. As to toxic effects, the drugs are well tolerated but cause suppression of the circulating lymphocytes and increase in the polynuclears; prednisolone is considerably the more powerful in this regard. The effect is reversible on cessation of treatment. Prednisone is also the more powerful in suppressing normal growth of the spleen and causing thymic involution; this effect also is transitory. One advantage of therapy with the new steroids is greater dietary freedom for the patient. The drugs augment protein catabolism and cause a decrease of potassium. It is advisable to administer anabolic steroids in association with them, especially when massive doses are being used. Estrogens or testosterone can prevent depletions of calcium or phosphorus. Patients given the drugs must, as always, be carefully watched, and there are various contraindications, of which tuberculosis is the strictest. Doses must be individually adjusted. In general, in a patient with acute articular rheumatism, 20 or 30 mg. a day is a good starting dose, followed by 2.5 to 5 mg. a day after the first therapeutic effects have been noted.

RADIOLOGY

Treatment of Multiple Myeloma with Radioactive Iodine and Radioactive Iodinated Serum Albumin. J. P. Kriss, H. R. Bierman, S. F. Thomas and R. R. Newell. Radiology **65**:241-249 (Aug.) 1955 [Syracuse, N. Y.].

Of 17 patients between the ages of 40 and 70 years with multiple myeloma, 9 were given systemic treatment with radioactive iodine (I^{131}) and 7 with radioactive iodinated serum albumin (RISA). Each of the patients treated with I^{131} was given about 150 mc. of the isotope orally after preliminary stable iodide treatment. Three of the nine patients received a single dose, while the other six were given a series of treatments up to a total dose of 510 mc. Radioactive iodinated serum albumin was given intravenously in doses of 10 to 20 mc. Four of the seven patients received a single dose, and three were given a series of treatments up to a total dose of 42 mc. Of the nine patients treated with I^{131}, four gained strength and were relieved of pain; the same results were obtained in three of the seven patients treated with RISA. Relapse in three to four months was the rule. If relapse occurred, retreatment was usually effective. In two patients, the rapidly progressing disease was apparently arrested for 15 months with I^{131} and for 9 months with RISA respectively. Anemia was not improved; there were no lasting changes in serum protein pattern; and marked recalcification of bony lesions did not occur. In view of the paucity of the objective evidence of improvement, it is prudent to regard the effects of I^{131} as palliative only. Mild radiation sickness occurred in about one-third of all patients. Consideration may be given to treatment with I^{131} or RISA when whole body irradiation is desired, if the patient is not ambulatory or cannot be easily moved for x-ray therapy, if local x-ray treatment is inadvisable because painful areas are too numerous, and if skin tolerance to roentgen rays has been exhausted. RISA must be given by vein, but it is more economical of the isotope, and its dose is below the level for which the Atomic Energy Commission requires hospitalization. Radioactive iodine, as iodide, can be given by mouth; it is preferable to RISA if it shows selective localization in the lesions. Either of the two radioactive agents will destroy the thyroid if its uptake is not blocked.

Roentgenologic Aspects of Chordoma. J. R. Utne and D. G. Pugh. Am. J. Roentgenol. **74**:593-608 (Oct.) 1955 [Springfield, Ill.].

Chordoma is one of the few neoplasms that originate from and retain the histological structure of primitive embryonic tissue. It originates from remnants of the notochord, grows slowly, is locally invasive, but tends to recur after surgical removal. Because of its insidious growth, it may be present for long periods before treatment is sought. This report is based on the records of 72 patients with histologically proved sarcoma, which were found in the files of the Mayo Clinic from 1910 to 1953. Original roentgenograms made prior to treatment were examined in 41 cases. Thirteen of the patients are reported for the first time. Since more than 500 cases have been reported in the literature, chordoma is not so rare as is commonly assumed. The high incidence of previous injury, the distribution of the lesions, and the preponderance in the male sex suggest that trauma may be a predisposing factor. Gross examination of the tumor reveals a round, irregular, encapsulated mass composed of gelatinous or mucoid tissue, the lobules of which are separated by fibrous septa. The microscopic picture shows the large physaliphorous cells with the typical arrangement in cords or strands lying in a sea of mucus. The similarity of the clinical and roentgenographic manifestations of cranial chordomas to other intracranial neoplasms precludes a correct preoperative diagnosis in most cases, but a chordoma should be considered in the differential diagnosis of all midline tumors at the base of the brain. The presenting complaints and roentgenologic findings of vertebral chordomas reveal no distinguishing characteristics to differentiate them from other tumors of the spinal column. In sacrococcygeal chordoma, however, the correct preoperative diagnosis is possible in nearly half of the cases, chiefly because of the prolonged clinical course and rather typical roentgenologic manifestations. Roentgenographic evidence of bone involvement or of a soft tissue mass is found in more than 90% of patients with chordoma.

PHYSIOLOGY

The Houssay Phenomenon in Man. J. C. Harvey and J. de Klerk. Am. J. Med. **19**:327-336 (Sept.) 1955 [New York].

The Houssay phenomenon, or hypoglycemia and a marked increase in sensitivity to insulin, rarely occurs in man; when it does, it is usually caused by infarction of the anterior lobe of the pituitary gland. One of the first effects of the anterior pituitary insufficiency is hypoglycemia, which follows within 24 hours after the infarction and is manifested by bizarre and rapidly changing neurological signs associated with loss of consciousness. The patients, who have usually had diabetes mellitus for a considerable time, exhibit extreme sensitivity to administered insulin. Those who have survived the acute phase of the illness have begun within a month or two to exhibit the clinical manifestations of thyroid, adrenal, and gonadal hormone deficiency. Diabetes in these patients is ameliorated, but by no means cured. The symptoms of diabetes disappear, glycosuria decreases, and the sugar in the blood approaches the normal level, but the diabetic tendency remains and the response to the stress of intravenously administered glucose is still diabetic in type. Continued administration of insulin is sometimes necessary, but the "Houssay man" is quite as sensitive to insulin as the "Houssay dog," and hypoglycemia is always a threat to life. The excellent results that can now be obtained in patients with panhypopituitarism by judicious hormone replacement therapy make the early recognition of pituitary insufficiency a matter of vital importance. It should be immediately suspected in patients with diabetes if their insulin requirements decrease rapidly or if insulin shock occurs with great frequency and hypoglycemia is prolonged and relatively resistant to the intravenous administration of glucose. Three such patients have been seen at the Johns Hopkins Hospital: one was a 22-year-old white woman in the ninth month of her first pregnancy; another was a 68-year-old white man with benign prostatic hypertrophy, who had been found to have diabetes at the age of 58; and the third was a 40-year-old Negro, admitted in 1949 to another hospital in severe diabetic acidosis. The complaint common to these patients and several of those previously reported on in the literature was severe headache, recognized in retrospect as having been felt at the time the pituitary infarction must have occurred. The first two patients died, but the third is still alive. He has refused replacement hormone therapy, although he has clearcut signs of thyroid, adrenal, and gonadal hormone deficiencies. His diabetes is improved, apparently as a result of pituitary insufficiency caused by generalized sarcoidosis involving the pituitary gland.

Relationship of Sodium Retention and Venous Pressures to Edema Formation. R. Goldman and S. H. Bassett. Circulation **12**:630-634 (Oct.) 1955 [New York].

Two patients with congestive cardiac failure were placed on a metabolic balance regimen, and supplemental sodium chloride was administered. The retention of water induced by the sodium supplementation amounted to over 3 kg. and presented as clinical edema. In neither of these two patients was the edema preceded by an increase in the brachial venous pressure. This observation supports the concept that retention of fluid in heart failure does not depend upon an initial elevation in venous pressure.

BOOK REVIEWS

1/2

Roentgen Interpretation. By George W. Holmes, M.D., Radiologist to Waldo County Hospital, Belfast, Maine, and Laurence L. Robbins, M.D., Radiologist-in-Chief to Massachusetts General Hospital, Boston. Eighth edition. Cloth. $10. Pp. 525, with 371 illustrations. Lea & Febiger, 600 Washington Sq., Philadelphia 6, 1955.

This new, enlarged, and more detailed edition of one of the oldest and most honored textbooks in roentgen diagnosis is most welcome. While some of the reproductions of roentgenograms of the chest do not depict the processes described, the illustrations as a whole are greatly improved and are shown as negatives. The text is unusually complete for a book of this size and suggests that the authors were attempting to produce a textbook for students, a guide for general physicians, and a handbook for radiologists. The limitation in the number of illustrations always presents a problem of selection. The authors have attempted a compromise between illustrating unusual or rare conditions and concentrating on common situations. While such efforts at reaching a variety of readers often prove unsatisfactory, in this volume some success has been achieved. It is unfortunate that more attention was not given to radiographic technique or the basic principles of roentgen diagnosis, information much needed by the student and general physician. Insufficient attention is given to the dangers involved in roentgen diagnosis and to methods of protecting the patient. This material is covered in the good chapter on fluoroscopy but only incidentally; the false impression may be gained that there is no danger in radiography. There are a number of errors of minor significance. It is surprising to find the statement that foreign bodies in the bronchi occasionally produce emphysema when this is the common early change. Also the reference to "ball-valve" obstruction of the bronchi as if it were synonymous with "check-valve" is erroneous. Of its many good features, an excellent table summarizing the usual findings in bone tumors and a good elucidation of many pulmonary conditions are notable. On the other hand, considering the present interest in carcinoma of the lung, it is surprising that more space was not devoted to this subject. On the whole, this is a complete, concise, well-written, and well-illustrated textbook covering fluoroscopy and the interpretation of roentgenograms in an adequate fashion.

Keratoplasty. By R. Townley Paton, M.D., F.A.C.S., Surgeon Director, Manhattan Eye, Ear and Throat Hospital, New York. Cloth. $28.50. Pp. 280, with 87 illustrations. Blakiston Division, McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 36; 95 Farringdon St., London, E.C.4, England, 1955.

In this book the chapter on the history of corneal transplantation makes the reader aware of the fact that the more modern views on this subject are merely refinements and new adaptations of old and basic concepts; it also points up the drama of the emotions of the early pioneers in the field. The author reviews in minute detail the physiology of the cornea, but the complex problem of transparency remains unsolved. Under case selection, with the increasing number of reports on keratoplasty, clinical criteria for the selection of favorable and unfavorable cases are further amended, refined, and altered. As a supplement to his own views, techniques, and experiences, Dr. Paton carefully and critically reviews the techniques of some of the ophthalmic surgeons prominently associated with corneal transplantation. The book is superbly illustrated with color plates and black and white photographs and drawings that demonstrate preoperative and postoperative results, successes and failures. The history, role, purposes, and goals of the Eye-Bank for Sight Restoration, Inc., and the newer procedures legalized throughout the world for securing cadaver corneas are thoroughly discussed. Dr. Paton classifies those patients who require lamellar, penetrating, or tectonic grafting and guides the reader in the selection and preparation of patients, grafting techniques, postoperative and adjuvant treatments, and the treatment of early and late complications. Corneal healing after transplantation is discussed, including the various theories as to the fate of the graft, the regeneration of corneal nerves, corneal vascularization, and the *maladie du greffon*, or illness of the graft, which is still very perplexing and discouraging. The statistical table of results of corneal grafting in all types of corneal clouding, due to congenital dystrophies, disease, deformities, and/or traumatic injuries, enables the reader to determine that the diverse percentages of clear grafts in the different categories are directly proportionate to the varying degrees of corneal opacity and vascularization. With this information, the surgeon can predict fairly accurately the chance for a successful graft in most cases. The book contains particularly useful reference material for the ophthalmic surgeon performing corneal grafting, or for the ophthalmologist consulted for advice and the possible outcome of such grafting. Hospitals contemplating the establishment of eye and tissue banks should find it of value.

Fractures and Joint Injuries. Volume II. By Sir Reginald Watson-Jones, F.R.C.S., F.R.A.C.S., M.Ch.Orth., Extra-Orthopædic Surgeon to Her Majesty the Queen, London. Fourth edition. Cloth. $22 (2 volumes). Pp. 445-1073, with 904 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1955.

More than two years have elapsed since the first volume of the fourth edition of this opus was published. It is clear that this eagerly awaited volume has been extensively revised. Many new illustrations have been added, redundant and out-of-date material has been deleted, and new methods of treatment that have assumed a greater importance in the management of certain fractures have been emphasized. For example, the section on acute and recurrent dislocation of the shoulder joint has been entirely rewritten and the need for immobilization of the initial injury has been properly emphasized. In the same way, it is now recognized that fractures of the neck of the femur, formerly classified as abduction and adduction fractures, are due to external rotatory strains and the roentgenographic appearances are merely due to the different degrees of rotation and displacement that arise from varying degrees of lateral rotation. Treatment of fractures of the neck of the femur is wisely dealt with, and the place of the femoral head prosthesis receives proper emphasis. The use of intramedullary nailing in the treatment of certain fractures of the femur, humerus, and other bones is given its proper place. The section on maxillofacial injuries has been extended and brought up-to-date. Fracture of the spine with paraplegia is wisely discussed, and the advantages of early internal fixation of the spine, in the presence of paraplegia, is emphasized. Throughout this volume one senses the author's interest and concern with rehabilitation and the return of the injured patient to work. This monograph is at once the most complete, the most balanced, and the best-written textbook of its kind in the English language.

Anesthesia in Ophthalmology. By Walter S. Atkinson, M.D., Associate Clinical Professor of Ophthalmology, New York University Post-Graduate Medical School, New York. Publication number 251, American Lecture Series, monograph in American Lectures in Ophthalmology. Edited by Donald J. Lyle, M.D., F.A.C.S., Professor of Ophthalmology, College of Medicine, University of Cincinnati, Cincinnati. Cloth. $3.25. Pp. 101, with 44 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1955.

The author has prepared this brief monograph almost exclusively for the surgeon and devotes most of the pages to a discussion of local anesthesia. The required techniques are simple and are adequately discussed. Most of the illustrations are well done. The author uses procaine, tetracaine, or lidocaine and ordinary standard equipment, syringes, and needles. The discussion of preanesthetic preparation is straightforward and conservative; however, the doses of barbiturates, chloral hydrate, and meperidine suggested in this monograph would be considered by many as generous, although the author previously

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

warns against using too large a dose. The pages devoted to the psychological preparation of the patient are timely and well chosen. The complications from drugs are stressed with some humorous illustrations. General anesthesia is mentioned with little more than the statement that it is indicated for children, for extensive ocular operations, and for those objecting to local anesthesia. The author is willing to leave its choice and administration to an anesthesiologist if one is available. The monograph should be useful and of interest to those practicing, preparing to practice, or teaching ophthalmology.

Textbook of Endocrinology. Edited by Robert H. Williams, M.D., Executive Officer and Professor of Medicine, University of Washington Medical School, Seattle. Contributors: William H. Daughaday and others. Second edition. Cloth. $13. Pp. 776, with 173 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, England, 1955.

This second edition of a textbook that first appeared in 1950 has been prepared by the same group of 10 collaborators with the exception of Dr. L. H. Newburgh, who has been replaced by Dr. Daughaday, and the late Dr. E. J. Kepler, whose contribution has been revised by other contributors. The subject matter has been brought up-to-date without materially changing or enlarging the book. The book in general follows the usual approach to the subject, with the individual chapters differing in the relative attention given to the basic theoretical and practical clinical aspects of the subject. For example, the chapter entitled Diseases of the Parathyroid Glands occupies 98 of the 743 pages of the book. The thymus and pineal, although admittedly of little importance, receive no notice. This defect, inherent in any textbook of multiple authorship, must render such books uneven and less well correlated than those of a single author. In general, however, the present volume is sound and the treatment of some aspects of endocrinology excellent. The format and type are excellent and the illustrations well chosen, although some of the radiographs are too poorly reproduced to be of value. The book can be recommended to the practicing physician.

Advances in Cancer Research. Volume III. Edited by Jesse P. Greenstein and Alexander Haddow. Cloth. $8.50. Pp. 369, with illustrations. Academic Press, Inc., 125 E. 23rd St., New York 10, 1955.

This book summarizes the progress made in certain phases of cancer research. Its reviews appear to be thoughtfully organized and include such subjects as the etiology of lung cancer, the experimental development and metabolism of thyroid tumors, new developments in the electronic structure and carcinogenic activity of aromatic molecules, carcinogenesis, pulmonary tumors in experimental animals, and the oxidative metabolism of neoplastic tissues. Each review is well documented by an extensive bibliography. Except for the review by Doll, the material is probably too didactic and theoretical for the clinician or practitioner; however, it should be of interest to research workers in the field of experimental cancer and should find its way into the libraries of institutions where basic cancer research is in progress.

Diagnosis of Congenital Heart Disease: A Clinical and Technical Study by the Cardiologic Team of the Pediatric Clinic, Karolinska Sjukhuset, Stockholm. By Sven R. Kjellberg, Edgar Mannheimer, Ulf Rudhe and Bengt Jonsson. Cloth. $22. Pp. 649, with 581 illustrations. Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11, 1955.

Although this book is based on clinical and roentgenographic studies of 396 patients with congenital heart disease, the authors have reviewed the literature for each abnormality. The result is an up-to-date presentation of what is known about each congenital cardiac lesion in respect particularly to its clinical recognition. The illustrations, which are numerous, are of excellent quality, particularly the angiocardiograms. Studies, where possible, in each case included cardiac catheterization, angiocardiograms, electrocardiograms, heart sound records, and electrokymography. The first chapter is devoted to embryology with particular attention to mechanisms by which maldevelopment can produce congenital cardiac lesions. This is followed by a section describing the techniques used in examination. The various congenital lesions discussed in the succeeding chapters include pulmonic stenosis, tetralogy of Fallot, persistent truncus arteriosus, ventricular and atrial septal defects, anomalous drainage of pulmonary veins, patent ductus arteriosus, coarctation of the aorta, subaortic stenosis, and other rarer anomalies. The authors have done a fine job in this careful clinical study of a large series of congenital cardiac lesions. Their work should help materially to establish sound criteria for the clinical diagnosis of a number of congenital lesions heretofore difficult to diagnose during life. This is one of the really good recent books on congenital heart disease. It is a good reference book for the pediatrician and the internist interested in cardiology.

Clinical Orthopaedics. Number Five. Anthony F. DePalma, editor-in-chief. With assistance of associate editors and board of advisory editors. Cloth. $5. Pp. 242, with illustrations. J. B. Lippincott Company, 227-231 S. Sixth St., Philadelphia 5; 2083 Guy St., Montreal, Canada; Pitman Medical Publishing Company, Ltd., 39 Parker St., Kingsway, London, W.C.2, England, 1955.

This volume is in the general format of the previous volumes in this series. It is advantageous to have a single subject carried as a major theme of each volume, and this one contains several good articles on backache. Some of the articles have been previously published, so that little of the material is entirely new. It is, however, a good grouping of papers on this subject. A summary is presented at the end of each article. The latter part of this book might have been more carefully edited as to subject matter and the conclusions drawn therefrom, many of which are controversial. The book is well documented, is of convenient size, and is easily read. It is hoped that the authors will continue with this type of presentation.

Poet and Psychiatrist, Merrill Moore, M.D.: A Critical Portrait with an Appraisal of Two Hundred of His Poems. By Henry W. Wells. Cloth. $5. Pp. 325. Twayne Publishers, 31 Union Sq. West, New York 3, 1955.

A sonnet, ere the days of Merrill Moore,
Was looked upon as an accomplishment—
To quarry blocks of words from mother lodes,
Haul them away from where they were before,
Hammer and chisel them till they were bent
Into new combinations, different modes,
Then rearrange and polish, make them shine,
Garnishing fresh ideas in fresher style.
So hours and days, and sometimes weeks and years,
Were spent to make one sonnet superfine.
Great poets made a few in a long while—
A task so difficult it caused them tears.
This has been rectified by Merrill Moore,
His day is wasted that yields not a score.

How is it that this buccaneer of sonnets
Continues almost profligate of rhyme
Since he has other full-time occupations,
As helping those confused with bees in bonnets
(And psychiatric treatment feeds on time)
By balancing depressions with elations.
For recreation, when not writing verse,
He photographs the world from every angle,
In number matching sonnets with his snapshots.
Great volume does not make their goodness worse.
Conchology and finding shells that spangle,
A hobby that prevents reposeful nap plots.
He is a husband, father, soldier, teacher,
Physician, poet, everything but preacher.

Whence comes this energetic cavalier
Who can combine a dozen occupations
And bring to each accomplishment its grace?
The answer to his multiple career,
Achievements in a hundred combinations,
Is told by Henry Wells. He says the place
To find the cause of his fecundity
And his exuberance is in his verse.
Autobiography most clearly tells.
The South gave family, warmth, and human pity,
New England sharpened without making terse.
Their intertwining is described by Wells,
So in the end we learn just how from Merrill—he
Writes wisely and enormously and merrily.

QUERIES AND MINOR NOTES

DIFFERENCES IN SEDIMENTATION RATE VALUES

To the Editor:—*The number of methods published for determining the sedimentation rate has created a problem in that different authors list different normals for the same method. For example, Stewart and Dunlop's "Clinical Chemistry in Practical Medicine" (ed. 4, Baltimore, Williams & Wilkins Company, 1954), gives Westergren normal 2 to 5 mm. per hour, with readings above 12 mm. per hour as definitely abnormal, whereas in Kolmer's "Clinical Diagnosis by Laboratory Examinations" (New York, Appleton-Century-Crofts, Inc., 1943) the normal is given as up to 15 mm. per hour for men and up to 20 mm. per hour for women. In "An Index of Differential Diagnosis of Main Symptoms" (ed. 8, Baltimore, Williams & Wilkins Company, 1954), Westergren method is quoted, with the following statement made regarding correction for anemic blood, "A slightly raised sedimentation rate, say 10 to 20 mm. in the first hour, should not be regarded as significant until the patient has shown to have no anemia, for a reduction of the red cells to about 4 million would be sufficient to account for such an increase." Stewart and Dunlop, however, state that in their opinion only when a large bore tube is used must a correction for anemia be made. They believe that the red blood cell count may be ignored when the small bore Westergren tube is used. I have read that Cutler denies the necessity for using a blood correction when his method is used. Please discuss this problem.*

M.D., Michigan.

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—No wonder there is confusion concerning normal values and the proper method for determining the erythrocyte-sedimentation rate. Dozens of methods have been described, various times for reading (from a few minutes to 24 hours) have been advocated, and various correction factors have been proposed. Some recommend reports based on curves, while others have been satisfied with a single reading. The test, although useful, must be looked on as nondiagnostic of any particular disease and of prognostic value only under limited conditions. Westergren (1921) stated that the blood was to be diluted 1:4 with 3.8% sodium citrate dissolved in water. The test was to be set up in a tube 30 cm. long with an inside diameter of 2.5 mm. and a scale of 200 mm. equivalent to 1 ml. of blood. His normal values were given in a footnote that stated that, on study of 12 men who said they were healthy, 10 had a 2 mm. fall in one hour and 2 had a 5 mm. fall. He cautioned against dogmatic interpretation of normal values and ventured the opinion that a higher value than 3 mm. in one hour seldom occurred and that 10 mm. was rare in healthy persons. He did not establish separate values for men and women but quoted Fåhraeus as reporting that in men the sedimentation rate was 2 mm. in one hour and in women 5 mm. Since then, values for the Westergren method in normal persons have been greatly extended. For example, Sunderman and Boener list for men, 1 to 3 mm., and for women, 4 to 7 mm. Todd and Sanford, and Wells, list normals for men for one hour as 0 to 15 mm., for women as 0 to 20 mm. Similar statements could be made concerning almost every other method. Cutler advocates the use of a curve for determining the sedimentation rate and states that for all practical purposes a maximal settling in five minutes of 1 mm. or less is normal; everything else is abnormal and therefore pathological. However, Wells has given normal one hour rates for the Cutler method as 2 to 8 mm. for males and 2 to 10 mm. for females. Similar values are given by Sunderman and Boener.

The Wintrobe and Landsberg method, which has enjoyed widespread use, makes use of solid anticoagulants instead of liquid ones and utilizes a tube 110 mm. long and of 3 mm. bore. Readings are made at the end of one hour. Wintrobe and Landsberg are the chief exponents of correcting the sedimentation rate in relation to the cell volume. They found that when such corrections were applied the sedimentation rate in 72% of men and women ranged from 0 to 6 mm. and in an additional 16% from 7 to 10 mm. The questioner is correct in stating that Cutler denied the necessity for using a correction for the number of erythrocytes when his method is used. Westergren certainly did not use such a method of correcting for the erythrocyte count or cell volume, and others, while calling attention to the possible advantage, do not make use of such corrections.

A large number of factors affect the sedimentation rate. Some of these are the fibrinogen and protein content of the plasma; the size, volume, and shape of the cells; the degree of rouleau formation; the temperature of the room in which the test is conducted; and to some minor extent the type of anticoagulant used. From these and other considerations it is obvious that normal values are subject to variation and no such values should be considered as hard and fast. Correcting for the cell volume will only complicate the test. As a rule of thumb, one should not consider values in the Westergren method of less than 15 mm. for men and 20 mm. for women as being necessarily pathological or significant (blood dilution 1:10). For the Cutler method, if the hour reading is to be taken, normal values for men up to 8 mm. and for women up to 10 mm. are certainly safe. For the Wintrobe and Landsberg method any figure less than 10 mm. should be considered normal. Each method has advantages and disadvantages. For example, the Wintrobe tube is more difficult to fill and clean than the Westergren tube. If cell volumes are going to be determined anyway, then the Wintrobe tube has advantages over any other. Many workers consider the Cutler tube too short for ease of reading and accuracy of determination. Perhaps the best method, taking advantages and disadvantages into consideration, is that of Westergren, and the long tube probably automatically corrects for a number of the shortcomings of other methods and for the variations of the cell volume. It is likely that, if readings are made in terms of "fast," "moderate," and "slow," as much information will be imparted to the clinician as an actual reading in terms of millimeters of fall in any given time.

Answer.—As in all laboratory procedures, the conditions must be adhered to as originally described, controls should be determined, and normal values should be established for that laboratory. The discrepancy in normal values cited provides a good illustration. In the original Westergren method 4 parts of blood are added to 1 part of 3.8% sodium citrate solution; the normal ranges for men and women are 1 to 3 mm. per hour and 4 to 7 mm. per hour respectively. Most textbooks describe a technique in which 9 parts of blood are added to 1 part of the anticoagulant, resulting in enhanced rouleau formation with a greater fall of the red blood cells in the one hour period; this modification quotes the normal values as 0 to 15 mm. per hour (4 mm. average) for men and 0 to 20 mm. per hour (5 mm. average) for women. Some have altered the test by collecting the blood in dry oxalate mixtures (allowing the one blood specimen to be used for other determinations) and then diluting 4 parts of this blood with 1 part of the citrate solution; the stated normal range in this case is up to 10 mm. per hour for both sexes.

The correction for anemia does not depend on the size of the tube. The Westergren and Wintrobe-Landsberg methods both utilize tubes of 2.5 mm. bore, and only the latter is corrected (to a 47% hematocrit for men and a 42% hematocrit for women); the Cutler method (5 mm. bore tube) does not have a correction, yet the Rourke-Ernstene method (4 mm. bore tube) is corrected to a 45% hematocrit for both sexes. The sedimentation rate is corrected for anemia because anemic patients often exhibit

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

increased sedimentation rates, red blood cells diluted with the plasma of the same person will fall faster than undiluted cells, and women (having less red blood cells than men) have a faster sedimentation rate. The need of correction is questioned by many, since the methods of correction are arbitrary and crude; in some anemia (hypochromic microcytic anemia, sickle-cell anemia, and those forms with marked poikilocytosis) there is no increase in sedimentation rate, the degree of anemia is not always correlated with the elevation of the sedimentation rate, and many anemic patients with another pathological process have a normal sedimentation rate when the abnormal rate is corrected for the anemia. Because of this difference of opinion, the sedimentation rate should be reported as found (stating the method employed) and as corrected (stating the method of correction and the hematocrit); this will allow the physician to interpret the results as he chooses. The test is nonspecific and not diagnostic of any disease, the sedimentation rate being normal in many diseases. An abnormal rate indicates some pathological state rather than a functional disturbance and is, therefore, useful in differential diagnosis and in following individual cases.

The inquirer gives normal values for the Westergren method. The Wintrobe-Landsberg corrected normals are 0 to 9 mm. per hour (3.7 mm. average) for men and 0 to 20 mm. per hour (9.6 mm. average) for women; using the Hynes and Whitby correction (to a hematocrit of 45% for both sexes), the normal range is 0 to 10 mm. per hour. The normal values for the Cutler method are 2 to 8 mm. per hour (3 to 4 mm. average) for men and 2 to 10 mm. per hour (5 to 6 mm. average) for women. All the methods compare well when measured during the period of constant fall; each, however, has its protagonists depending upon such factors as the laboratory conditions, available personnel, number of manipulations, and dilution of blood. The most reliable methods are the Rourke-Ernstene and the five minute Cutler modification, which measure the maximal rate of fall and require multiple readings; their normals are 0.05 to 0.4 mm. per minute and 0 to 1 mm. per five minutes respectively. Because of the extra height of its tube and other factors, the one hour reading in the Westergren method is directly proportional to the settling velocity during the period of constant fall. The Wintrobe-Landsberg method is widely used in the United States, since the hematocrit, buffy coat, and character of the plasma can be studied with the same tube of blood.

INFECTIOUS MONONUCLEOSIS

To the Editor:—*In the hepatitis that is associated with infectious mononucleosis the following questions arise. 1. Have liver biopsy studies and long-range follow-ups been done to determine whether the liver shows any later signs of cirrhosis following the subsidence of the acute febrile episode? 2. How long do positive function tests (cephalin flocculation) persist? 3. If the liver and spleen are not palpable, is there any proved indication that activity should be limited following mononucleosis? 4. If clinically a patient, aged 21, after having a fairly severe febrile course of mononucleosis, does not feel debilitated, should his activities be restricted?*

M.D., California.

This inquiry was referred to two consultants whose respective replies follow.—Ed.

Answer.—This consultant is not familiar with any work definitely establishing the hepatitis of infectious mononucleosis as a forerunner of hepatic cirrhosis. In college students with infectious mononucleosis the cephalin flocculation and thymol turbidity tests are frequently abnormal three to four weeks after termination of the febrile period. At the end of six to eight weeks these tests are usually normal. A few do not return to normal until three months have elapsed. On the basis of these tests this consultant has never seen evidence suggesting that a case is progressing toward a chronic hepatitis. Contrariwise, these tests have been reported as abnormal in 4 of 12 children with infectious mononucleosis followed for seven months to two and a half years after the disease (*A. M. A. Am. J. Dis. Child.* 84:175 [Aug.] 1952). Even though the liver has never been palpable, the liver function tests often are abnormal at the time a patient is discharged from hospital. Several times a year a worsening or a delayed return toward normal of these tests is observed in students engaging in sports too early during convalescence. Less than ordinary activity is strongly recommended for any patient convalescing from infectious mononucleosis until the sedimentation rate and liver function tests are approaching normal. If there is any hepatomegaly, splenomegaly, or anemia, more stringent limitations would be in order.

Answer.—1. Clinical observations and autopsy and biopsy studies of the liver of patients with infectious mononucleosis indicate that the liver involvement in this disease does not compare in severity or potential danger with that seen in infectious hepatitis. No instance of death from liver failure or acute hepatic necrosis has been observed in patients with infectious mononucleosis. Morphological data indicate that the hepatic alterations in this disease consist chiefly of lymphocytic and mononuclear cell infiltration, but parenchymal necrosis is sparse and uncommon. While an occasional case of cirrhosis following infectious mononucleosis has been reported (*Am. J. Med.* 8:675, 1950) other etiological factors such as alcohol and malnutrition may have been of greater importance than the infectious mononucleosis in the pathogenesis of the cirrhosis. One is justified in concluding that cirrhosis is such a rare sequel of infectious mononucleosis that it is statistically unimportant. 2. Minor alterations of liver function tests may persist for months or even years; but since the hepatic dysfunction is of a benign nature, prolonged therapy or bed rest is not indicated (Spellberg, M. A., Diseases of the Liver, New York, Grune & Stratton, Inc., 1954, pp. 252-256). 3. If the liver and spleen are not enlarged and there is no undue anorexia or fatigability and no marked alterations of liver function tests, activity need not be restricted any longer than in nonhepatic febrile illnesses. 4. The fourth question is answered in 3. In the case mentioned, this young patient's activities should not be restricted anymore than if he were convalescing from a viral pneumonitis or any other febrile illness. Gradual resumption of activities should be undertaken after defervescence.

ERYTHEMA MULTIFORME

To the Editor:—*What is the treatment for erythema multiforme? A 72-year-old man has been getting attacks about once a year, usually in July or August. The first symptoms include severe itching and burning of the eyes (iritis). Within 24 hours there is dermatitis on the right wrist, dermatitis on the fingers, blisters on the glans penis, and ulcerations in the mouth. The most recent attack included exfoliation of the outer layer of the tongue, which is the first time this symptom occurred. The symptoms are usually self-limited—about three weeks. Hydrocortisone is used orally in the eyes and as a decongestant. Meticorten was not used.*

M.D., Pennsylvania.

Answer.—Erythema multiforme is a symptom complex rather than an etiological diagnosis. The cause of this condition varies, and treatment from the standpoint of prevention of further outbreaks, or even to treat intelligently the acute attack, would require study and identification of the underlying precipitating factors. Among the more common causes are bacterial or virus infection, or ingestion of foods or drugs to which the patient may react. A summer recurrence may suggest as a possible cause ingestion of a seasonal food or recurrence of some environmental factor associated with warm weather, such as pollen, plants, or molds that could be absorbed and induce the symptom complex. In the absence of establishing the cause, treatment is purely symptomatic and the following sometime prove helpful: (1) a mild saline cathartic such as milk of magnesia; (2) an antihistaminic given orally, such a tripelennamine hydrochloride (50 mg. every six hours) or chlorprophenpyridamine maleate (2 to 4 mg. three to four times daily); or (3) a broad spectrum antibiotic taken systemically, as for example, erythromycin (200 mg. each four to six hours). The hydrocortisone preparations such as given are also effective in affording temporary relief. Because of their side-effects, the local or topical use is to be preferred over their systemic use. A 1% concentration of hydrocortisone acetate in a water-soluble base is sufficient. If infection is present in the skin lesions, an ointment containing both an antibiotic and an adrenocorticone hormone may be useful, such as Neocortef ointment.

STONE IN GALLBLADDER

To the Editor:—*A 49-year-old woman suffers from slight indigestion. X-ray examination revealed a good functioning gallbladder with one peach-stone-sized calculus. Her mother died at age 70 years from a cancer of the gallbladder. Would you advise cholecystectomy, though the complaints at present are negligible?*

Hans M. Magnus, M.D., Cambria Heights, Queens, N. Y.

Answer.—While the presence of a calculus in the gallbladder probably increases slightly the liability to subsequent formation of cancer of the gallbladder, this is not sufficiently great to be in itself an indication for cholecystectomy. The presence of a normally functioning gallbladder indicates that in this case the calculus has not produced any marked damage to the mucous membrane of the gallbladder or to its muscular wall. The calculus is probably a solitary cholesterol stone that has formed in an aseptic gallbladder and is, apparently, not causing stasis of bile. While many excellent surgeons would, undoubtedly, advise cholecystectomy in this situation as a prophylactic against the subsequent development of more serious gallbladder disease, it is certain that there are also many excellent surgeons who are going about with just such a gallstone and who do not themselves choose to have a cholecystectomy. Since in the present instance the complaints are negligible, it would appear unwise to subject the patient to the hazard of a major surgical operation.

RETINITIS WITH MACULAR EDEMA

To the Editor:—*A patient has had three episodes of retinitis with macular edema, and the last episode is still active. The first attack started in 1949 at age 35. Physical and laboratory studies including x-ray of the skull, sinuses, teeth, and chest, prostatic smears, blood cell counts, sedimentation rate determinations, urine studies, Wassermann test, blood sugar level studies, and blood chemistries have all been negative. On the two previous occasions, the patient spent several weeks in the hospital, the first time having essentially symptomatic treatment, the second stay receiving daily injections of alternating intravenously given typhoid vaccine and slow drip administration of corticotropin (ACTH). The first attack resulted in complete recovery (the right eye only was affected during this siege). The second episode affected both eyes, but after several months the right eye fully recovered, while the left went from 20/15 to 20/15 minus 3. The present episode is being treated with meticorten 30 mg. daily, large doses of vitamin B complex orally, and potassium chloride (1 grain [60 mg.] three times daily). There has been no improvement one week after therapy. A recent physical examination and laboratory studies revealed nothing other than the retinal and macular edema. An otolaryngologist says that although the tonsils were removed during childhood, the right fossa reveals a small tag and the left tonsil has regrown. From the left tonsil he can express "cheesy purulent material." The patient had a cervical adenitis on the right several months ago that improved with four days of treatment with achromycin. The question is whether to do a tonsillectomy now or to wait in the hope the edema will subside without tonsillectomy.*

M.D., Pennsylvania.

Answer.—The patient apparently is in the first stage of a heredomacular degeneration of the Kuhnt-Junius type. During secondary inflammatory episodes tonsillar removal or similar surgical procedures may be followed by ocular aggravation due to dissemination of toxic material into the subnormal macula. If possible, temporizing tonsillar treatment with local silver nitrate applications and the bodily administration of antibiotics with or without sulfas is advisable until the ocular reaction has entirely subsided. Then tonsillar removal may help prevent or reduce future retinal inflammatory attacks. Adrenocortical and supportive treatment as described probably reduces the retinal reaction and therefore its residue if not unduly prolonged. In that case healing may be delayed and ultimate fibrosis increased. There is now no local or bodily treatment that will positively cure the disease or prevent its possible progressive degenerative tendency. Much can be done, however, to prevent or reduce secondary inflammatory attacks by maintaining the highest possible biophysical and biochemical level of well-being. Metabolic abnormalities and autonomic imbalance are important factors in precipitating inflammatory attacks.

PATIENTS USING RUBBER URINALS

To the Editor:—*An elderly man wearing a urinal complains of marked edema of the penis caused apparently by the alkaline reaction of the urine in the pouch. The urinal is made of rubber; no other material of like softness seems to be available at present. The urine when passed is acid due to administration of an adequate number of ammonium chloride tablets, with or without methenamine. The urine turns alkaline quickly after accumulating in the pouch. What acidifying agent can be used in the bag? A penis clamp can be tolerated for about an hour, when it causes marked edema.*

R. J. Kent, M.D., Savannah, N. Y.

Answer.—Irritation with edema of the penis is a common complication in patients wearing a rubber urinal. In most cases, the irritation is caused by the rubber rather than the alkaline reaction of the urine in the pouch. A new type of urinal has been devised made of latex rubber, which usually is more comfortable and is better tolerated. If this apparatus does not relieve the symptoms, possibly the best thing would be to have the patient use a disposable absorbent material in a plastic bag. When the absorbent material is saturated, it can be disposed of and replaced with fresh material.

SCARLET FEVER AND ACUTE RHEUMATIC FEVER

To the Editor:—*Is there any causal relationship between scarlet fever and acute rheumatic fever? Does rheumatic fever occur as a complication of scarlet fever? Does it rarely do so, or does it fairly frequently do so?*

Raymond C. Scannell, M.D., Denver.

Answer.—The exact etiology of rheumatic fever continues to be in doubt. Streptococci have long been associated with rheumatic fevers. For many years scarlet fever in particular has been considered as a possible inciting cause; however, all rheumatic fever patients do not have a history of scarlet fever. Moreover, it has been claimed that rheumatic fever may occur when there is bacteriological evidence of no preceding streptococcic infection. Rheumatic fever is not regarded ordinarily as a complication of scarlet fever. Nevertheless, statistics in the past have shown that the incidence for each of the diseases has risen and declined at about the same time. Streptococcic infections are now at a low point; therefore rheumatic fever should be less prevalent. Hereditary susceptibility has been considered an important factor.

PUS IN THE URINE

To the Editor:—*A patient had pus in urine for about two years. He found this accidentally, as it did not cause trouble, and has tried Gantrisin, Aureomycin, Achromycin, and Erythromycin with no improvement. He is sensitive to penicillin. A culture made from the urine was sterile. He has a large stone in the pelvis of the right kidney. He had an exploratory operation on the left kidney two and one-half years ago, and biopsy showed it to be not malignant but apparently congenitally deformed. I would appreciate help in determining a course of action.*

M.D., Michigan.

Answer.—To find the source of pyuria, the patient should be subjected to a cystoscopic examination, including ureteral catheterization of both kidneys and an estimate of differential renal function. In all probability the stone in the right kidney is causing the pyuria. There would be no object in continuing the use of antibiotic drugs until the stone is removed. It would be impossible to say whether a nephrectomy or nephrotomy would be indicated until the examinations have been completed. A renal stone may be silent symptomatically but is seldom present for long without pathological changes in the kidney.

A NUTRITIONAL PROGRAM FOR PROLONGATION OF LIFE IN CORONARY ATHEROSCLEROSIS

Lester M. Morrison, M.D., Los Angeles

For the past decade, atherosclerosis has no longer been regarded as the inevitable result of age or the "wearing out" of the arteries but rather as a disorder of lipid and/or lipoprotein metabolism.[1] This occurs in young people and is known as a process beginning in early childhood.[2] It is a paradox that with the birth of the infant, the process of aging or death thus sets in. In considering the difficult problem of treatment for atherosclerosis of the coronary arteries in particular, recognition has now come of some six factors that are most frequently incriminated in the development and treatment of the disease. Briefly stated they are: (1) dietary factors; (2) reduction of body weight; (3) certain agents having pharmacological properties, such as lipotropic substances, female sex hormones, anticoagulating agents, and tobacco; (4) anatomic factors of stress and strain at certain points in the arterial walls; (5) hereditary or familial tendencies; and (6) physical exercise and emotional factors. A report follows of over eight years of controlled studies of certain aspects of the first three factors cited above.

DIETARY FAT AS A CAUSE

The incrimination of dietary fat as the cause of human arteriosclerosis or atherosclerosis dates largely from World War I. After the British blockade of Germany during that war it was noted extensively by German pathologists and clinicians that the incidence of deaths and sickness from coronary and cerebral vascular atherosclerosis fell sharply. After that war, with the lifting of the food blockade and the resumption of the customary fat intake in the diet, the incidence of deaths and morbidity from these diseases rose again to prewar levels in Germany.[3] During World War II history repeated itself as regards the relationship of dietary fat and the incidence of coronary and cerebrovascular arteriosclerosis and/or atherosclerosis. This time the various Scandinavian governments supplied the information that, when fat in the diets of the population had to be reduced to a minimum because of the scarcity of dietary fats, the death and sickness rate from atherosclerosis was likewise reduced to a minimum. As soon as the war ended and dietary fat once again became plentiful, the mortality rate and morbidity rates from coronary and cerebrovascular disease promptly soared to prewar levels and even began to surpass them.[4]

More recently, additional information corroborating these findings was obtained from American military studies such as those of Enos [5] and others. As a consequence, numerous investigations began into the role of lipid metabolism in the production of human and animal atherosclerosis.[6] It was well established that atherosclerosis induced by feeding excessive quantities of cholesterol and fats in the diet could easily be produced in rabbits, rats, dogs, and monkeys.[7] Objections to the validity of any concepts about atherosclerosis derived from such studies were numerous due mainly to species differences. Consequently it was decided that human subjects would provide the soundest approach to the question of any relationship between dietary fats and cholesterol in the production of atherosclerosis. This de-

cision to use human subjects stemmed from the now overwhelming mass of evidence that atherosclerosis was no longer the inevitable result of age or a "wearing out" or "rusting" of the arteries. I have approached this problem as a disorder in lipid or lipoprotein metabolism, which takes its toll of young adults as well as older persons. This view is borne out by the findings of various authors such as Dock,[1a] myself,[8] and others that the atherosclerotic process in the American adult is already well developed when the individual is in his 30's.

STUDY OF DIETARY FAT INTAKE

Accordingly, in 1946, I [9] began the study of 100 patients to determine the relationship of dietary fat intake to the incidence of atherosclerosis. These patients had proved cases of coronary thrombosis with myocardial infarction and had survived their initial attack. This particular disease was selected because it had been demonstrated by various observers [10] that in 90% or more of the patients with coronary thrombosis and myocardial infarction the cause of the disease was atherosclerosis of the coronary arteries. Thus a direct approach to human atherosclerosis was available. The 100 patients described above were divided into two groups of 50 patients each. Each group consisted of unselected patients with proved myocardial infarction who survived their initial attack and whose condition was uncomplicated by other disease such as hypertension, diabetes mellitus, nephritis, thyroid disease, xanthomatosis, or other conditions in which a complicating metabolic disorder was present. The two groups of 50 patients each consisted of a control group in which no dietary restriction of fat was imposed and a treated group in which the dietary fat was restricted from 20 to 25 gm. of fat daily. In both groups any customary medicaments of a supportive character were given when indicated.

Survival Rates in Patients with Coronary Thrombosis and Infarction After Eight Years

No. of Cases	Deaths	Survival
Normal Prethrombosis Diet		
50	38 (76%)	12 (24%)
20-25 Gm. Fat-Cholesterol Intake		
50	22 (44%)	28 (56%)

After three years of observation of these two groups, I used the criterion of mortality rate only to test the validity of the concept that dietary fat was related directly to the production of atherosclerosis in the human. Mortality rates in these cases appeared to offer final conclusions regarding the arrest or regression of the atherosclerotic process and did not involve objectionable features such as interpretations of subjective symptoms in patients or similar problematical data. At the end of the three year study period [9] it was found that 35 of the 50 patients in the control group survived, 15, or approximately one-third, having died of cardiac disease, mostly recurrent coronary thrombosis. In contrast, 43 of the 50 patients who were dietetically treated (through dietary fat restrictions) survived, 7 of them having died of cardiac disease, mostly coronary thrombosis with myocardial infarction. These cases were too few to be of statistical significance, yet they did suggest that dietary fat restriction directly retarded the progress or development of atherosclerosis of the coronary arteries.

RESULT OF EIGHT YEAR FOLLOW-UP STUDY

Since the above studies were begun in 1946, eight years have elapsed in which the original 100 patients with coronary atherosclerosis have been followed. The original 50 dietetically treated patients and their families were continually supervised as regards adherence to the diet. These patients originally assured their full coöperation; patients who could not be relied upon for complete cooperation were dropped from this study at the outset. Cooperation in adherence to the diet appeared to be assured by the statements of the families involved as well as by the patients themselves. Full cooperation from patients resulted in falls in serum lipid levels and decreases in body weights. In the three-year follow-up of these 50 dietetically treated patients, it was noted that the average fall in weight was 21 lb. (9.5 kg.) for males and 17 lb. (8 kg.) for females. Total serum lipid levels fell from 840 mg. per 100 cc. before treatment to 571 mg. after treatment; total serum cholesterol levels fell from a pretreatment and mean level of 312 mg. to 220 mg. per 100 cc.; and neutral fat fell from 236 mg. to 120 mg. per 100 cc.

After eight years of observation the following number of deaths occurred in both groups of patients as noted in the table. Of the original 50 control patients who had coronary thrombosis and myocardial infarction, only 12 were living; 38 had died mainly of cardiovascular disease. Of the original 50 dietetically treated patients on low-fat, low-cholesterol diets, 28 were living; 22 had died mainly of cardiovascular disease. The mean age for the surviving dietetically treated patients with coronary disease was 68 years and that for the control or nondietetically treated patients was 70 years, the age range for both groups being 40 to 78 years of age. Of the 28 surviving treated patients, 6 were females and 22 were males. Of the 12 surviving control patients, 4 were females and 8 were males.

TYPE OF NUTRITIONAL PROGRAM

As for the diets of both control and dietetically treated groups, as originally noted,[9] the dietary fat content each day for the control group was judged to range from 80 to 160 gm. of fat, with an estimated range of cholesterol intake of from 200 to 1,800 mg. daily. The dietetically treated group consumed an estimated 20 to 25 gm. of fat daily, with a cholesterol intake estimated at 50 to 70 mg. In this group, the caloric intake averaged 1,600 calories comprised of approximately 225 gm. of carbohydrate and 120 gm. of protein. The diet prescribed included a vitamin A content of 9,753 I. U., 2.48 mg. of riboflavin, and 140 mg. of ascorbic acid, all within the normal daily intake limit. In addition, a supplementary vitamin capsule that more than doubled the daily dietary vitamin intake was prescribed to be taken daily. The mineral content of the diet was similarly normal, containing approximately 1.009 gm. of calcium, 1.792 gm. of phosphorus, and 0.0222 gm. of iron. In order to provide additional protein in the diet, a natural supply of vitamin B complex, a minimum of 2 oz. (60 gm.) of whole-wheat germ and 8 gm. of powdered, flavored brewer's yeast was prescribed with fruit and skim milk at least once a day. This combination also utilized the well-known therapeutic action of the lipotropic factors contained in choline, inositol, methionine, cyanocobalamin, and vitamin B_6 in the prevention and treatment of atherosclerosis in experimental animals as well as in patients with coronary artery disease.[11] These lipotropic factors are potentiated by the high-protein, low-fat diet.

No significant further changes in weight occurred during eight years for either male or female patients in the treated group after the mean pretreatment weights for males dropped from 166 lb. to 145 lb. (75 to 66 kg.) in the three year reports [9] and the mean pretreatment weights for females dropped from 141 lb. to 124 lb. (64 to 56 kg.) after three years of dietary treatment. The control patients' weights, as originally noted, did not appear to undergo any significant alteration. Medication in both groups of patients was usually similar and, when indicated, consisted of digitalis, aminophylline, glyceryl trinitrate (nitroglycerin), or sedatives, as needed by the patients, depending upon their cardiac condition.

MORTALITY RATES AND CAUSE OF DEATH

As noted in the table, if the mortality rates of both groups are estimated percentagewise, they are as follows: After eight years with no treatment, of the 50 patients in the control group who had coronary disease, 12 survived, a survival rate of 24%. After eight years of dietary treatment, of the 50 patients who had coronary disease, 28 patients survived, a survival rate of 56%, or more than double that of the control patients.

A breakdown of the cause of death in each group of patients after eight years of observation indicated that the mortality rates of the patients with coronary disease in the control group are comparable to those described by various authorities.[12] In the control or nontreated group, of the 38 patients who had died, death was due to cardiovascular disease in 22 cases and to extracardiac diseases, including cerebrovascular, in 8 cases. In eight patients death was due to causes that could not be determined. In the patients treated through the nutritional program, of the 22 patients who had died, death was due to cardiovascular disease in nine cases and to extracardiac diseases in eight cases. In five patients death was due to unknown causes.

OVERWEIGHT AS A FACTOR

A significant factor in the evaluation of results obtained with restricted dietary fat intake in this group of patients is weight reduction. As noted in a previous publication [9] and in this one, a weight loss tantamount to some 15% of total body weight occurred after three years of dieting in the treated group of patients with coronary disease. It was originally pointed out by Hippocrates [13] and more recently by the statistical divisions of various life insurance companies and by numerous authorities [1a] that overweight is an important factor in increasing the mortality rate in coronary and cerebrovascular disease. American malnutrition is becoming widespread in the sense that excessive calories are consumed, with an abnormal concentration on carbohydrate and fat intake, and there is loss of essential nutrients from processing refinements and the cooking of foods. As a consequence, "oily dropsy," [1a] or overweight, results and prohibits the ideal weight that patients, particularly those with coronary disease, should maintain for their body build at maturity.

After three years of dietary fat restriction, the dietetically treated patients with coronary disease showed no further significant weight loss or gain. For the five years after this stabilization of weight in the treated group of patients, an appreciable difference in the mortality rates between the two groups of patients is apparent and is not further influenced by additional weight loss or gain. It should also be considered that the dietetically treated group of patients at the end of three years approximated ideal or more normal weight levels and so was a more favorable group of patients to treat than the control patients, whose weights were comparatively unaltered through the period of observation.

CORROBORATIVE FINDINGS OF NEW STUDIES

Since the inception of these studies, new information has been collected by various investigators that now directly correlates the relationship of high-fat dietary intake with high mortality rates from degenerative heart disease and vice versa.[14] The recent studies of American and Oriental soldiers in Korea [5] have served to point sharply to the correlation of dietary fat intake and the incidence of coronary atherosclerosis in both American and Oriental soldiers. This may be significantly linked to the startling increase in both coronary atherosclerosis and the fat and caloric content of the American diet. A description of the moderately high-protein, low-fat, low-cholesterol diet utilized in this study is similar to the diet originally prescribed eight years ago at the outset of these studies by me.[15]

It is of interest to note that a frequent observation in the group of patients treated by the nutritional program described here was a sense of optimism, well-being, and good spirits; increased exercise tolerance and increased working capacity, with decrease or disappearance of anginal symptoms, occurred in certain cases. This study suggests the value of similar surveys utilizing larger numbers of cases for statistical evaluation. In this way the incorporation of a nutritional program as described here can be considered for therapeutic or preventive uses in medical practice.

SUMMARY AND CONCLUSIONS

One hundred patients with proved coronary thrombosis and myocardial infarction were observed over an eight year period of time. The patients were divided into two groups of 50 patients each. One group was the control group of patients who maintained their prethrombosis diets and weights. The treated group of patients was studied and compared as to survival rate resulting from a nutritional program of a low-fat, low-cholesterol diet that was moderately high in protein, supplemented by certain vitamins, and accompanied by a significant loss in weight. After eight years of observation, of the 50 patients in the control or nontreated group, 12 patients had survived, a survival rate of 24%. Of the 50 patients treated through the above nutritional program, 28 patients had survived, a survival rate of 56%. It was noted that the survival rate of postcoronary patients, i. e., with proved coronary atherosclerosis, on a specific nutritional program was more than 100% greater than that of postcoronary patients in a control group who adhered to the typical American diet.

USE OF EXTERNAL ELECTRIC PACEMAKER IN CARDIAC ARREST

Paul M. Zoll, M.D., Arthur J. Linenthal, M.D., Leona R. Norman, M.D., Milton H. Paul, M.D.
and
William Gibson, M.D., Boston

Cardiac arrest presents a critical problem in four different types of clinical situations: (1) in Stokes-Adams disease; (2) during reflex vagal stimulation; (3) during treatment with cardioactive drugs; and (4) during various diagnostic and therapeutic procedures, particularly during anesthesia. It requires emergency resuscitation for which the desperate and often ineffective measures of cardiac puncture, intracardiac drugs, and thoracotomy with cardiac massage have been the only therapy heretofore available.[1] We have developed a new therapeutic approach to the problem of cardiac arrest[2]: an externally applied cardiac pacemaker that stimulates the heart electrically, terminates ventricular standstill, and maintains an externally paced ventricular rhythm for as long as necessary. The electric stimulator functions like a natural intracardiac pacemaker but is under complete external control. The instrument is portable, easily applied, and clinically practicable.

STOKES-ADAMS DISEASE

Stokes-Adams disease consists of attacks of cerebral ischemia due to very slow idioventricular rates, ventricular standstill, ventricular tachycardia, or ventricular fibrillation in patients with atrioventricular heart block.[3] The attacks are manifested by dizziness, syncope, prolonged unconsciousness, and convulsions, and they may end in death. The cardiac origin of such seizures becomes clear when circulatory arrest is observed during an attack; the diagnosis of Stokes-Adams disease should be suspected when heart block of any degree is observed between attacks.

We have now resuscitated 27 patients from Stokes-Adams attacks with the electric pacemaker. Attacks due to very slow idioventricular rates were observed in 8 patients and to ventricular standstill in 24 patients; these episodes of cerebral ischemia were all terminated immediately by electric stimulation. This dramatic effect was observed countless times. Stokes-Adams attacks due to ventricular tachycardia or fibrillation were seen in 14 patients; none of these was stopped by stimulation. In five patients, however, with frequent attacks due to multifocal ventricular tachycardia or fibrillation, continued external stimulation prevented their recurrence. Stimulation was continued after resuscitation in 22 of the patients for periods as long as 109 hours. Continued stimulation was necessary in them to maintain effective circulation, because of persistent absence of spontaneous ventricular beats or because of recurrent ectopic ventricular activity.

The figure shows electrocardiograms from one of these patients and demonstrates effective external stimulation of the heart. The intensity of the electric stimuli (E) was progressively increased until ventricular responses (V) were produced (figure, *A*). Three spontaneous idioventricular complexes (cycle length 2.04 seconds) are seen during ineffective stimulation; during effective stimulation at a faster rate (cycle length 1.11 seconds), they are suppressed. When stimulation was stopped, the spontaneous ventricular pacemaker reappeared after a pause of 4.64 seconds and regained its previous rate within three beats (figure, *B*). Each stimulus (E) produced a ventricular response (V). Each electrocardiographic ventricular response depended upon an electric stimulus as shown by the constant relationship at widely varying rates of stimulation (figure, *C*). During a test period of 5.5 seconds, no stimuli were applied (figure, *D*). No spontaneous ventricular contractions oc-

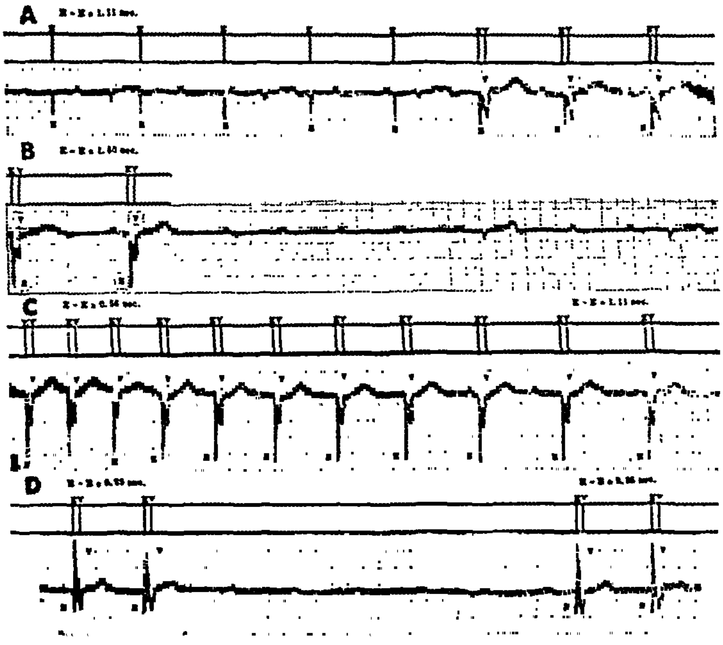
curred during this interval, and the patient lost consciousness. The independent atrial rhythm continued. Resumption of stimuli immediately gave ventricular responses, and the patient revived at once.

The patient was a 71-year-old woman who usually showed complete atrioventricular block, but partial block and normal sinus rhythm were occasionally observed. She suffered frequent and severe syncopal attacks, usually due to ventricular standstill but occasionally due to bursts of ventricular fibrillation. On eight occasions in two months, prolonged stimulation for periods ranging from 6 to 48 hours was necessary to maintain adequate circulation until a spontaneous sustained idioventricular pacemaker reappeared. The intervals of stable rhythms between these periods of stimulation varied from two hours to 19 days. She has now survived for 22 months since the initial resuscitation by the cardiac pacemaker. Her present condition is satisfactory, and she shows no deleterious effects on her mental or cardiac function as a result of either the prolonged stimulation or the syncope. She has had no attacks for 20 months.

In the 27 patients with Stokes-Adams disease resuscitated with the external electric pacemaker, survival is dated from the time that spontaneous ventricular activity returned after the first therapeutic application of stimulation, whether it was used briefly for resuscitation or continuously for maintenance of circulation. Ten patients, four of whom are still alive, survived 1 to 29 months. Duration of stimulation for these patients varied from a few seconds to 109 hours. Of the remaining 17 patients, in whom duration of stimulation was a few seconds to 108 hours, 8 survived 1½ to 16 days, 5 survived 1 to 11 hours, and 4 did not survive the initial period of stimulation.

Twenty-three patients are now dead. Eighteen died of Stokes-Adams attacks because the electric pacemaker was not applied during the fatal attack, because the attack was due to ventricular tachycardia or fibrillation, or because of irreversible cerebral damage due to cardiac arrest before electric stimulation was applied. The remaining five patients died of cardiac tamponade from multiple cardiac punctures, of acute myocardial infarction, of acute bacterial endocarditis, and suddenly after a 10 month interval without syncope.

On the basis of these experiences we have formulated a program for the treatment of a patient with Stokes-Adams attacks. If the patient is seen during a seizure, the external electric pacemaker should be applied at once. If it is not immediately available, one should slap the chest, then puncture the heart with a needle, and finally inject epinephrine into a cardiac chamber. After resuscitation, if sustained, adequate, spontaneous ventricular activity does not reappear, the patient may be kept alive by the external pacemaker. This external stimulation must be continued until intrinsic ventricular activity reappears spontaneously or is aroused by drugs like epinephrine, given preferably by controlled intravenous infusion beginning at 4 mcg. per minute. To maintain blood pressure, arterenol should be given.



Lead aVF; standardization half-normal (1 mv. equals 5 mm.). *A*, interruption of idioventricular rhythm by faster externally paced beats; *B*, resumption of idioventricular rhythm after external stimulation; *C*, effective stimulation at varying rates; *D*, ventricular standstill during temporary interruption of stimulation.

The prevention of recurring Stokes-Adams attacks is a third major problem. When the idioventricular rate is too slow (below 30 per minute), ephedrine sulfate and isopropylarterenol are often useful for long-term maintenance of heart rates between 30 and 45 beats per minute. When they are due to varying atrioventricular conduction, atropine and ephedrine should be tried. When the attacks are due to recurrent ventricular tachycardia or fibrillation, ephedrine again may reduce ectopic activity by increasing the basic ventricular rate; quinidine and procainamide are contraindicated in these patients.

REFLEX VAGAL ARREST

Episodes of cerebral ischemia due to ventricular standstill or fibrillation also occur in patients without Stokes-Adams disease. Certain of these episodes, as in the carotid sinus syndrome, are usually transitory and are clearly due to reflex vagal stimulation. The distinction between Stokes-Adams disease and reflex vagal standstill is of clinical importance because of differences in the course, prognosis, and treatment of each condition. This distinction ultimately depends upon the presence or absence of atrioventricular block between attacks.[3]

External electric stimulation was effective repeatedly in resuscitating three patients with ventricular standstill due to reflex vagal stimulation. In all three, episodes of complete heart block and ventricular arrest repeatedly interrupted normal sinus rhythm abruptly, producing syncope and convulsions. The precipitation of such episodes by carotid sinus pressure and their disappearance after the administration of atropine sulfate established their reflex vagal origin. More than 100 times, in these patients, external electric stimulation terminated ventricular standstill and restored an effective circulation.

STANDSTILL DUE TO DRUG INTOXICATION

A third type of cardiac arrest occurs as a result of depression of cardiac rhythmicity due to drug intoxication. We have observed two patients with attacks of syncope due to digitalis. With the occurrence of sinoatrial block, cardiac activity was maintained by atrioventricular nodal or ventricular pacemakers; intermittent failure of these pacemakers resulted in periods of ventricular standstill lasting as long as one minute. External electric stimulation resuscitated the patients immediately several times. With recession of digitalis effect, seizures stopped. Two patients with ventricular standstill after intravenous administration of procainamide in the treatment of ventricular extrasystoles and tachycardia were also resuscitated promptly by the external electric pacemaker.[4] Experimentally we have observed that the electric pacemaker also produces effective beats during marked cardiac slowing due to quinidine.

UNEXPECTED CIRCULATORY ARREST

In addition to patients with Stokes-Adams disease and reflex vagal standstill, circulatory arrest may also occur in a third group of patients. Young, healthy individuals without heart disease may develop circulatory arrest unexpectedly, while undergoing various diagnostic and therapeutic procedures, particularly under anesthesia. Though infrequent, each such accident is a dreadful catastrophe. The commonly recognized mechanisms of unexpected circulatory arrest are ventricular standstill or fibrillation; standstill is the usual cause (88% according to Stephenson and co-workers [5]). Reflex vagal stimulation appears to be a frequent precipitating factor.[5]

Electric stimulation has been effective in a number of cases of unexpected circulatory arrest. In two cases of ventricular standstill associated with cardiac surgery, one observed by us [2c] and one reported by Bailey and co-workers,[6] effective ventricular beats were produced by external or direct stimulation; despite this temporary cardiac resuscitation, however, both patients died because of unsuccessful cardiac surgery. Three other patients recovered completely after external electric cardiac resuscitation. Darsie and Dammann [7] reported a patient who, after cardiac surgery, developed complete heart block with a slow idioventricular rhythm and then persistent ventricular standstill. External stimulation was necessary for 63 hours to maintain an adequate circulation; normal atrioventricular conduction then returned and the patient recovered completely. In a second patient, reported by Douglas,[8] circulatory arrest occurred suddenly during a pericardicentesis; within 2 minutes external electric stimulation was applied and resuscitated the patient promptly. The third patient was reported to us by Davis.[9] Cardiac arrest occurred unexpectedly at the end of a long abdominal exploration. External electric stimulation of the heart was applied after 2½ minutes of arrest and resuscitated the patient promptly. Standstill recurred three times in the next two hours; each time the electric pacemaker restarted the heart promptly and the patient recovered completely.

We attempted resuscitation with the cardiac pacemaker unsuccessfully (after delays of a few minutes to two hours) in eight patients who developed circulatory arrest unexpectedly during jugular puncture, intravenous pyelography, bronchography, endotracheal intubation, cardiac catheterization, cholecystectomy, hipnailing, and cardiac surgery. These failures show that the problem of unexpected circulatory arrest is twofold. First, effective ventricular beats cannot be stimulated during ventricular fibrillation. Second, the responsiveness of the heart to stimulation diminishes progressively with continued anoxia. The time interval between circulatory arrest and the resumption of effective ventricular output must be brief, probably less than 3 or 4 minutes, if cerebral and cardiac function is to return unimpaired. Avoidance of excessive delay depends upon immediate recognition of the circulatory arrest and immediate institution of a prearranged program for resuscitation.

TREATMENT OF UNEXPECTED CIRCULATORY ARREST

Crucial delay in recognizing the onset of arrest would be avoided by a practical monitoring device to signal immediately the cessation of circulation. Ideally, such an alarm system should be simple and cheap enough to allow its routine application to all patients during anesthesia. Time is so vital after the onset of circulatory arrest that the anesthetist should announce its passage at 10 or 15 second intervals until circulation has been restored.

Since ventricular standstill is the more frequent cause of circulatory arrest, treatment for standstill should be instituted immediately unless the mechanism is known to be fibrillation. Although electrocardiographic identification of the cardiac mechanism is useful, treatment should not be delayed to obtain a tracing but external electric cardiac stimulation should be applied at once. While awaiting the electric pacemaker, one should stimulate the heart mechanically by slapping the precordium forcefully, by cardiac needle puncture, or by cardiac massage through the diaphragm when the abdomen is open. These measures are simple and immediately available but are frequently ineffective. If the electric pacemaker is close at hand and if the personnel are familiar with its use, it can be applied within 30 to 40 seconds. Auxiliary measures such as artificial respiration with oxygen, blood transfusion, and vasodepressor drugs may be necessary to maintain an adequate blood flow.

If the initial mechanism is ventricular fibrillation, or if the cardiac pacemaker fails to resuscitate the patient within one minute from the onset of arrest, the chest must be opened promptly and the heart massaged. If ventricular fibrillation persists in spite of effective massage, defibrillation should be attempted. Drugs, such as potassium chloride, procaine, or procainamide, may be injected into the heart, or countershock (60 cycle A. C., 120 to 150 volts, 0.1 second) may be applied across large electrodes on the heart.

Ventricular standstill may persist despite effective massage, may recur after massage, or may follow defibrillation; the electric pacemaker may then be applied directly to the heart and epinephrine hydrochloride (0.1 to 0.5 ml. of 1:1,000 aqueous solution) may be injected into the left atrial or left ventricular cavity. If resuscitation is successful, the patient must be under constant observation for two or three days, because arrest may recur. A monitor of the cardiac activity should be used to signal immediately the cessation of circulation, and the electric pacemaker should be attached and ready for instant use.

SUMMARY

A method of external electric stimulation has been developed that will arouse the heart from ventricular standstill and will maintain effective, externally paced beats for as long as necessary. It has been used successfully in the treatment of cardiac arrest occurring in Stokes-Adams disease, during reflex vagal stimulation, during treatment with cardioactive drugs, and during various diagnostic and therapeutic procedures.

ADDENDUM

Since submission of this paper, four additional patients have been resuscitated successfully from unexpected cardiac arrest.

TREATMENT OF ACUTE INFECTIOUS HEPATITIS IN THE ARMED FORCES

ADVANTAGES OF AD LIB. BED REST AND EARLY RECONDITIONING

Prior to World War II, the treatment of acute infectious hepatitis, or catarrhal jaundice as it was then frequently called, was the same as for other viral diseases: rest was prescribed during the acute phase but not enforced after the patient felt well and jaundice had begun to subside. During World War II, it was noted that relapses seemed to be associated with early ambulation, and, in addition, in three controlled studies [1] it was shown that patients treated with a high-protein diet and strict bed rest had a shorter duration of hospitalization than those on a regimen of ad lib. rest and ad lib. diet. Emphasis was placed on an exercise tolerance test as a means of detecting harmful residual activity of the disease.[2]

As a result of these studies, there has been general agreement for the last 10 years that rest in bed should be strict and should be continued as long as the patient has symptoms, or a tender, enlarged liver, or the liver function tests are abnormal. As a direct consequence of these ideas, the average duration of hospitalization of military personnel with infectious hepatitis increased from an average of 30 days during World War II to 60 days in the period just before the Korean war.[3] The average patient was disabled for a week before hospitalization and required two to three weeks of reconditioning before he could return to duty. Thus, the total duration of disability surpassed 80 days.

This drain on military manpower, along with more recent observations [4] suggesting that strict bed rest might not be as essential as heretofore thought, emphasized the need for a controlled study to determine the safety of a more liberal regimen of rest and less prolonged hospitalization. The recent epidemic of viral hepatitis among American military personnel serving in the Far Eastern Theater of Operations and the establishment in 1950 of a hepatitis treatment center at the United States Army Hospital, Kyoto, Japan, afforded an excellent opportunity to reinvestigate the effects of rest and diet on the course of the disease. The present report is a summary of studies conducted under the auspices of the commission on liver disease of the Armed Forces Epidemiologi-

EXPERIMENTAL DESIGN AND METHODS

Patients were admitted to one of the treatment groups by a system of randomization designed so that the medical officer admitting a patient to the study did not know at the time of acceptance what treatment the patient was to receive. The 126 patients admitted to the two strict bed rest wards were required to stay in bed at all times, except for one trip to the bathroom per day and a shower twice a week. Verification of adherence to this schedule was provided by inspection of the ward four to six times daily, at irregular intervals, throughout the period of hospitalization. On the two ad lib. rest wards no effort was made to control the activity of the 127 patients, except that they were required to remain on the ward and to rest in bed for one hour after each meal. They were, however, allowed to remain in bed if they felt sick. The degree of activity indulged in was recorded each day.

Results of Treatment of Patients with Acute Infectious Hepatitis

	First Study		Second Study	
Bed Rest	Strict	Ad Lib.	Ad Lib.	Ad Lib.
Reconditioning	Delayed	Delayed	Early	Delayed
Total patients	126	127	95	94
Duration of acute illness, days	30	28	34	28
Patients with early sulfobromophthalein relapses, %	8	6	2	5
Duration of hospitalization, days*	64	63	51	47
Total patients given complete follow-up examination	46	49	40	41
Follow-up examination findings				
Significant symptoms, %	10	12	2	2
Palpable livers, %	12	12	23	19
Liver tenderness, %	12	14	19	0
Abnormal				
Serum bilirubin, %	0	6	0	7
Sulfobromophthalein retention, %†	2	6	7	5
Thymol turbidity, %	2	8	5	5
"Abnormal" patients at time of follow-up, %‡	13	16	10	5
Rehospitalized after discharge, %§	11	6	2	0

* Including time at reconditioning center.

† All abnormal sulfobromophthalein retentions were between 5 and 10%.

‡ "Abnormal" patients were determined by a point score system set up before the study. Thus each category of abnormality, including symptoms, individual physical signs, and liver function tests, was given 1 or 2 points according to clinical significance, and patients with 3 or more points were termed "abnormal."

§ For complaints possibly but not necessarily related to previous hepatitis. No patients had known relapses with jaundice.

In a second study all patients were treated with ad lib. rest, while varying dietary regimens were being compared. In a group of 95 patients, who were assigned at random on admission, strenuous physical reconditioning was started as soon as the total serum bilirubin level was 1.5 mg. per 100 ml. or below and the sulfobromophthalein retention 5% or less in 45 minutes. Ninety-four had delayed reconditioning and remained in the hospital an additional eight days as controls. The early group received an extra week of reconditioning so that the total observation period would be the same for each group. Clinical examinations and liver function tests were performed on all patients twice a week. The sulfobromophthalein test, with 5 mg. administered per kilogram of body weight, was performed once weekly from the time the total serum bilirubin level was 1.5 mg. per 100 ml. or under until the patient's discharge to duty.

One hundred of the 253 patients in the first study and 88 of the 189 in the second were selected at random for follow-up examinations from 4 to 18 months after return to duty (averages 12 and 8 months respectively). Information consisting of data gathered from a careful medical history and physical examination, usually by one of us, and from the performance of liver function tests, including that for sulfobromophthalein retention, was obtained on 176 of the 188 (94%), and incomplete data were obtained on an additional 7 patients (3%). One of us (C. W. S.) examined 29 former patients at Sasebo, Japan, while they were on their way back to the United States from Korea. One hundred forty were seen by three of us (J. G. C., N. D., and R. W. R.) after return to their homes or new assignments in the U. S. Specimens of serum from these and 10 others examined by cooperating doctors were sent to the research laboratory in Boston for analysis. Four of the patients were examined at the Army hepatitis center in Germany.

RESULTS

Two hundred fifty-three patients were included in the first study. Since there was no demonstrable interrelationship between the effects of rest and diet, for this report the patients on the two ad lib. rest wards were combined for comparison with those on the two strict bed rest wards. The results are summarized in the table. The duration of the acute illness, defined as the time from admission to findings of a total serum bilirubin level of 1.5 mg. per 100 ml. or less and a sulfobromophthalein retention of 5% or less in 45 minutes, was essentially the same for the two groups. The relation of duration of illness (treatment effect) to the height of the initial level of serum bilirubin is shown in figure 1. The findings in

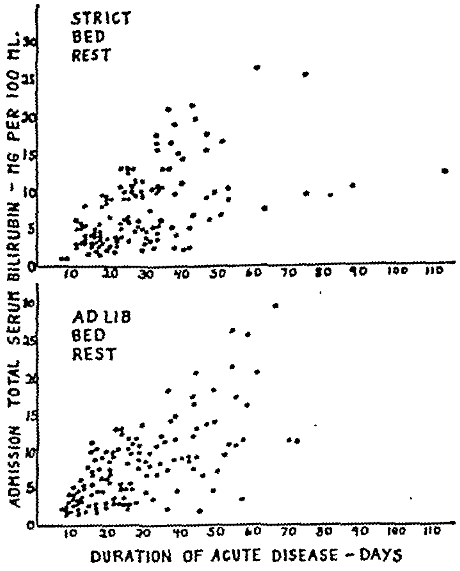

Fig. 1.—The relation of level of total serum bilirubin found on admission for treatment of acute infectious hepatitis to duration of acute illness in each treatment group.

[5] Chalmers, T. C., and others: The Treatment of Acute Infectious Hepatitis: Controlled Studies of Effects of Diet, Rest, and Physical Reconditioning on Acute Course of Disease and on Incidence of Relapses and Residual Abnormalities, J. Clin. Invest. 34: 1163, 1955.

the two groups were similar. There was no difference between the treatment groups in the rate of fall of the serum bilirubin level or in the rate of the disappearance of symptoms and signs of the disease. In particular, there was no evidence that ad lib. rest resulted in prolongation of hepatic tenderness or enlargement (fig. 2). Flocculation and thymol turbidity tests were the same in the two groups. During the convalescent period, an equal percentage of each group had a return of abnormal sulfobromophthalein retention lasting an average of 32 days and unaccompanied by symptoms or jaundice. In the follow-up study it was found that 5 of the 46 patients treated with strict bed rest and 3 of the 49 patients treated with ad lib. rest had been hospitalized for more than one day for symptoms and findings possibly related to their previous acute hepatitis. No case of recurrent jaundice was seen. The occurrence of symptoms after discharge to duty was equal in the two groups (fig. 3). An approximately equal number in each group on follow-up examination were found to have residual abnormalities in the realms of symptoms, signs, and liver function tests, most of which were considered to be minor in importance.

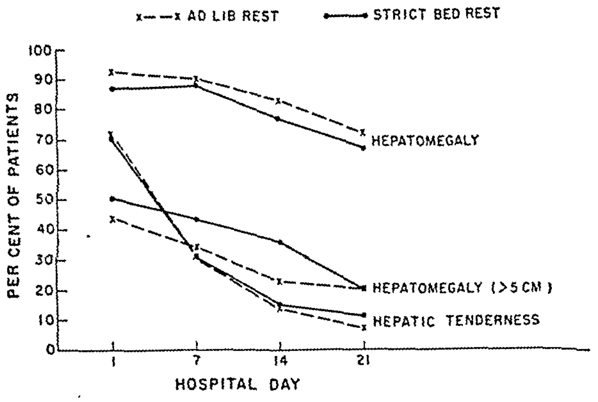

Fig. 2.—Frequency of liver enlargement and tenderness in first study of treatment of patients with acute infectious hepatitis.

In the second study, 95 patients subjected to early strenuous exertion at a physical reconditioning center revealed minor rises in level of total serum bilirubin and sulfobromophthalein following tests, as well as an increased occurrence of symptoms and nontender hepatomegaly during the first week of reconditioning when compared with the control group of 94 patients kept in the hospital. Although statistically significant, these changes were not considered to be of clinical significance because they were small, they disappeared in spite of continued exercise, they were seldom combined in the same patient, and they were not accompanied by unequivocal residual abnormalities in the follow-up study. Recurrent clinical jaundice was never seen after exercise. During the interval following discharge, only one of the patients included in the follow-up examination was hospitalized for a possible recurrence without jaundice. During the interval more of the patients with early reconditioning had vague right upper quadrant pains (fig. 3), and significantly more on follow-up examination had tender livers (see table). In view of lack of significant disability or other more objective abnormalities, clinical significance of these findings is unknown.

COMMENT

Thus, the previous belief that bed rest should be enforced after a patient feels well enough to be up and around his hospital ward has not been confirmed by the studies briefly summarized above. Likewise, no definitely deleterious effects of strenuous exercise early in convalescence have been demonstrated. Before recommendations can be made for a distinct change in the routine treatment of hepatitis, it is necessary to consider possible explanations for the discrepancies between data of previous and present studies. One or more of the following three factors may be operative: (1) inadequacies or misinterpretations of the present study, (2) a distinct change in the disease or clinical material, or (3) inadequacies or misinterpretations of past studies.

Except for the fact that it was impossible to rotate the patients among wards and to rotate the doctors among treatment groups, thus controlling unknown ward and doctor "effects," the studies reported above were well controlled. Analysis of 34 variables other than treatment that might have influenced the results revealed the groups of patients in the first study to be entirely similar. Thus, there was no evidence that the patients on the strict bed rest regimen were by chance more severely ill. On numerous daily "bed checks," no more than 10% of these patients were caught out of bed more than the allowed amount. In contrast, after the first few days of hospitalization none of the ad lib. rest patients spent all day in bed, and by the seventh day more than 50% of the patients were out of bed more than 50% of each day. Most of these patients were still jaundiced. Thus, the fact that the two groups of patients received distinctly different treatment was well documented. The number of patients was large enough to make it extremely unlikely that a real difference in favor of strict bed rest could by chance have been undetected. Finally, the follow-up study was adequate in terms of percentage of selected patients contacted.

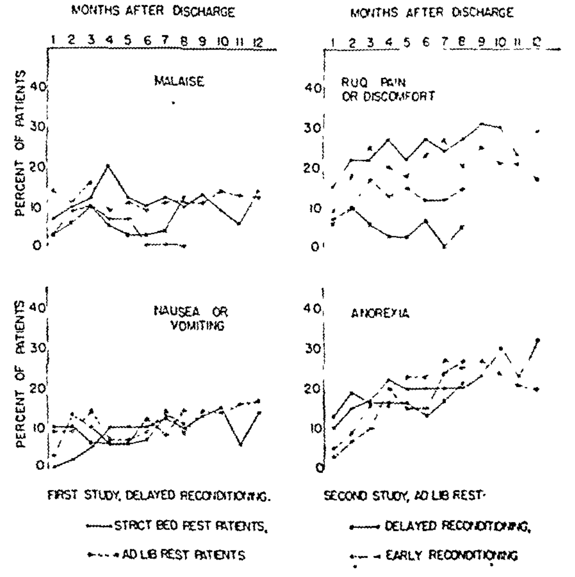

Fig. 3.—History, obtained at follow-up examinations, of symptoms during each month after patient's discharge from hospital. The rise in rates is probably the result of the better memory of the patients for recent complaints.

A comparison of the occurrence of symptoms, depth and duration of jaundice, and mortality reported in this epidemic and in previous epidemics of infectious hepatitis among military personnel [5] revealed no differences sufficient to explain the lack of effectiveness of bed rest in this epidemic. It is possible that more of the patients studied during World War II had homologous serum jaundice rather than infectious hepatitis, but this would seem to be an unlikely explanation of the enigma. The only striking difference lies in the incidence of relapses with jaundice. The 5% incidence encountered in patients studied in Italy during World War II [1a] may have been a manifestation of a more severe disease or may have represented reinfection accompanying the administration of plasma to the more severely ill patients. There is no doubt that the soldiers who were infected with hepatitis in Korea were less battle weary and better fed than those hospitalized in Italy at the height of the fighting in World War II. It is possible but has not been demonstrated [6] that depleted soldiers may have a more serious illness requiring more "conservative" treatment.

The most likely explanation for the discrepancies between our studies and past ones seems to lie in interpretations of the studies on which the conclusions about the essentiality of bed rest were based. In the three studies referred to above,[1] the effects of rest and diet were not differentiated, and the entire beneficial effect may have been due to diet. In addition, other factors that might have influenced the course were not strictly controlled, and the criteria for treatment effect were the durations of hospitalization rather than the more objective liver function test criteria employed in the present studies. Finally, fluctuations of clinical and laboratory tests occurring after ambulation, previously presented as data confirming the efficacy of bed rest, cannot be attributed to the ambulation without control data. In the study reported herein, minor fluctuations occurred at the time of ambulation of the patients on a regimen of bed rest with the same frequency as in the patients who had been up and around throughout the acute period of their disease.

The observation at the Army hepatitis center in postwar Germany that exercise had an adverse effect only in the patients whose serum bilirubin levels were above 3 mg. per 100 ml.[3] confirms the World War II experience that the forced exercising of jaundiced patients was accompanied by a high relapse rate. In the present studies no jaundiced patients were forced to exercise. The changes associated with early reconditioning in the second study and the persistence of hepatic tenderness in those patients suggest that there may be an association between strenuous exertion early in convalescence and liver function, but the clinical importance of this association seems minimal.

It should be emphasized that in these studies the ad lib. rest regimen was not started until an average of 10 days after the onset of symptoms. The patients were never forced to stay out of bed or to perform any ward duties and were confined to their hospital wards. The study offers no evidence, therefore, that rest is not advantageous in the earliest stages of the disease or when the patient feels sick. Unless these points are kept in mind, there will be some unfortunate misinterpretation of the conclusion that strict bed rest need not be enforced after the patient feels well.

The advantages of a regimen of ad lib. rest are obvious. Enforced bed rest may in itself be a debilitating disease with a discouragingly prolonged and symptomatic convalescence. It may be complicated, at least among older patients, by serious vascular accidents, renal lithiasis, osteoporosis, bed sores, or infection. From the military standpoint, the elimination of enforced bed rest and the resultant earlier return to full activity, demonstrated by the present studies to be safe procedures, will result in substantial savings in manpower and the expense of hospitalization.

SUMMARY AND CONCLUSIONS

A carefully controlled study of the effects of strict bed rest in the treatment of acute infectious hepatitis has failed to confirm its advantages after the earliest stages of the disease. It was found that patients treated with ad lib. rest could be started on physical reconditioning programs much earlier because they were not afflicted with the debilitating effects of prolonged rest in bed and did not require a convalescent period of gradually increasing ambulation.

On the basis of the experiences summarized above the following principles of treatment are suggested: 1. A patient with acute infectious hepatitis should be confined to his hospital ward or home and encouraged to stay in bed if he feels sick, but he need not be confined to bed if he feels like getting up, except for an hour's rest after each meal. 2. The level of serum bilirubin concentration should be checked at convenient intervals until it drops below 1.5 mg. per 100 ml. If the sulfobromophthalein retention determined at this time is 5% or less in 45 minutes, the patient may begin to resume normal activity but should have the bilirubin level determined and sulfobromophthalein test repeated after two to four weeks. 3. If the sulfobromophthalein retention stabilizes at between 5 and 10%, the patient may be discharged with safety. Those patients with persistently higher levels of retention or with fluctuating total serum bilirubin levels will require individual management. Liver biopsy may be indicated in the evaluation of these patients. 4. Recurrent abnormalities of the liver function tests will occasionally occur after return to normal activity and may be sufficient reason for reconfinement of the patient.

Chloramphenicol.—The discovery of chloramphenicol (Chloromycetin) by Burkholder in 1947 established the fact that an antibiotic effective against a wide variety of microorganisms could be produced by microorganisms isolated from natural sources. Such substances are now known as "broad spectrum" antibiotics. Chloramphenicol was originally obtained from a soil sample collected in a field in Venezuela and from a similar organism isolated from a compost soil in Illinois. The original microorganism was named Streptomyces venezuelae. However, other strains of actinomycete also produce the antibiotic.—P. P. Regna, Ph.D., Chemistry of Antibiotics of Clinical Importance, *The American Journal of Medicine*, May, 1955.

EDUCATIONAL NEEDS—ANESTHESIOLOGIST'S RESPONSE

Ralph S. Sappenfield, M.D., Miami, Fla.

The development of the field of anesthesiology in the past two decades is built upon the cornerstone hewn by such men as Waters, Lundy, Guedel, Bourne, Griffith, and Leigh. This growth gained a new impetus after World War II that added strength, an expansion of services, and a promise in the field of anesthesia to fulfill the ideals of organized medicine and to meet the demands of a new concept in patient care. Basic knowledge in this field has expanded to cover a wider range of subjects and skills from an era when it consisted almost exclusively of the technical ability to render a patient insensitive to pain. Now, the versatility of the present-day anesthesiologist is utilized in many ways other than administering anesthetics. Today, through his knowledge of the basic sciences, the anesthesiologist is also a clinical physiologist and pharmacologist.[1]

When we think of the long period involved in the laying of this foundation of present-day anesthesia, our thoughts drift from that Spanish physician who discovered a drug now known as ether to Crawford Long and William Morton. Progress remained very slow for a long time, probably because of the many problems that existed in the over-all picture of medicine. Now many have entered this field having recognized the importance and quality of the intellectual challenge and are building a structure of improved care with greater safety to our patients.

ADVANCEMENT OF EDUCATION AND RESEARCH FACILITIES

During this early period of medical development with its complex problems, the American Medical Association was conceived and founded upon certain basic principles—one of which was the advancement of education and research facilities. The need to encourage, nurture, and stimulate those ideals in well-founded institutions was only a part of the program; the need to point out and to abolish the diploma mill was also most flagrant. The results of this effort are gratifying—undergraduate and graduate medical education have been elevated to a plane that is mandatory of a progressive attitude. The report of a two and one-half year survey of postgraduate medical education by the Council on Medical Education and Hospitals was published in THE JOURNAL.[2] This report is not only quite complete and informative but most pleasing regarding educational facilities and accomplishments in the United States today.

The American hospital administrators, because of their feeling of a moral and legal responsibility for the quality of medical care in their hospitals, are concerned that the practice of medicine be carried out properly, and they realize that this responsibility requires understanding, education, and proper organization. They also feel that many problems must be considered from the viewpoint of the medical profession for good patient care. The American Medical Association and the various American boards have set up standards that assure us of adequate postgraduate training programs. At the present time there are 185 residency training programs in anesthesiology with 746 residents in the United States receiving training under these standards.[3] The growth of this program has been great. With this growth in research and knowledge, and a better understanding of preoperative and postoperative care, many operations can now be performed that before would have been considered impossible or too serious a surgical risk. Modern anesthesia has removed this limiting factor in the surgeon's work. Research and knowledge in anesthesia have been developed more rapidly than their application could be transferred to the patient in the operating room. A quality of anesthesia care equal to the quality of surgical care is lacking in too many localities. This critical shortage of adequate anesthesia care has been discussed at conferences of hospital administrators throughout the country. These individuals fully realize the trend for the general practitioner to locate near large medical centers that have already attracted our trained men in a limited field of practice. The hospital associations are requesting assistance in solving this problem of adequate anesthesia coverage for the smaller institutions. They have also suggested a liaison committee with the American Society of Anesthesiologists and the American Hospital Association in order to clarify the relationship of the specialty with the hospital administration, which we of this group must encourage.

In reviewing the recent survey of the American Society of Anesthesiologists it is noted that the part-time anesthesiologist, who is the general practitioner, is administering a large percentage of anesthesia throughout the United States. This is particularly true in the rural and sparsely populated areas that have benefited under the Hill-Burton act. In many instances he is placed in this position by necessity rather than desire and because of this has requested educational assistance. This physician with a small amount of academic instruction is a safer administrator of anesthetics than is the technician

who may be a perfectionist in the clinical procedure but who is lost under an uninformed doctor's authority when the unusual occurs.

The need for better patient care as voiced by the hospital administrators and the earnest desire for more knowledge by the general practitioner have been heard by organized medicine and the American Society of Anesthesiologists. The responsibility and obligation to offer training programs for part-time anesthesiologists in order to improve the anesthesia available to the public has been cheerfully accepted by the trained anesthesiologist. Several flexible programs have been made available to all desiring them in all parts of the country. The refresher courses with a variety of subjects and a number of instructors have been sponsored by many local hospitals and county, regional, and state organizations. One of the largest programs is that sponsored by the Committee on Medical Schools and Postgraduate Education of the American Society of Anesthesiologists. This refresher course program has been enthusiastically received by those attending, which is shown by its rapid and steady growth. It is but one of several programs offered as regional-sponsored courses, which cover from 3 to 14 days. Primarily these are intended to attract physicians practicing anesthesiology full time, those in residency training, and those interested in research. Because of these factors and the travel time necessary, this portion of the educational program does not appeal to the part-time physician anesthesiologist.

CURRENT ANESTHESIOLOGY PROGRAMS

Postgraduate courses in the various phases of anesthesiology, such as inhalation anesthesia, regional anesthesia, and replacement therapy, have been offered for several years. These are concentrated courses in which the individual sessions follow one another, day after day, in such a way that the physician attends the course from the beginning to the end as a full-time student. This type does not require the physician to leave his practice for a long period of time, and in many instances it is possible to attend during a vacation period. Usually the entrance fee is minimal. An objection that has been offered to this type of training is the limited number of instructors involved in each course. Vollan in his report describes this part-time specialist, one who does general practice with particular attention to a specialty, as probably the largest consumer of special postgraduate courses limited to a narrow field of medicine, and it appears to him that increased training stimulates a desire for further postgraduate work rather than reducing it.[2b]

In order to satisfy further the educational needs of the physician who wishes to do a better job for his patient, a more flexible program has been made available. During the early part of 1955, a committee under the direction of Dr. Oral B. Crawford requested each state society of anesthesiology to form a committee to assist in the development of this phase of postgraduate education for the part-time anesthesiologist.[4] As soon as this was accomplished and each committee was instructed in the responsibility for the organization and presentation of this program, questionnaires were sent to the secretary of each county medical society and to each hospital administrator. From these returned questionnaires, the names and addresses of approximately 5,000 part-time anesthesiologists have been obtained. Not one of these is of a nationally organized group. Each of these part-time anesthesiologists was sent a questionnaire to ascertain his interest in obtaining postgraduate training in anesthesia. If he is interested in such a program, a further attempt will be made to determine the techniques that he employs, the type of training that would interest him, the time he will have available, and the drugs and techniques in which he desires more knowledge and skill. From questionnaires sent to teaching institutions and chairmen of departments of anesthesiology, a list of locations of postgraduate courses available to general practitioners has been compiled. To this list of almost 100 available locations, a brief description of the course was added, including the type of training, duration of the course, time it is offered each year, fee, and for whom it is designed. This list has been made available not only to these 5,000 physicians but to all general practitioners who attended their annual meeting in Los Angeles, March, 1955, and it will also be published.

In the development of this phase of training many of the objections previously found are avoided. The number of institutions willing to participate is increasing and can be found in practically every area of the United States. Anesthesiologists are anxious to make the clinical and didactic material available to student physicians at times convenient for them to leave their patients and to assist them in meeting the postgraduate training qualifications set up by the American Academy of General Practice, which requires its members to show evidence of 50 hours of formal training every three years in order to retain membership in the organization. The College of General Practice of Canada has recently been organized, and it requires 50 hours of formal graduate work every two years. The trained anesthesiologist wishes to do his part for both of these organizations to keep their membership up-to-date at all times and with as small a financial outlay as possible. Many institutions are cooperating without any tuition unless it is necessary for administrative reasons.

In the formation of these individualized programs, the special needs of each physician will be determined by close supervision of this clinical work. He will learn by doing, which places the burden upon the student. During this association the fundamental techniques and concepts will be instilled in him to think as an anesthesiologist and to find his place as a consultant in this physician-patient relationship. Anesthesiology has been made deceptively easy and, therefore, potentially dangerous in the hands of the inexperienced. The general practitioner in regular hospital work can and must do better than perpetuate outmoded methods of the past.[5]

USE OF PHENACEMIDE IN EPILEPSY, WITH ANALYSIS OF FATAL REACTIONS AND CASE REPORT

Wallis L. Craddock, M.D., Fort Douglas, Utah

Phenaçemide (Phenurone) is of proved value in psychomotor epilepsy. It is capable of relieving patients resistant to other antiepileptics, although its therapeutic effectiveness must be balanced against its toxic effects. Phenobarbital and diphenylhydantoin (Dilantin) are relatively safe drugs in the treatment of epilepsy; however, other anticonvulsant drugs, such as 3-methyl-5,5-phenylethylhydantoin (Mesantoin), trimethadione (Tridione), paramethadione (Paradione), and phenacemide, may produce moderately severe, but reversible, side-reactions and, in some patients, dangerous effects. Newer anticonvulsants such as primidone (Mysoline), metharbital (Gemonil) and N-methyl-α-phenylsuccinimide (Milontin) require further clinical study before their value in relation to other antiepileptics can be assessed. Milontin, for example, has been shown to cause transient renal damage. The problem of various hypersensitivity reactions as related to these drugs is now being brought into sharp focus because of such reactions.

Phenacemide is the only one of these drugs known to have caused fatal toxic hepatitis. Death from acute hepatitis due to Mesantoin had been reported in one patient, but subsequent investigation apparently absolved from blame the use of this drug as the cause of death. It is the purpose of this papér to analyze the eight reports of deaths associated with phenacemide therapy, to present one of these case reports, and to discuss briefly the pharmacology of, indications for, and precautions in the use of the agent, with the hope that the clinician may become more aware of untoward reactions from this agent and associated agents.

PHARMACOLOGY

Chemically phenacemide is phenacetylcarbamide or phenacetylurea. It is closely related in structure to diphenylhydantoin and to Mesantoin; if the hydantoin nucleus is opened between the carbon 5 and the adjacent nitrogen, a straight-chain compound, the corresponding acetylurea, is formed (fig. 1). Phenacemide contains the phenyl radical that seems to be one of the important substituents in the anticonvulsant activity of both the barbituric acid derivatives (phenobarbital and mephobarbital) and the hydantoin derivatives (diphenylhydantoin and Mesantoin). It is noteworthy that the phenyl radical is not present in the oxazolidine derivatives (trimethadione and paramethadione), drugs particularly effective in petit mal epilepsy.

Phenacemide was synthesized by Spielman and coworkers in 1948, examined for anticonvulsant activity by Everett and Swinyard, and first reported clinically by Gibbs and associates in 1949, who found it particularly effective in patients with psychomotor seizures. Subsequently, a large number of publications called attention not only to the unique value of phenacemide in psychomotor epilepsy but also to the considerable hazard involved in its use. An extensive review of data is that of Tyler and King, who analyzed the major side-effects. Phenacemide has a very low toxicity when given to experimental animals, and it effectively raises the threshold for, or completely suppresses, both electroshock and pentylenetetrazol (Metrazol) convulsions. Experimental evidence indicates that the liver plays a part in the destruction of phenacemide. Dogs given large doses for 18 months appeared to be healthy and had normal values for blood and urine analyses and kidney function tests. Liver function tests remained normal, or showed only slight impairment in some tests. Repeated bone marrow smears from the dogs showed normal marrow elements. It is claimed that in animals large areas of liver must be damaged or resected before any damaging effects from use of the drug are noted. In comparative tests phenacemide has been considered equal or superior to available anticonvulsants and has been found superior to all other drugs tested against psychomotor-type seizures produced in animals.

INDICATIONS AND PRECAUTIONS FOR USE

Because of the possibility of severe hypersensitivity reactions (to be outlined later) phenacemide should be administered only after other accepted anticonvulsants have been tried and found ineffective in controlling the seizures. Since phenobarbital and diphenylhydantoin are relatively safe and effective anticonvulsants, these drugs should be given an adequate trial in the majority of new cases. When it becomes necessary to use drugs such as Mesantoin, trimethadione, and phenacemide, the initial dose should be small. A carefully taken history of allergy, skin reactions, bleeding tendencies, and irregularities of the gastrointestinal tract and renal systems must be obtained. The intelligence, cooperation, geographical accessibility, and reliability of the patient should be determined. The patient should be informed of the risks and symptoms of side-effects and of the urgency of immediate reports to the physician when symptoms do occur. Before treatment is started, a urinalysis, blood cell count, platelet estimation, and hematocrit determination should be made. In addition, a urobilinogen test is necessary when phenacemide is to be used. These examinations should be repeated at two week intervals during the first year and once a month thereafter. Such precautions will prevent most fatal reactions. If the cost and inconvenience of these procedures make them impractical, the drugs should not be used. Sudden withdrawal of effective medication, especially diphenylhydantoin or phenobarbital, is dangerous because a plethora of seizures may follow. Use of these drugs do not cause mental

This paper has been reviewed by the Veterans Administration and is published with the approval of the Chief Medical Director. The statements and conclusions of the author are the result of his own study and do not necessarily reflect the opinion or policy of the Veterans Administration.

deterioration if prescribed in suitable doses, but, with certain ones, a constant vigil must be maintained for evidence of toxicity. Occasionally, severe mental aberrations make it advisable to stop use of the drugs. Toxic reactions may occur very early or very late. Unremitting caution must be exercised in using anticonvulsants, and a record must be kept of persons receiving them. A note should be made of the date the patient is scheduled to have follow-up laboratory examinations. If the appointment is not kept, a registered letter should be sent repeating the warnings already given the patient and urging prompt attention. Including the following case, there have been eight deaths recorded that have been attributed to the use of phenacemide. These cases will be analyzed later.

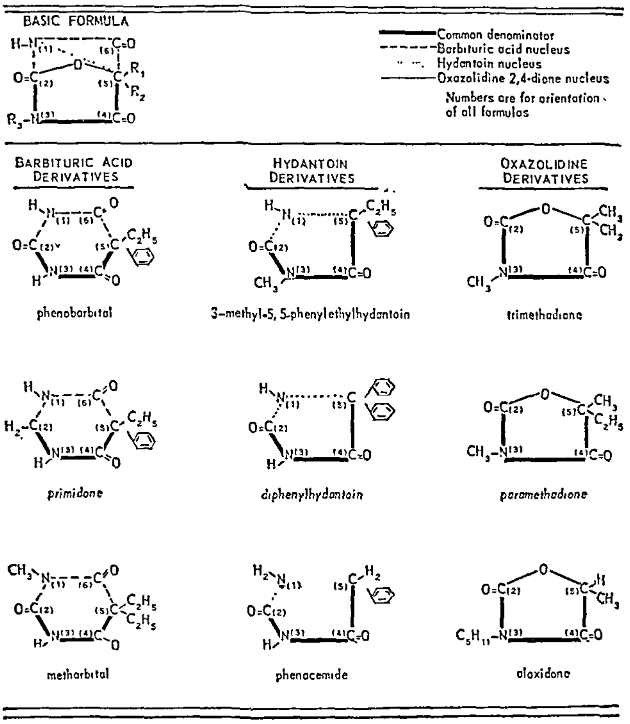

Fig. 1.—Chemical structure of commonly used anticonvulsant drugs (after Goodman, L. S., and Gilman, A.: The Pharmacological Basis of Therapeutics, ed. 2, New York, the Macmillan Company, 1955, pp. 180-182).

REPORT OF A CASE

A 35-year-old male veteran was admitted to the Veterans Administration Hospital, Fort Douglas, Utah, on Aug. 20, 1953, for treatment of epilepsy. He had been taking diphenylhydantoin and phenobarbital since 1946, when a diagnosis of grand mal epilepsy was first made. He exhibited mental deterioration, and his seizures had become resistant to the common forms of anticonvulsant medication, including trimethadione. His physical condition had always been good. There was no history of jaundice, cirrhosis of the liver, or disease of the hematopoietic system, nor was there any history of dermatitis or illness compatible with a drug hypersensitivity reaction.

Although he always enjoyed excellent physical health and had no interim infections, he continued to have grand mal and psychomotor seizures. He was increasingly aware of memory loss, and at the time of his admission to our hospital his behavior was described as psychotic. He had been taking 0.1 gm. of diphenylhydantoin and 0.032 gm. of phenobarbital three times daily. No other medication had been given for a period of six months prior to hospitalization, and he only received anticonvulsant drugs during his hospitalization. Trimethadione had been given several times in the past without evidence of toxicity; its use was begun again Sept. 18, 1953, 0.3 gm. twice daily.

Phenacemide was first given on Dec. 5, 1953, 0.5 gm. twice daily. His convulsive episodes became fewer, but his behavior remained schizoid. Under guardianship, he was granted a leave of absence from Dec. 22, 1953, to Jan. 4, 1954. There were no changes in liver function tests, including urine urobilinogen, and blood cell counts and urinalyses stayed normal.

He returned from leave in good condition. No changes in his behavior were noted until Jan. 12, 1954, when he appeared ataxic and more confused after a grand mal seizure. He became noticeably jaundiced on Jan. 16, 1954, and therapy with all anticonvulsant drugs was discontinued. He had received therapy with these drugs in the following quantities: diphenylhydantoin, 0.3 gm. daily for nearly eight years; phenacemide, 42 gm. (total dosage) over a period of 42 days; and trimethadione, 72 gm. (total dosage) over a period of 109 days. He became rapidly comatose, the icteric index rose to 100 units, and the serum bilirubin level rose to 25 mg. per 100 cc. on Jan. 18, 1954. Blood glucose, blood urea nitrogen, and carbon dioxide combining power of the blood were normal on that date, as were the serum cholinesterase, serum cholesterol, and serum alkaline phosphatase determinations. Prothrombin activity was recorded as less than 10% of normal. The cephalin flocculation test was 3+; the thymol turbidity test was normal. A qualitative urine urobilinogen test was strongly positive. Plasma electrolytes, including sodium, potassium, and chlorides, were normal. Bleeding time, coagulation time, clot retraction, and number of platelets were normal. Urinalysis was negative. The hematocrit determination was normal. Leukocyte count was 12,000 per cubic millimeter, with no other abnormal findings on the smear. A spinal fluid examination was negative; fluid dynamics were normal. The chest roentgenogram (portable) revealed no abnormal findings. The electrocardiogram showed no unusual features except sinus tachycardia. The patient did not respond to therapy. By Jan. 19, 1954, he was in deep hepatic coma and fetor hepaticus was easily detected. Despite vigorous supportive measures, he died on Jan. 20, 1954, without further convulsive seizures and without showing hemorrhagic tendencies.

Autopsy Findings.—Postmortem examination revealed generalized discoloration of tissues due to hyperbilirubinemia and changes in the liver characteristic of acute yellow atrophy. The liver was greatly diminished in size, weighing only 800 gm. The capsule was smooth and glistening, and in some areas the lobular pattern of the liver could be identified through the capsule. The parenchyma was moderately flabby and, when laid on the table, caused the liver to assume a pancake-like shape. On sectioning, the parenchyma bulged beyond the capsule, and it was mottled with red pinpoint areas and streaks of yellow. The hepatic lobules were scarcely visible. Microscopically, the picture was one of profound disintegration and necrosis, the structure of the hepatic cells being completely lost and replaced by granular debris (fig. 2). Only a thin rim of intact hepatic cord cells surrounded the periportal triads. The biliary radicles and vessels did not appear

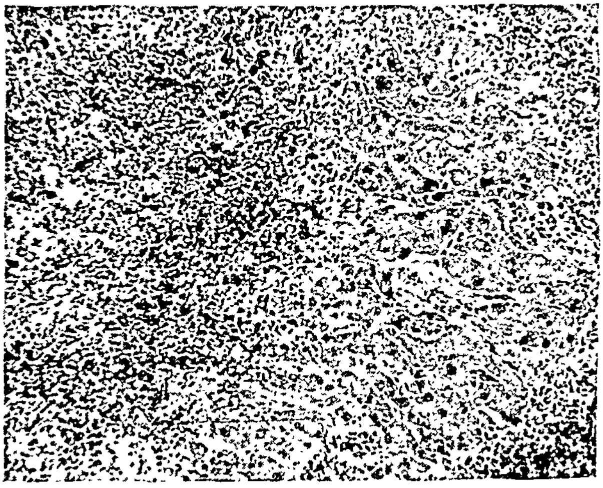

Fig. 2.—Photomicrograph showing profound disintegration and necrosis of liver cells in acute yellow atrophy (× 100).

abnormal. There were no changes of note involving the kidney, heart and vessels, pancreas, brain and spinal cord, gastrointestinal tract, lungs, lymph nodes, bone marrow, adrenal glands, spleen, or other organs.

DEATHS ASSOCIATED WITH PHENACEMIDE THERAPY

Levy and others[1] have suggested the following criteria to establish the basic role of drug toxicity in any given case: 1. The patient must have been in good health prior to the administration of the agent. 2. The causative agent must have been given over a sufficient period, uncomplicated by other medicaments. 3. The illness in question must be unrelated to any other obvious etiological process. 4. The drug must be shown to have caused similar toxic effects in animals or in human subjects. 5. Pathological findings must confirm the involvement of the systems affected in the clinical picture. All these criteria are fulfilled in the eight fatalities attributed to phenacemide therapy (see table), with minor exceptions that will be discussed. It is difficult to exclude the possibility of viral hepatitis, but in each case the relation of the phenacemide treatment and the hepatitis can be regarded as more than coincidental. Analysis of these deaths in association with a new drug is of the utmost importance; the dangerous toxic effects of trimethadione, paramethadione, Mesantoin, and phenacemide have been reviewed elsewhere. Drug-induced hypoplastic anemias are common to all of them, but Mesantoin offers the highest risk in this connection. Several cases of the nephrotic syndrome resulting from trimethadione have been reported. At least 40 fatalities from the use of these drugs have now been reported during the past seven years. Osgood[2] concludes that phenacemide is an agent known to produce hypoplastic syndromes of the drug hypersensitivity reaction type. The mechanism *of action is still uncertain. The two cases of aplastic* anemia attributed to phenacemide have been described in detail by Forster and Frankel[3] and by Simpson and others.[4] In these cases it appears that phenacemide was the anticonvulsant causing the deaths. Mesantoin therapy had been used in both patients but had been discontinued 60 and 175 days, respectively, prior to onset of toxic reactions in these two cases (see table, cases 1 and 2).

Analysis of Deaths Attributed to Phenacemide Therapy

			Therapy			
			Phenacemide			
Case No.	Observer	Year Reported	Days	Total Dose, Gm.	Other Anticonvulsants	Pathological Findings
1	Forster and Frankel[3]	1949	60	90	Diphenylhydantoin, 14 mo.; Mesantoin, 6 mo. (therapy discontinued 60 days before death)	Aplastic anemia
2	Simpson and others[4]	1950	180	425	Diphenylhydantoin, 2 yr.; Mesantoin therapy discontinued 175 days before symptoms	Aplastic anemia
3	Levy and others[1]	1950	80	120	Diphenylhydantoin, 9 yr.	Hepatorenal syndrome
4	Levy and others[1]	1950	44	51	Mesantoin and trimethadione, 9 mo.; diphenylhydantoin for years	Acute yellow atrophy of liver, with significant renal findings
5	Davidson and Lennox[8]	1950	45	50	Diphenylhydantoin, many years	Acute, severe parenchymal liver damage, superimposed on older portal cirrhosis, mild
6	Liversedge and others[9]	1952	25 †	72	Trimethadione therapy discontinued 12 mo. prior because of rash and leukopenia	Acute yellow atrophy of liver
7	Field and Just[10]	1954	210	669	Diphenylhydantoin, 21 mo. (total dose, 252 gm.)	Massive necrosis of liver parenchyma
8	Craddock *	1955	42	42	Trimethadione, 110 days (total dose 72 gm.); diphenylhydantoin, 7 yr.	Acute yellow atrophy of liver

* This report.

† Rash appeared after 23 days, and therapy was restarted two weeks later for 2 days.

It is significant that of the more widely used anticonvulsant drugs, phenacemide is the only one proved to have caused severe toxic effects on the normal liver. Therefore, the clinician must constantly look for evidence of impending liver damage while his patient is undergoing therapy with the drug. Before any deaths were reported from toxic hepatitis, Lloyd-Smith[5] described a case of acute hepatitis, with jaundice developing after 70 gm. of phenacemide had been given for two months. The serum bilirubin level was 4.4 mg. per 100 cc.; the alkaline phosphatase level was 13 units per 100 cc. (Bodansky); the cephalin flocculation was 4+; and the thymol turbidity was reported as 7 units. One week after cessation of therapy with the drug, the jaundice disappeared and liver function tests had returned to normal. Livingston and Kajdi[6] alluded to the occurrence of nonfatal hepatitis in one out of 104 patients receiving the drug, and Carter and others[7] described two cases of acute hepatitis with recovery among 63 patients taking phenacemide. These cases proved to be an indication of the ability of this agent to produce more serious toxic effects on the liver, and within a few months the first three cases of fatalities due to phenacemide-induced hepatitis were reported. In one of these patients there were also changes representing the resolving phase of lower nephron nephrosis[1] (see table, case 3). The icteric index had risen to 42 units; albuminuria was present, and the blood urea nitrogen level was 227 mg. per 100 cc. The prothrombin

activity was 40% of normal, and the cephalin flocculation was 3+. The patient remained comatose for one week and became anuric. The autopsy revealed a liver of normal size and grossly normal appearance; however, microscopic examination revealed injured hepatic cells displaying various degrees of change, consisting essentially of a granular cytoplasm with numerous, indistinct vacuoles. The parenchyma of the kidneys appeared somewhat swollen and edematous. Microscopically, the glomeruli appeared normal, but many of the distal convoluted tubules were dilated and some were filled with pink-staining casts.

Levy and others[1] reviewed the clinical course and autopsy findings in another patient (see table, case 4) who died of acute yellow atrophy of the liver. This patient was receiving Mesantoin, trimethadione, and diphenylhydantoin. He died in coma 51 days after phenacemide was included in his therapy; he had been given therapy with Mesantoin and trimethadione for nine months and had received diphenylhydantoin for many years. The liver appeared shrunken and was soft and friable. Microscopic examination of the liver revealed extensive destruction of the basic lobular architecture and severe necrosis of most of the hepatic cord cells. In addition, gross inspection of the kidneys showed them to be swollen, but the capsule stripped with ease. Microscopic examination revealed ischemic glomeruli, with thickening of the capillary walls, and there was marked degeneration of both straight and convoluted tubules.

Davidson and Lennox[8] described a case of severe acute parenchymal damage of the liver (see table, case 5). Therapy with diphenylhydantoin had failed to give any relief from the seizures; no other medication was given. Phenacemide was administered for only 45 days (total dose 50 gm.), but after three weeks with phenacemide therapy the patient complained of lethargy, diarrhea, and anorexia. Symptoms were first attributed to an epidemic gastrointestinal disturbance then prevalent in the community. Jaundice was noted three weeks later; the patient died shortly thereafter from hepatic coma. Autopsy revealed acute, severe parenchymal damage to the liver, superimposed on an older portal cirrhosis of mild to moderate degree. A case of acute yellow atrophy of the liver following phenacemide therapy was next reported by Liversedge and others.[9] It is very significant to note that the patient developed a severe skin rash when trimethadione was given a year previously; there had been no other sign of toxic effect from trimethadione, but therapy with the drug was discontinued. Therapy with phenacemide was likewise discontinued when a rash developed after 23 days of treatment; it was restarted two weeks later on the insistence of the mother of the patient, since seizures had again become severe. Two days after the readministration of phenacemide therapy, the child became very listless and his eyes were noticeably puffy. Therapy with the drug was again stopped, but jaundice and hepatic coma ensued and the patient died. The most striking laboratory finding was the extremely low level of prothrombin activity; the authors urge that prothrombin activity be followed when patients are treated with phenacemide therapy. Autopsy in this case revealed liver lesions characteristic of acute yellow atrophy; the kidneys were normal. Field and Justi[10] have reported another case of fatal hepatitis after phenacemide therapy for epilepsy (see table, case 7). The interval between the initiation of phenacemide treatment and death in this case was seven months—much longer than that of the other cases (25 to 86 days). Postmortem findings included evidence of massive destruction of the liver parenchyma, and the only viable tissue was a collection of hepatic cell cords.

I have had the opportunity to study the case of a 42-year-old woman admitted to the Letterman Army Hospital, San Francisco, on April 20, 1954.[11] She had received phenacemide therapy for approximately 200 days; the total dose of the drug was about 100 gm. She was critically ill and had recurring chills, jaundice, and a temperature of 104 F (40 C). She was also mentally confused. The liver was moderately enlarged, and there was marked ascites. Pertinent laboratory findings were as follows: serum bilirubin level was 4.2 mg. per 100 cc.; sulfobromophthalein retention was 30% in 15 minutes; blood urea nitrogen level was 18 mg. per 100 cc.; and serum protein levels were normal. Repeated paracenteses were performed weekly, and as much as 8,000 cc. of straw-colored fluid with the characteristics of a transudate were removed on one occasion. Biopsy of the liver revealed "focal necrosis and fibrosis with slight periportal inflammation." Because of impending hepatic coma, 400 mg. of cortisone was given daily, and a profuse diuresis occurred after two weeks of hormonal therapy; the ascites disappeared completely. Therapy with cortisone was discontinued after three weeks, during which a total of 8.5 gm. had been given. A second biopsy of the liver on June 11, 1954, revealed "focal postnecrotic scarring, with a definite increase in fibrous tissue, as compared to the previous liver biopsy; there is evidence of regeneration of bile ducts and liver cells." The patient has been maintained on therapy with diphenylhydantoin and phenobarbital since discharge from the hospital on June 16, 1954, and she remains well. This case, as well as other cases recently reported in the literature, illustrates the value of cortisone therapy in patients with impending hepatic coma.

COMMENT

Since hepatic coma appeared to be the terminal feature in six of the deaths attributed to phenacemide therapy, it is appropriate to review certain clinical features of this event. This type of coma is first characterized by lethargy or abnormal excitement progressing to unconsciousness, often attended by convulsions, in the immediate period before death. The appearance of the disordered mental state, the convulsive episodes, and the coma coincide with what appears to be serious metabolic decompensation. Fever, fetor hepaticus, Kussmaul-type respiration, dryness of mucous membranes, muscular twitchings, oliguria, and anuria are some of the findings suggestive of gross physiological breakdown; however, review of the findings obtained from routine blood and

hepatic tests serves to emphasize their lack of sensitivity for predicting or measuring hepatic damage.

The basic pathology of this condition is varied, as has been shown by the different microscopic findings in the 11 cases reviewed by Carfagno and others.[12] The maintenance of a normal concentration of blood sugar and blood urea nitrogen in most of these cases does not detract from the significance of reduced levels in the individual patient with advanced parenchymal failure. The point can be made, however, that the metabolic derangements in hepatic coma do not necessarily depend on or coincide with depression of these levels. The appearance of jaundice marks the stage of serious parenchymal failure. The positive cephalin flocculation test in most cases contrasts with the normal thymol turbidity and the alkaline phosphatase tests. The blood electrolyte studies reveal little indication of the severity of hepatic parenchymal failure. Other abnormalities that may appear include elevated or increased blood levels of ammonia, ketones, and pyruvate; decreased levels of cholesterol and cholesterol esters; and failure of various enzyme systems. The electroencephalogram may show definite slowing of the brain waves and a decrease in their amplitude. Neutral fat and fatty acid levels are not consistently changed.

SUMMARY AND CONCLUSIONS

It is significant that, of the commonly used anticonvulsant drugs, phenacemide (Phenurone) is the only one proved to cause severe toxic effects on the normal human liver. One of the most striking findings in the cases discussed in this paper appears to be the very low level of plasma prothrombin activity, often associated with relatively normal values for other tests of liver function. Hepatic coma appeared as the terminal mechanism in six of these cases. All the newer anticonvulsant drugs have produced dangerous, often fatal, reactions. Evidence has been presented that periodic blood cell counts and liver function studies may be of little aid in reducing the morbidity or mortality caused by therapy with these drugs. It is considered that the therapy of first choice in grand mal epilepsy is diphenylhydantoin (Dilantin) alone, or with phenobarbital, for a reasonable period of time (three to six months). Therapy with the other drugs should be given only after careful consideration, with the knowledge that occasional fatalities may be anticipated. The question as to whether the toxicity of a drug outweighs its therapeutic advantages must be answered before employing it. A drug obviously should be used with caution in any individual with a history of previous liver or renal disease. It is best to limit the use of phenacemide therapy to patients with psychomotor epilepsy. Better and safer agents for treatment of grand mal epilepsy are available. In psychomotor epilepsy, either diphenylhydantoin or primidone (Mysoline) are drugs of first choice; phenobarbital is of little or no value. If the psychomotor seizures are uncontrolled, it is best to try 3-methyl-5,5-phenylethylhydantoin (Mesantoin) before a final resort to phenacemide therapy.

THE PHYSICIAN AND THE CHAMBER OF COMMERCE

Edgar L. Dessen, M.D., Hazleton, Pa.

American physicians, theoretically in the forefront as proponents of the free enterprise system, are actually denying their support to that system. Too many of them are withholding physical and financial support from their local chambers of commerce, potentially the strongest single force in existence to perpetuate and refine our free enterprise system and to improve the general welfare of our communities. Strong words? Yes, but true. Although some few communities in this country have as high as 90% of their physicians belonging to the local chamber of commerce, others have as low as 10%, and the general average for the entire nation is undoubtedly considerably below 50%.

The situation is a great professional paradox. The physicians have by far the highest average educational level in any community—they have had at least eight years of education beyond high school and some even more. They are above the average in intelligence, or they would not have survived the high selectivity of the physician's training program. They are well above the average income level, if only for the statistical reason that people with higher educations have 77% of the country's $5,000 a year incomes and 82% of the incomes that exceed $10,000. And finally, they are accorded a prestige unique in American life, a prestige that is inescapable, immeasurable, and occasionally incomprehensible. These educational and financial and general social advantages set physicians apart as a great potential influence in chamber of commerce work. It is an influence that is sorely needed and wanted. If this privileged class does not assume the responsibilities of American ideology and of community welfare, who in the community should?

RESPONSIBILITY AS CITIZENS

The very prestige of the physician has undoubtedly in the past acted as a deterrent to his participation in chamber of commerce work. He has often practiced his divine healing art on a pink cloud, far off by himself, uninterrupted and unaffected by the microcosmic and the mundane. In recent years he, along with other professional people, has fallen out of his cloud with a perceptible thud. He has had very practical experience with the world around him in such matters as socialized medicine, doctor's draft, veterans' medical problems, malpractice suits, and fee and salary problems. He has seen all types of medical legislation proposed on a national level, vital medical issues weighed on a state level, and health problems thoroughly explored on a local level.

Perhaps because of this probing and intrusiveness, Mr. Average Man no longer idly watches his physician

---

President, Greater Hazleton Chamber of Commerce.

floating on his pink cloud. He expects him to be a citizen as well as a healer. Contrariwise, the physician has perhaps been rudely awakened to the fact that this is so. As Theodore Roosevelt observed, "Every man is, first, a citizen of some community." Our citizenship antedated our professional work and will probably postdate it. As citizens we are, *ipso facto,* deeply interested in our communities, and that is where the chamber of commerce comes in.

OBJECTIVES

A chamber of commerce is an organization that coordinates and integrates the talents and resources of businessmen and professional men trying to make their community a better place in which to live and earn a living. Its programs are dedicated to the improvement of living standards and improvement of the economic condition of all residents, not a favored few. Its entire function is the initiation and support of projects in the public interest. In a real sense, the chamber epitomizes the free enterprise system and the American idea of progress and growth. Its genius lies in organizing and directing the energies of those men in every community who believe that their city has a place in the sun and are determined to find that place. Lord Byron said, "I live not in myself, but become a portion of that around me." The reasons why every American physician should be a portion of his surroundings, and particularly his chamber of commerce, appear self-evident; and yet more than 50% of us are not.

My own interest in our local chamber of commerce began slowly, prodded primarily by the fact that we live in an economically distressed area and that the local chamber, by its own efforts, and by its efforts alone, was bringing new industry into our area. That seemed rather vital to my own livelihood and that of the other professional people in our community. Just how vital? The Chamber of Commerce of the United States, in a most scientific and meticulously accurate survey of nine sample counties throughout the nation, discovered some startling figures concerning the effect of new industrial jobs on a community. They found that just 100 new factory workers meant the following things to their community: 296 more people, 112 more households, 51 more school children, $590,000 more personal income per year, $270,000 more bank deposits, 107 more passenger cars registered, 174 more workers employed, 4 more retail establishments, and $360,000 more retail sales per year.

Stimulated by this knowledge, exactly 100% of our 57 physicians joined the chamber of commerce and so did 75% of our lawyers and 70% of our dentists. After most of us were in, we wondered why physicians everywhere were not. One of us discussed this question on the programs of the 1954 and 1955 annual meetings of the Chamber of Commerce of the United States. At these meetings chamber of commerce executives from throughout the country told us of their particular problems with the physicians in their own areas.

OBJECTIONS AND ANSWERS

The following section is a compilation, as accurately as could be digested, of the objections that physicians in different sections of the country had to membership in their chamber of commerce and just how those of us who are already members would answer these objections:

1. Objection: Costs too much.

Answer: We have also heard a great deal of griping about medical society dues. Such an objection in either case appears passing strange, in view of the fact that each member of the United Automobile Workers pays his union $90 a year in dues and assessments, and other union members pay similar amounts. Comparably, chamber of commerce dues appear inordinately low. The objection itself is not peculiar to the medical profession. It is heard everywhere. The dues vary widely in different localities but usually range between $20 and $50 a year for an individual. That is mighty cheap insurance for the future of your community and, incidentally, yourself. Despite some confusion on the issue, chamber of commerce dues have several times been ruled income-tax deductible by the Internal Revenue Department on the basis that the money is being used for the furtherance of the physician's business. That ruling itself speaks volumes.

2. Objection: It is not professional or ethical.

Answer: Get off that pink cloud. Is it professional to be an isolated clique in the community? Is it ethical to forget that one is a citizen as well as a physician? Chamber membership is not only professional, not only ethical, but distinctly recommended by the American Medical Association through its Public Relations Department.

3. Objection: Too busy.

Answer: All successful men are too busy, but does that mean they should deny their talents to their community? To stoop to a cliché, if you want something done, ask a busy man. If you don't honestly have the time to participate actively, do not withhold your moral and financial support. Your chamber of commerce will handle your share of community betterment and civic duty while you are not available.

4. Objection: The chamber accepts members who are members of the "fringe professions" or even out-and-out quacks.

Answer: Perhaps it does. The chamber will accept anyone who is interested in the betterment of his community. Would it not be considered a sad commentary if the so-called undesirables were interested and the physicians not? And is it better for the fringe professions to speak for the professional group on community problems or the physicians themselves?

5. Objection: Physicians make their contributions to their communities through clinics and charity services and should not be called upon to give more.

Answer: Free work for those unable to pay is our proud heritage and responsibility. Let us not cheapen our heritage by bargaining with it nor shirk our responsibility by underestimating it. As a group we do well enough to support civic affairs actively as well as passively.

6. Objection: Not a democratic organization—run by big business.

Answer: Not so. Chambers of commerce are run in a truly democratic manner. All of the members of a local chamber vote for and elect their board of directors, and the board in turn elects the officers. Local chambers, providing they are members of the national body, also vote for representatives who sit on the board of the Chamber of Commerce of the United States. Anyone really interested is warmly welcomed in chamber of commerce work.

7. Objection: Not a truly local organization—run by an all-powerful United States Chamber of Commerce.

Answer: Again not so. The local chamber is probably the most completely autonomous organization in the community. It carries out its own program in its own way and is answerable only to its own members and the community itself. True, it often calls upon the limitless storehouse of knowledge and experience in the state and national organizations and is sent valuable information by these organizations; but, in the final analysis, all decisions on local, state, or national issues rest with it alone.

8. Objection: Do not like the way it is run locally or the people who run it.

Answer: This answer is obvious. Suppose you do not like your city administration or your elected city officials? You get nowhere by picking up your marbles and going home. Just become a member and give the organization the benefit of your ideas. Critical or otherwise, your voice will always be welcomed.

9. Objection: Do not believe in its policies.

Answer: That is somewhat like saying you do not believe in motherhood or kindness to dumb animals. Simmered down, its policies are basically those of community betterment, the free enterprise system, and the Constitution of the United States.

10. Objection: Do not believe in belonging to other than professional organizations.

Answer: All right, be an ostrich; but remember what has happened in veterans' organizations because of similar unconcern and how we have already succumbed to some of the powerful political lobbies of fringe professions. And much more basically, of course, we must again stress the point of civic responsibility.

11. Objection: Just a bunch of impractical do-gooders, like a Greek letter fraternity.

Answer: That question must be answered locally. It usually means that the work that the chamber has done and is doing is not sufficiently publicized. There is probably not a community in the country that has not been bettered in many ways by its chamber of commerce.

12. Objection: I never got any business, directly or indirectly, from the chamber of commerce.

Answer: This is not a "scratch-my-back-I-scratch-yours" organization. If you buy or sell goods or services in your city, the chamber of commerce is working in your behalf. You obviously make a living, or you would not be here. You must enjoy living in the community, or you would not stay here. No man ever succeeded in any business or profession in the middle of the Sahara Desert. The chamber of commerce is the irrigation system that makes your garden grow.

13. Objection: We can get along without the local chamber and its overhead.

Answer: We can actually get along without any one of the hundred and one typically American organizations where men of good heart voluntarily band together for the common good—but who would want to? This organization is the only one of its kind that is oriented and implemented for community progress. No citizen would admit that his city has reached the saturation point of progress. You probably have not even scratched the surface of possibilities for future growth and prosperity. Business and professional men need an organization for organizing, planning, and thinking. They need a spokesman for their plans. Your chamber of commerce offers just that. And certainly there is an overhead. Nothing can run on the clean air of the city or the good wishes of its inhabitants.

14. Objection: Do not want to be identified publicly with any particular social or ideological group.

Answer: As a group we have been accused at various times of being antiliberal, antilabor, anti-man-on-the-street, and even anti-local business. That is the cross that must be borne in the crusade for progress. Actually the chamber is not anti anything except apathy and indifference and any attempted negation of the American way. If that be ideological identification, then let us make the most of it!

15. Objection: It actually keeps new industry out of our area.

Answer: In economically distressed areas the chamber of commerce is frequently made the whipping boy for all local ills. It is somewhat like blaming Sir Alexander Fleming for a case of pneumonia because his penicillin has not cured it. Obviously, since the chamber is composed almost entirely of businessmen and professional men, its very lifeblood depends on the addition and expansion of new industry in the area.

16. Objection: It attracts too much new industry to our area; we are already overcrowded, strangers are moving in, there are housing problems, labor problems, and parking problems.

Answer: Is there any limit to progress, any ceiling to success? If there are problems connected with progress, solve the problems; do not stop the progress.

17. Objection: The board of directors does not represent the professional viewpoint and commits t organization and sometimes the city to polic
with professional ethics.

Answer: I wish all the answers were
is enough professional participation,
will be any question of variance from

18. Objection: I am too young to afford it (or too old to benefit from it).

Answer: Two variations of the same theme. If you are young and do not have a large income, you nevertheless probably have life insurance. Standing right next to life insurance in importance is community insurance. If the community does not prosper, neither will you. If you are old and cannot see much in the way of personal benefit, think of the older men who preceded you and made the community a better place for you to live.

19. Objection: It is an organization for big business, not the small businessman and individual.

Answer: Quite the contrary. It is just that small person who benefits most from the chamber of commerce. A big business usually has a paid staff to protect its interest, whereas a small business cannot afford similar services except through such an organization. The majority of members in any chamber of commerce are small businessmen or individuals cooperating to accomplish what they cannot accomplish alone. And who profits most from increased local prosperity and civic development—the large industrial plant owner who probably sells 99% of his product elsewhere, or you?

20. Objection: I just do not believe in things like this.

Answer: None.

CONCLUSIONS

There are the objections and the answers. In conclusion, there are three classes of residents in any community: those who live off it, those who live in it, and those who live for it. The first class are parasites, reaping where they do not sow. They are not applicable to this summary, and they beggar description. The second class lives in the community but has little or nothing to do with its activities. If enough of the population are in this group, there is community hari-kari. The third class of residents of a community—those who live for it—recognize their political, social, and economic duties as citizens by taking an attitude of live civic brotherhood. Such men meet on common ground, regardless of professional status, social status, physical possessions, religion, or politics. Let it not be said of the physicians in any community that they abhor this common ground.

INTERIM REPORT, PUBLIC HEALTH SERVICE TECHNICAL COMMITTEE ON POLIOMYELITIS VACCINE

David Bodian, M.D., Thomas Francis Jr., M.D., Carl Larson, M.D., Jonas E. Salk, M.D.
Richard E. Shope, M.D., Joseph E. Smadel, M.D.
and
James A. Shannon, M.D., Chairman

COMMITTEE OBJECTIVES

On May 23, 1955, the surgeon general of the Public Health Service appointed a Technical Committee on Poliomyelitis Vaccine to review production and testing data on lots of vaccine submitted by manufacturers and to make recommendations concerning the release of such vaccine. As a result of an earlier review,[1] it was evident that it would also be necessary for this committee to study the details of manufacturing and testing procedures and to recommend requirements for production that would assure uniformly safe and potent vaccine.

RELEASE OF VACCINE

The significance of a negative test for infective virus on a given lot of vaccine is greatly enhanced if the particular lot is one of a series in which tests for infective virus are negative. This principle was confirmed by observations in the poliomyelitis vaccine field trial. Accordingly, recommendations for release of vaccine by the committee have been influenced as much by the plant record for consistency of performance as by the negative results of tests on the individual lots considered. Consistency of performance, together with a negative test on a particular lot, provides the greatest measure of safety. Observations on field performance of the vaccine in the United States, Canada, and Denmark during 1955 have fully supported this concept.

INVESTIGATION OF VACCINE MANUFACTURING AND TESTING METHODS

The committee has been in operation for more than five months. During this time it has met repeatedly with manufacturers' technical representatives. With their cooperation the committee has investigated the important aspects of vaccine processing and testing. This report contains a summary account of the information obtained and the decisions reached. Although it is not possible to present here the voluminous data that have become available or to evaluate such information in detail, this summary may be useful in informing the medical profession and the public of the present state of the problems with which the committee has been concerned. Fuller technical accounts dealing with the separate subjects to which reference is made will be submitted for publication in *Public Health Reports* or other scientific journals.

EXPLANATION OF THE PROBLEM OF CONSISTENCY IN MANUFACTURE

The committee sought information bearing on the question of lack of consistency in production of vaccine by some manufacturers. Since the observed inconsistencies were not of the same order of magnitude in the case of all manufacturers—in fact, it could be said that the operation of the inactivation process was highly consistent in some laboratories—it was clear that the establishment of an equally consistent record of negative tests by all manufacturers would necessitate an analysis of differences in manufacturing details.

---

[1] Technical Report on Salk Poliomyelitis Vaccine, U. S. Public Health Service, June, 1955.

In the case of those manufacturers whose process lacked the desired degree of consistency, it appeared that, in the early phase of inactivation, virus was being destroyed as rapidly and as uniformly as was expected. In some instances, however, there were traces of infectious virus that resisted treatment that theoretically was capable of inactivating much greater amounts of virus. This conclusion was evident from the results of the testing practices that were in effect before as well as after May 26, when the requirement for volume of sampling was changed. Moreover, such traces of active virus, in many instances, were not eliminated by the application of still further treatment. This was true for all three types of virus.

In considering reasons for failure of complete inactivation, it seemed that such failure could be due either to protection of virus from direct contact with formaldehyde or to the existence of virus particles that are inherently more resistant to formaldehyde. There is no evidence for the latter possibility. Rather, the facts support the concept that a physical barrier interfered with the contact required for chemical interaction between formaldehyde and the virus. The fact that failure of complete inactivation was not an industry-wide problem could also be interpreted to mean that details of manufacturing were at fault rather than the ineffectiveness of formaldehyde as a means for destroying virus infectivity in suitably performed routine vaccine manufacture.

In searching for the significant technical factors that might be operative, plant processes were reviewed and an examination was made of representative samples of virus-containing fluids prepared for the inactivation step by the different manufacturers. Although differences in details of processing were recognized in the review of plant procedures and certain conclusions could be reached therefrom, the significance of these differences became more apparent when studies were made of virus fluids prepared for inactivation by each of the manufacturers. The striking differences observed were in the degree of clarity of the different fluids and in the character of the sediments that were present in some. It was noted, also, that fluids that contained sediments failed to inactivate under conditions applied simultaneously and effectively to other fluids not having such sediments. This observation pointed strongly to a solid phase as the source of the physical barrier against complete interaction between virus and formaldehyde. Virus incorporated within a solid phase should not be expected to be inactivated in the same way as virus free in the fluid phase; in fact, it was for this reason that filtration was required from the beginning as a step in the procedure for vaccine manufacture. Unfortunately, the importance of uniform standards of filtration in large-scale production could not be fully appreciated until the difficulties resulting from departures from former production methods became known to the controlling agency.

In searching further, it was found that fluids that failed to be inactivated often had not been filtered just before addition of formaldehyde but had been filtered a number of months earlier. This made it difficult to decide, in some instances, whether the solid phase was formed on standing, whether it was due to material that passed through a defective filtration process, or whether it was due to both factors. It was evident, nevertheless, that such practices as would permit the existence of a solid phase could account for the occurrence of inconsistency of inactivation. It was not possible in most cases to evaluate the relative importance of inadequacy of filtration as compared with storage after filtration.

The idea that inadequacy of filtration, even without the influence of storage, might be responsible for the existence of "protected virus" was suggested by several observations. First, inconsistencies encountered seemed to be associated with the use of fritted glass filters. However, it was also evident, from a considerable body of experience, that fritted glass filters could be used satisfactorily. Second, the kind of inconsistency observed was not encountered by laboratories when Seitz-type filters were used, nor was it encountered in the preparation of vaccine for the field trial when Seitz-type filters for the most part were used.

CURRENT FILTRATION AND INACTIVATION REQUIREMENTS

Physical homogeneity as a necessary prerequisite for satisfactory inactivation can be approximated by requiring the application of proper filtration procedures in fixed time relationships to the inactivation process. This is being done by requiring that (1) the preinactivation filtration be carried out not longer than 72 hours prior to initiating the formaldehyde treatment, and (2) a second filtration be carried out during the inactivation process, at the time when infectivity is reduced to a point at or below the minimally detectable level, and several days prior to the taking of the first 500 ml. safety-test sample. By these practices, the degree of physical homogeneity required for a consistently reproducible process is maintained. Precipitates or aggregates above a certain size are eliminated both before formaldehyde treatment is begun and again during the process and prior to termination of the inactivation procedure.

The type of filter to be employed, the number required, and the maximal volumes to be passed in order to provide the kind of assurance desired have been specified in the current requirements. The purpose of these steps is to provide assurance of effective contact between the virus particles in suspension and formaldehyde throughout the inactivation process. Approximately a one-million-fold reduction in infectivity titer is effected in any two to three-day period, and filtration in the course of processing is to be performed sometime between the third and sixth day of formaldehyde treatment. Therefore, any virus released from crystalline or amorphous precipitates, or disaggregated during the last filtration, will still be exposed to an inactivating force of at least three days of formaldehyde treatment. The absence of particles greater in size than can pass the filtration procedure prescribed is considered to be the key to consistently complete inactivation.

If any manufacturer wishes to introduce additional filtration steps beyond those prescribed, or additional treatments that have virucidal effects, these, too, may be employed. But it should not be expected that such additional treatments would create greater safety, since complete inactivation is probably more dependent on the absence of protected virus in aggregates than on the particular inactivating method employed.

TISSUE CULTURE SAFETY TESTS

Subsequent to the last filtration, and at a point in time when it may be presumed that virus infectivity is destroyed—usually six to nine days—a sample is removed from each container in which virus is being inactivated and 500 ml. is tested in tissue culture. It is necessary not only that this sample be free of demonstrable infective virus but that this also be true of a second similar sample that is removed after continued exposure to formaldehyde for an additional three days. With the elimination of particles of the size that will be retained by the filtration procedure prescribed, it may be presumed that, during the additional three-day period, the inactivating effect of the formaldehyde will be the same as that during the first three-day period of treatment, when the rate of inactivation is determined for each lot being tested.

If any sample is found to contain live virus after the application of formaldehyde for a period of time equal to three times the period required to reduce infectivity to just perceptible levels, the prescribed filtration is repeated. Subsequently there must be negative tests for virus on two 500 ml. samples removed three days apart in the course of further processing. If the additional treatment is not successful, a review of the manufacturing process is indicated.

After the two negative tests on 500 ml. samples of the monovalent pools, a trivalent mixture is made and this is also tested in tissue culture, with use of a 1,500 ml. sample. In addition to the specific information required on each lot of vaccine, a continuous record is kept of the outcome of each monovalent strain pool started in each plant, and of each trivalent vaccine pool, to ascertain consistency of performance. A continuing record of the sensitivity of tissue culture tests for the detection of minimal amounts of virus is also maintained. The release of vaccine is contingent upon an analysis of information, not only from each individual lot but from the plant record as well.

MONKEY SAFETY TEST

A further test of safety is made by inoculation of monkeys. The monkey safety test has been shifted from its previous position, where it was applied to the trivalent pool, and has now been adapted for use as the final container test. It is required that a minimum of 5 monkeys be inoculated with samplings of each filling lot and that there be a minimum of 25 monkeys for each manufacturing lot from which these fillings are derived.

Tests made on these animals include tests for potential susceptibility, which requires the demonstration of the absence of circulating antibody in the serum prior to inoculation. In addition, samples of spinal cord segments are removed after 18 days, not only for histological study but also to permit attempts at virus isolation in those cases that are suggestively positive histologically. The need for material for virus isolation attempts arises from the observation that in a number of instances a vaccine lot was considered positive for poliomyelitis virus on the basis of questionable histological findings. The evidence now indicates that such lesions may have been due to a recent or remote encephalitis infection acquired before the test procedure and that some vaccine was discarded that would have been safe for use.

It is now evident that under usual circumstances the monkey safety test is less sensitive than the tissue culture tests prescribed—because the volume that can be tested in tissue culture is greater, and because the strains of virus included in the vaccine are less infective in monkeys than in tissue culture. However, an effort has been made to increase the sensitivity of the monkey test by increasing the susceptibility of the test animal, by increasing the number of monkeys used, and by injecting each animal with vaccine not only intracerebrally but intraspinally and intramuscularly as well.

As an additional safety test, conducted to establish the effect of vaccine administration via the route usually used in man, 12 monkeys are inoculated intramuscularly, each with 3 ml. of undiluted vaccine given in divided doses and at weekly intervals. These monkeys were formerly considered only as part of the potency test but now can be considered as an integral part of the monkey safety-testing scheme. They now receive an additional intracerebral injection and are studied histologically for evidence of lesions in the spinal cord.

POTENCY TESTS

Although the present potency tests and criteria are satisfactory for practical purposes, studies are being made to determine the best methods for increasing the discriminatory power of the test. However, the principle will remain the same, in that a reference vaccine will continue to be used. The potency of this reference standard has been established by test in children who have no antibodies for any of the three types.

A number of suggestions have been made for using different animals or different test plans for establishing potency. The most rational approach is to use a reference vaccine standardized for its performance in children, as is now in effect. Therefore, the problem is one of level of acceptability and of technique for establishing the relationship to the standard of reference. These questions are still under study and will be evaluated as comparisons can be made of the relative potencies of the vaccines used this past summer and their performance in the heavily epidemic areas.

STRAIN COMPOSITION

It is the opinion of the committee that vaccine properly made by the present methods with the Mahoney strain provides an entirely safe immunizing agent. Nevertheless, a change in the type 1 strain is being considered to find a less virulent strain with equal or better immunizing capacity, stability, filterability, and other characteristics of importance in manufacturing.

This subject has been under investigation in a number of laboratories, and it is now evident that there has as yet not been found any type 1 strain that is truly "avirulent" for monkeys when given to adequate numbers of monkeys in the form of undiluted tissue culture fluid, and by all routes, including the intramuscular. Twelve strains of type 1 virus, furnished by investigators particularly interested in this problem, have been shown now to be of relatively low virulence. However, it still remains to be demonstrated whether any type 1 strains can be considered as completely avirulent when tested in a stringent manner. The present type 2 and 3 strains are in the category of strains of lesser virulence and seem to be less active in producing disease in monkeys than a number of selected type 1 strains that are in the category referred to as "avirulent" or "attenuated."

A study that has required more than a year for completion has revealed that antigenic capacity of equivalent degree is found in a number of the type 1 strains that are characterized by low virulence for the monkey. The problems that now remain to be resolved are those related to suitability for use in production, such as filterability, and especially the question of stability in the presence of the preservatives used.

In addition, information will be required on the resistance of monkeys vaccinated with any new strain to challenge with Mahoney, since field experience has been with a virus containing the latter strain. Information obtained from these studies will permit a decision on the advisability of substituting another type 1 strain for the present Mahoney strain. If another strain is established as superior to Mahoney, it should not be expected that it can be included in commercially distributed vaccine before the 1956 poliomyelitis season. The time when this will be possible cannot be determined at the present time.

SUMMARY

The Technical Committee on Poliomyelitis Vaccine is of the opinion that the principal factors that were involved in earlier manufacturing and testing difficulties have been identified and corrective measures have been taken. Among these factors is the absolute need for removal of particles within which virus may be protected from inactivation by formaldehyde. Provisions have been made to insure as far as possible the removal of such protected particles by suitably spaced filtration procedures. In addition, the safety-test program has been strengthened by improved sampling procedures in the tissue culture tests and by increasing the sensitivity of the monkey safety tests. These measures, together with continuous review of plant production records, assure the safety of released vaccine and should make possible an increased availability of vaccine.

Population Trends.—If the birth rate continues at its present high level, the population of our country will pass the 200 million mark before 1970 and will exceed 220 million by 1975. . . . Currently, there are almost 60,000,000 people in our country under age 20 and nearly the same number at ages 20-44; somewhat more than half that number—about 33,000,000—are in the age range 45-64, and not far from 14,000,000 are at ages 65 and over. Each of these groups will increase, with the most rapid growth expected at the younger and the older ages. . . . The sex ratio as well as the age composition of the population is expected to change in the years to come. . . . Females outnumbered males for the first time in the Census of 1950, but by only 1%. This margin, it is estimated, will grow to 3% by 1975. This trend will reflect the rapid rise in the excess of females over males at the ages 45 and over. At ages 45-64, females will exceed males by more than 10% in 1975; at ages 65 and over, the excess will be about 40%.—Future Population Trends, *Statistical Bulletin*, Metropolitan Life Insurance Company, March, 1955.

CLINICAL NOTES

ORAL THERAPY OF ADRENAL CORTICAL HYPOFUNCTION

USE OF COMBINED FLUDROCORTISONE ACETATE AND HYDROCORTISONE

Herbert S. Kupperman, M.D., Ph.D.
and
Jeanne A. Epstein, M.D., New York

The treatment of adrenal cortical hypofunction (Addison's disease) has evolved from the fairly unpredictable precarious control of the patient by the use of oral ingestion of high doses of sodium chloride to a more precise, effective, physiological management based on the use of intramuscular administration of desoxycorticosterone acetate in oil. Pellet implantation of the same steroid soon led to even more exact control of adrenal cortical hypofunction with less frequent administration of the necessary steroid. Infrequent intramuscular therapy has been achieved more recently by administration of aqueous suspensions of other esters of desoxycorticosterone; in particular, the trimethylacetate derivative, which has been used with success, may be administered only once every four weeks in most patients.[1] The use of desoxycorticosterone trimethylacetate, plus supplementary oral therapy with cortisone, until recently, has resulted in optimum therapeutic control of most patients with adrenal cortical hypofunction. The use of oral therapy involving cortisone alone yielded incomplete electrolyte regulation in most patients, although the carbohydrate disturbances were adequately controlled in all. In an attempt to overcome the need for parenteral administration of desoxycorticosterone acetate in the patient with adrenal cortical hypofunction, this substance has been employed in lingual form.[2] In adequate dosage, sublingually given desoxycorticosterone with cortisone given orally has resulted in the satisfactory management of some patients with adrenal cortical hypofunction. The sublingual route of administration gives variable therapeutic results, believed to be due to faulty or irregular sublingual absorption and inability of the patient to prevent most of the active material from being washed down the stomach by salivary secretion.

In an attempt to accomplish effective, well-controlled maintenance of patients with adrenal cortical hypofunction, with less frequent oral administration, fludrocortisone acetate (9-α-fluorohydrocortisone) has been administered to patients with primary and secondary adrenal cortical hypofunction.[3] The recent studies using fludrocortisone acetate have indicated that in addition to its antiphlogistic and corticotropin (ACTH)-inhibitory

[2] Meier, R.; Gysel, H., and Mueller, R.: Die Wirkung des Desoxycorticosteronglucosids (Percorten Z. G.) auf die Nebenniereninsuffizienz, Schweiz. med. Wchnschr. 74:93 (Jan.) 1944.

properties, this compound may induce sodium retention when administered orally or applied topically.[4] Our preliminary studies with this compound in patients with the adrenogenital syndrome showed that in addition to effective inhibition of endogenous corticotropin secretion in doses of 2 to 3 mg. per day fludrocortisone acetate also produced the undesirable effect of profound sodium retention in these patients.[5] Thus, the marked oral effectiveness of the drug in inducing sodium retention and the accompanying edema gave promise for its use in the oral control of patients with adrenal cortical hypofunction. Fludrocortisone acetate together with hydrocortisone has been administered orally to six patients with adrenal cortical hypofunction. Four of these patients were diagnosed as having primary adrenal cortical hypofunction; three due to idiopathic adrenal cortical failure and one as a result of adrenal cortical hypofunction following total adrenalectomy for adrenal cortical hyperfunction (Cushing's syndrome). The remaining two patients have adrenal cortical hypofunction secondary to pituitary failure; one has pituitary insufficiency following radiation therapy for acromegaly and the other secondary to a suprasellar neoplasm. All patients have been maintained on hydrocortisone administered in doses of 10 mg. twice a day and fludrocortisone acetate administered in doses of 0.25 mg. every other day. The control of the patients with oral administration of these two drugs has been accomplished with ease (see table). Adequate control has been achieved for periods of 6 to 14 months. Two of these patients had previously been well maintained on 50 mg. of desoxycorticosterone trimethylacetate administered every fourth week. The effectiveness of the medication has been repeatedly demonstrated by the fact that, when the dose of fludrocortisone acetate was discontinued, adrenal cortical hypofunction of a severe nature intervened within 7 to 14 days after the ingestion of the last dose. Reversal of this induced adrenal cortical hypofunction was readily accomplished upon reinstituting larger oral doses of fludrocortisone, in the range of 0.5 to 1.0 mg. per day, for three to four days.

Control of Adrenal Cortical Hypofunction with Fludrocortisone Acetate and Hydrocortisone†*

Case No.	Age, Yr.	Sex	Diagnosis	Duration of Treatment, Mo.	Previous Therapy
1	29	F	Secondary adrenal cortical hypofunction (suprasellar neoplasm)	7	None
2	45	F	Primary adrenal cortical hypofunction	13	Desoxycorticosterone trimethylacetate, 50 mg. every mo.; *cortisone, 20 mg. every day*
3	60	M	Secondary adrenal cortical hypofunction; pituitary irradiation	7	Desoxycorticosterone trimethylacetate, 25 to 37.5 mg. every mo.
4	50	M	Primary adrenal cortical hypofunction	6	Desoxycorticosterone acetate, 2.5 mg. every day
5	29	F	Adrenalectomy for adrenal cortical hyperfunction (Cushing's syndrome)	14	Cortisone, 12.5 mg. twice daily
6	39	M	Primary adrenal cortical hypofunction	12	Desoxycorticosterone trimethylacetate, 50 mg. every 4 to 5 wk.; cortisone, 10 mg. twice daily

* 0.25 mg. given every other day.
† 10 mg. given twice a day.

The derivation of the dose of fludrocortisone was based upon the effectiveness of this steroid in controlling symptoms of adrenal insufficiency and in avoiding manifestations of overdosage using the following three clinical guides: (1) weight gain, (2) the presence of edema, and (3) alteration in blood pressure. Using these three criteria, evidence of overtreatment or inadequate therapy is readily apparent. The dose of fludrocortisone acetate is then promptly and easily altered so that the deviation from the normal is adequately corrected.

Evidence of overdosage with the halogenated steroid occurred when 0.5 mg. of fludrocortisone acetate was administered every day and was characterized by the usual classical disturbances noted after desoxycorticosterone overdosage. These included edema, headache, hypertension, weight gain, and cardiac enlargement. It should be mentioned, however, that these untoward reactions were readily dissipated within three to five days merely by discontinuing treatment with the drug.

The therapeutic range for fludrocortisone acetate, while admittedly small, was sufficient to permit precise management of all patients with adrenal cortical hypofunction. While 0.25 mg. of fludrocortisone acetate administered every other day adequately controlled all the patients, the same dose administered daily invariably produced the overdosage effects outlined above within a period of five to eight days. Discontinuing the dose for three to five days and then resuming the average maintenance dose of 0.25 mg. every other day resulted in subsidence of toxic reaction followed by adequate maintenance in all. It should be noted that one patient, a 50-year-old Negro male (table, case 4), with adrenal cortical hypofunction and evidence of decreased glucose tolerance, was adequately maintained on the dose regimen described above for a period of five to six months with excellent therapeutic effectiveness. Prior to the oral use of medication, this patient required daily intramuscular administration of desoxycorticosterone acetate. However, since he took the parenteral therapy intermittently he was usually under inadequate control and exhibited at times all the signs of moderate adrenal cortical hypofunction. These were characterized by intermittent fainting spells, weakness, and tiredness. Since the patient

has been maintained on therapy orally none of these untoward sequelae have been noted, inasmuch as he has found it convenient to maintain himself as directed and the discomfort of daily injections has been obviated by the oral therapy. It is interesting to note that the increased pigmentation previously observed in this patient had decreased considerably while the patient was receiving the combined halogenated steroid and hydrocortisone therapy.

SUMMARY

The effectiveness of fludrocortisone acetate (9-α-fluorohydrocortisone) and hydrocortisone given orally in the recommended doses proved to be an effective means of controlling patients with adrenal cortical hypofunction (Addison's disease), due to idiopathic insufficiency, surgical ablation, adrenal cortical atrophy, or secondary to pituitary insufficiency. All the patients who have been observed on this combined therapy were adequately controlled, were easily maintained, and showed no signs of hypernatremia when the recommended doses were employed. The method lends itself well to the management of adrenal cortical hypofunction, since there is no pain or inconvenience associated with administration, flexibility of dose is easily accomplished, and steady control of the patient is easily attained without noticeable fluctuation in symptoms of fatigability and muscular weakness.

550 First Ave. (16) (Dr. Kupperman).

USE OF THE IMAGE AMPLIFIER IN CARDIOVASCULAR DIAGNOSIS

Henry A. Zimmerman, M.D., Cleveland

The image amplifier allows one to do fluoroscopy in a lighted room, thereby allowing one to use cone vision rather than rod vision. This does away with the prolonged period of time, 15 to 30 minutes, it takes to secure full rod vision to see clearly detail in the present Patterson 2 B type of fluoroscopic screen. In theory the Fluorex image amplifier is an electronic vacuum tube and works as follows (fig. 1): X-rays, when they are generated by the x-ray tube, pass through the patient and then, in the ordinary fluoroscope, hinge upon the fluoroscopic screen. With the image amplifier, these rays, as they emerge from the patient, are collected on a 5 in. fluorescent screen located just within the inner surface of the glass vacuum image amplifier tube. In close contact with the fluorescent screen is a photoelectric surface. Light produced on the screen by the x-rays is converted into an electronic image surface by the photoelectric surface. Then, by a series of lenses, the electronic image is focused, and, by applying a potential of 30,000 volts, the electrons are accelerated towards the aluminum back phospholayer, which is 1 in. in diameter. At this screen the electrons arrive with increased velocity and are condensed into a smaller area. The resulting image on the output phosphor has been increased in brightness by 200 times that originally produced on the input fluorescent screen. The image is then viewed in true orientation to the patient undergoing examination by the optical system. Regardless of the position of the viewing system, one always sees the image in the same relationship to the patient. Figure 2 shows the optical system in a schematic way.

In my experience, the only disadvantage to this system is the 5 in. area or field that can be viewed at any one time. However, as one gains experience with the instrument, this becomes a minor objection. With the use of the image amplifier the irradiation to the patient and to the personnel can be markedly reduced. This is brought about by reduction in the tube current due to the intense brightness from the image amplification. Usually, good visualization can be obtained at 70 kv. with 2 ma. Either a single-view or a double-view mirror can be used to view the resulting image. With the single-view mirror only one person can view the image at a time.

With the intensity of brightness of the image amplifier one is able to photograph directly from the viewing mirror an image that can be easily photographed. I have been taking movies of the screen showing the beating of the heart, as well as pictures of the aorta, the lung fields, and the pulmonary vascular tree. In early 1956, I have been told, the Westinghouse Corporation will market a camera that will be housed directly in the lens system and will give better motion pictures of the beating heart and vessel pulsations. This should make angiocardiography a fascinating, helpful, and useful method of examination, as 36 or 72 frames per second can be taken as compared to the one or two pictures per second that can now be taken with the automatic cassette changer or automatic camera.

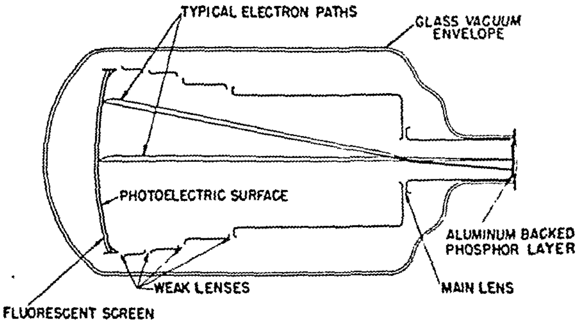

Fig. 1.—Schematic drawing of component parts of the Fluorex amplifying tube.

ADVANTAGES

I have found the image amplifier is a major advance in the technique of intracardiac catheterization, and, with personal experience with over 1,000 intracardiac catheterizations done with the conventional fluoroscope, I can say that the image amplifier is a major advance in the technique in instrumentation of doing intracardiac catheterizations. It allows one to see the catheter tip at all times, and this is true even in large hearts where, with the conventional system of fluoroscopy, many times the catheter tip was lost from view. This is especially true when the catheter crosses the vertebral bodies. It also

---

Director of the Marie E. Coakley Cardiovascular Laboratory and Director of the Cardiovascular Section, Division of Medicine, Saint Vincent's Charity Hospital.

gives an excellent picture of the position of the catheter in intra-atrial septal and interventricular septal defects. With the use of the image amplifier one actually gets a three-dimensional effect when viewing the catheter, and one can tell exactly whether the catheter is pointing to the side, anteriorly, or posteriorly. This is a difficult task to ascertain, in fact almost impossible under the conventional fluoroscope. One can clearly see the catheter in the lung structures as well. With the catheter in the heart one is able to see clearly the extent of infundibular stenosis by correlating the movement of the catheter with pressure tracings taken simultaneously. Another great advantage of the image amplifier in doing cardiac catheterization as far as the patient is concerned is that he is not put in a dark or light-proof room, and, consequently, much of the fear and apprehension caused by the procedure is done away with. Figure 3 shows an image amplifier unit installed in the cardiovascular laboratory.

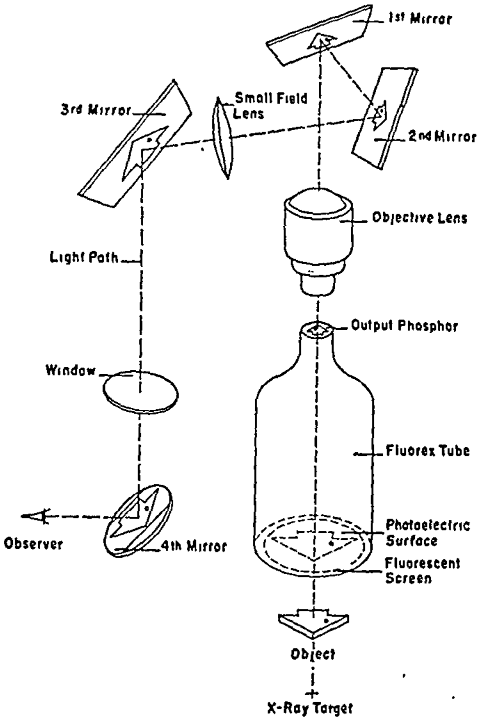

Fig. 2.—Schematic drawing of optical system of image amplifier.

Calcification in the ring or in the aortic or mitral valve cusps can actually be visualized with the image amplifier. This has always been a difficult, if not impossible, thing to determine with routine fluoroscopy; and, unless a special technique is used, it is difficult to photograph on an x-ray film. Calcification in the coronary arteries can actually be seen at times, as can calcifications in the wall of the myocardium as seen in healed infarctions of the myocardium. Another use of the image amplifier is to determine the amount, if any, of pulsation and the type of pulsation of the heart, and ventricular aneurysms are much more easily recognized and studied by this method. By varying the kilovoltage and the milliamperage a great deal of contrast can be obtained and the pulsations can be seen and can be readily studied. The old problem of whether pulsation is extrinsic or intrinsic is much more simple to resolve. A man, aged 40, was found to have a suggestive bulge on his left midcardiac border. On viewing this area under the image amplifier, distinct paradoxical pulsations could be seen. The diagnosis of an aneurysm of the left ventricle was readily made. A movie of this pulsation was taken for additional study and permanent record.

Another difficult problem made much easier or resolved by the image amplifier is the determination of pulsations in the pulmonary arteries and in the pulmonary circulation. This, many times, is a crucial point in an infant or a young child in telling whether the vascularity to the lungs is normal, decreased, or increased. This has been a rather simple and easy differentiation to make with the use of the image amplifier, as one can actually clearly see the pulsations and the vigorous indentation of the pulmonary artery. The problem of a pulmonary arterial venous aneurysm in the lungs can be definitely illuminated by direct visualization. Also, in isolated tumors or nodules in the lung, the problem of intrinsic and extrinsic pulsation can usually be resolved quite easily with the image amplifier. Recently a physician, aged 38, had acute chest pain after an auto accident. A chest x-ray showed a mass in the area of the pulmonary artery in the left lobar area. This was interpreted on fluoroscopy, by the radiologist, as an aneurysm of the pulmonary artery. Visualization by the image amplifier showed what appeared to be a cyst with no intrinsic pulsations. Angiocardiography was carried out and proved the mass to be nonvascular. At operation a cyst of the thymus was found and removed. This shows how well one can see with the aid of the image amplifier. Calcium in the ascending aorta in syphilitic aortitis and in the knob of the aorta in arteriosclerosis of the aorta is quite easily delineated and studied.

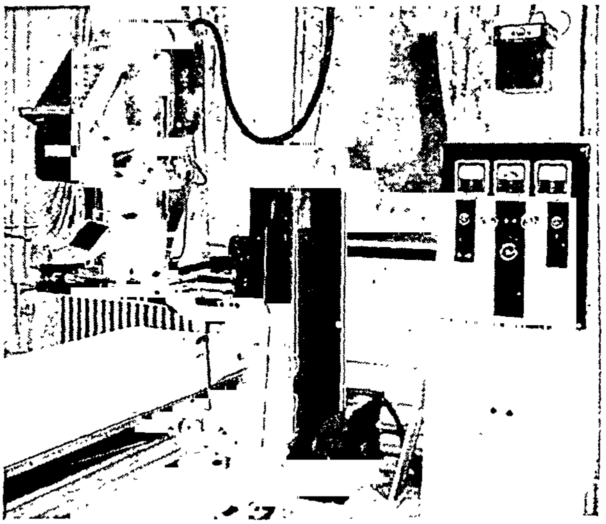

Fig. 3.—Instillation of image amplifier in the cardiovascular laboratory. Note double-view mirror that allows two people to view image at the same time.

SUMMARY

The image amplifier represents a definite advancement in the diagnosis of cardiovascular disease. It allows the use of cone vision, lessens the exposure of the personnel and of the patient to radiation, allows one to carry out intracardiac catheterization with complete vision of the catheter at all times, allows one to determine the extent and the magnitude of pulmonary blood flow, makes for the easy detection of calcium in the aortic and mitral valves, clarifies the problem of extrinsic and intrinsic pulsations in nodules or masses in the lungs and their difference from vascular lesions, and allows taking of motion pictures of the visualized pathology for more detailed studies.

250 Hanna Bldg. (15).

POCKET MEDICAL KIT

Harry E. Barnett, M.D., Chicago

A light-weight pocket-sized medical kit that contains a selection of closely fitted diagnostic instruments, therapeutic equipment, and medicaments has been assembled. Originally planned for orthopedic surgeons, the kit has been modified so that it can be used by general practitioners, as well as by various types of specialists, as an auxiliary "doctor's bag" or as an emergency kit. It may be useful in routine practice and should be especially valuable for unexpected emergencies.

The leather case (fig. 1) is 5 by 4.5 by 0.75 in., weighs 14.5 oz. when fully outfitted, and contains the following items: (1) steel knife with 2.5 in. blade (fig. 1*A*) in which the knife also serves as a handle for the screwdriver, file, and reflex hammer, which are attached to it by a spring-locking mechanism; (2) a plastic ruler, with a magnifying lens and a flat surface that can be used as a tongue blade (fig. 1*B*), which is 3 in. long and is graduated in inches and centimeters; (3) screwdriver and file (fig. 1*C*), which attach to handle of knife; (4) metal case containing 1 cc. syringe and needle (fig. 1*D*), which may be sterilized and kept covered by a rubber or metal cap; (5) reflex hammer (fig. 1*E*), which inserts into the knife handle to form an adequately weighted and properly balanced instrument (fig. 2*A*) and in which a pin is also contained, readily available for testing sensation, magnetized for use in removing metallic foreign bodies, and equipped with a thin metal ledge underneath for spreading casts; (6) two 1 cc. ampuls of medicaments for injection (fig. 1*F*), such as ephedrine sulfate and morphine sulfate; (7) single cell battery flashlight (fig. 1*G*) in which mercury batteries may be used for longer battery life; (8) steel case with 42 in. cloth tape measure on pushbutton spring return mechanism (fig. 1*H*); (9) stethoscope diaphragm (fig. 1*I*) from which a monaural stethoscope (fig. 2*B*) may be formed by attaching the diaphragm to the rubber tubing with its adapter and earpiece (fig. 1*Q*); (10) disposable cartridge containing 600,000 units of penicillin in aqueous suspension, with covered sterile needle (fig. 1*J*) with which the thermometer case (fig. 1*R*) is used as a plunger for intramuscular injections (fig. 2*C*); (11) perle of aromatic ammonia (fig. 1*K*); (12) two plastic vials with cork stoppers (fig. 1*L*) for orally or hypodermically administered medicaments such as codeine sulfate and morphine sulfate tablets; (13) 3 in. tissue forceps (fig. 1*M*); (14) 4.75 in. scissors (fig. 1*N*) with blunt and pointed ends for removing bandages or sutures; (15) ballpoint pen (fig. 1*O*) that can also be used as a skin-marking pencil; (16) black silk suture material and 2.5 in. straight-cutting needle contained in a sterile packet (fig. 1*P*) or in a sterile glass vial; (17) rubber tubing (fig. 1*Q*), which can be used as a tourniquet, and, with the earpiece and the metal adapter at its opposite ends, it forms a part of the monaural stethoscope (fig. 2*B*); and (18) thermometer in a metal case (fig. 1*R*) that is also used as a plunger for the penicillin tube (fig. 2*C*).

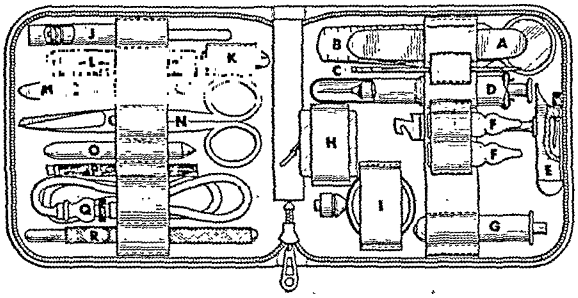

Fig. 1.—Pocket medical kit opened to show arrangement of contents. *A*, steel pocket knife; *B*, plastic ruler with magnifying lens and tongue blade (steel ruler and goniometer may be substituted); *C*, screwdriver and file; *D*, syringe and needle in metal case; *E*, reflex hammer and pin; *F*, ampuls; *G*, flashlight; *H*, tape measure (container for additional medicaments or nasal and aural speculums may be substituted); *I*, stethoscope diaphragm; *J*, disposable cartridge of penicillin (large vial for medicaments or a hemostatic forceps may be substituted); *K*, aromatic spirits of ammonia; *L*, two plastic vials for medicaments; *M*, 3 in. tissue forceps; *N*, scissors; *O*, ballpoint pen; *P*, sterile needle and suture material; *Q*, rubber tubing with earpiece and adapter for stethoscope diaphragm; and *R*, thermometer in metal case.

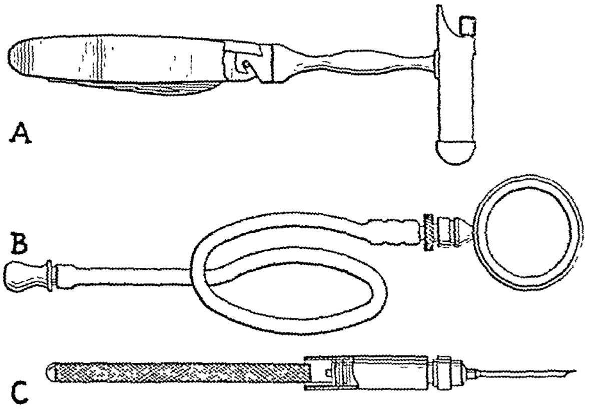

Fig. 2.—Assembled instruments. *A*, handle of knife also serves as handle of reflex hammer Screwdriver-file attaches in similar manner. *B*, rubber tubing with earpiece and adapter forms monaural stethoscope when attached to diaphragm and may also be used as a tourniquet. *C*, metal thermometer case is used as plunger for disposable penicillin cartridge.

The inside of the leather case is stamped with the outlines of the contents to facilitate reinsertion of the various items into the proper compartments. A zipper encircles three sides of the leather case, and closure is accomplished with speed and ease. The kit is sufficiently compact so that it may be carried at all times in the back trousers pocket or in a coat pocket, in much the same way that a wallet or a pocket secretary is carried. Women physicians may carry it in a handbag. By having the kit

---

From Michael Reese Hospital.

The pocket medical kit may be assembled by obtaining the proper size leather case and the suggested instruments and vials from surgical or hospital supply companies. The thermometer case, reflex hammer, syringe case, and magnifying lens-ruler have been especially designed for this kit and may be ordered from V. Mueller and Company. The entire kit will be assembled under the name "Pocket Medikit" and may be obtained from V. Mueller and Company, Chicago.

available at all times the physician is prepared for unexpected medical emergencies away from the hospital and office, e. g., at home, on vacations, and at social or sporting events. The contents of the kit may be varied, in keeping with the specialty of the physician. The measuring tape may be replaced by a metal container for additional medicaments or by a nasal and aural speculum. The plastic ruler and magnifying lens may be replaced by a combination steel ruler and goniometer. The ruler is graduated to 4 in., and the goniometer has a range of 180 degrees. The penicillin ampul may be replaced by a large vial for tablets or capsules or by an instrument such as a tuning fork or a hemostatic forceps.

The diagnostic instruments in the kit enable the physician to test sensation and tendon and pupillary reflexes and to measure joint motions, lengths of extremities, and circumference of head and limbs without need for additional apparatus. The bandage scissors is frequently used in hospital rounds, and its availability eliminates the need for the frequent requests that are made for this instrument from hospital nurses. For painful injuries and ailments, the codeine or morphine may be given orally or hypodermically at the time of initial examination or treatment in the home, office, or hospital outpatient department. Sufficient orally administered medicaments may also be left with the patient for relief of symptoms until a prescription can be filled. This is especially important in areas where pharmacies are closed throughout the night. Minor lacerations may be sutured away from the hospital or office by means of the needle, black silk, tissue forceps, and scissors. The monaural stethoscope is efficient in transmitting heart and lung sounds. A rubber earpiece provides better holding power with less possible trauma within the external ear canal. In a noisy room the other ear may be closed by inserting the tip of the finger. The availability of the monaural stethoscope may encourage its more frequent use by physicians who ordinarily do not carry this instrument. A pocket can be added to the outside of the kit to hold a few prescription blanks and important charts, such as antidotes for poisons and dosages of newer drugs.

SUMMARY

A pocket medical kit that contains 24 essential and frequently used diagnostic and therapeutic instruments and medicaments is designed for use by physicians in general practice and in various specialties. Light in weight and compact in size, it can be carried in a pocket, handbag, or glove compartment of a car. Its usefulness to the physician in routine practice and in unexpected emergencies is enhanced by the ease with which it may be carried at all times.

116 S. Michigan Ave.

Radioactive Iodine in Hyperthyroidism.—The use of radioactive iodine in treating patients with hyperthyroidism is based upon two facts: 1. The natural avidity that the thyroid has for collecting iodine, either stable or radioactive. 2. Within the thyroid the radioactive iodine decays by emitting high energy beta rays which penetrate only a few millimeters into the tissue; beta rays act the same as the secondary electrons which are produced by roentgen rays and serve to destroy tissue.—E. M. Chapman, M.D., and Farahe Maloof, M.D., The Use of Radioactive Iodine in the Diagnosis and Treatment of Hyperthyroidism: Ten Years' Experience, *Medicine,* September, 1955.

SPECIAL ARTICLE

HAZARDS OF MODERN DIAGNOSIS AND THERAPY—THE PRICE WE PAY

FRANK BILLINGS MEMORIAL LECTURE

David P. Barr, M.D., New York

"First of all, be sure you do no harm: *Primum non nocere.*" In all ages this admonition has been fundamental to the practice of medicine. It applied to the use of all the empirical drugs of ancient and medieval times. Failure to regard it inspired the scathing satires of Molière and was responsible for the research of Pierre Louis and the reforms of Oliver Wendell Holmes and Ignaz Semmelweis. The admonition applied in the age of nihilism, when most of the useless drugs of the past had been abandoned and when Osler could find only a dozen or so to recommend for detailed study by his students. Even then, the few great drugs were as well known for their toxic as for their therapeutic effects. Mercury, the recognized specific for syphilis, could cause salivation and loosening of teeth as well as irreparable renal damage. In slight overdosage, digitalis, so helpful in dropsy, was responsible for frequent discomfort and occasional sudden death. The admonition applied during the last half century, when we saw enthusiastic introduction of many therapeutic measures later recognized as unkind, futile, or hazardous. We can shudder now when we remember outdoor treatment of pneumonia, cold tub baths for typhoid, starving of fevers, and withdrawal of water in cholera. We hesitate to think of the harm unwittingly done by the use of aminopyrine, cinchophen, and dinitrophenol. Their wrongful use and many other errors plague our recent past and make us insecure in our present judgments.

Today, when multitudes of new and relatively untried diagnostic and therapeutic procedures form an integral part of the practice of medicine, the admonition "Be sure you do no harm" applies more than ever before. Diagnostic methods formerly simple are becoming increasingly complex and formidable. Sanctioned practice includes use of injections of organic substances for visualization of liver, gallbladder, urinary tract, bronchi, lungs, heart, blood vessels, and spinal canal; air injections for visualization of the brain; cystoscopies, bronchoscopies, esophagoscopies, and gastroscopies; punctures with large needles of bone marrow, liver, and even of lungs, spleen, and kidneys; and catheterization of the great vessels and heart. Therapeutic preparations are confusingly numerous and varied. In the lists of 1953, more than 140,000 medicaments were available to practitioners, and 14,000 new preparations were added during the year. Accretion is still far greater than deletion, although it has been estimated that perhaps 90% of drugs now in common use have been introduced within the last 25 years.[1]

Read before the Section on Internal Medicine at the 104th Annual Meeting of the American Medical Association, Atlantic City, June 8, 1955.

[1] Brown, E. A.: Problems of Drug Allergy, J.A.M.A. 157:814 (March 5) 1955.

Although incalculable benefits have come to mankind with the introduction of these newer diagnostic and therapeutic procedures, hazards of medical management have at the same time enormously increased. Not one of the occasionally indispensable diagnostic tests may be undertaken without risk. The simplest as well as the most complicated possesses inherent danger. Infection may be introduced by a needle; sudden death may follow the intravenous administration of such a relatively inert substance as dehydrocholic acid (Decholin). Furthermore, no agent that can modify the internal environment or organic integrity of the body can be used without hazard. As yet no drug has been found with a single action, and no human body with a single reaction. Risks accompany the use even of those remedies that are regarded as safest. Acetylsalicylic acid is usually given with apparent impunity; yet coryza, bronchospasm, conjunctival injection, eruptions, thrombocytopenic purpura, fever, shock, cardiovascular collapse, and death have followed its use.[2] Although penicillin is correctly regarded as the least toxic of potent chemotherapeutic agents, Welch, Lewis, and Kerlan estimated that from its use 100 to 200 acute anaphylactic-like reactions occur each year.[3]

These accidents, risks, and dangers may be regarded as the price that we, as responsible physicians, must pay for the inestimable benefits of modern diagnosis and therapy. They are the hazards to which, with best intent and most correct practice, we must occasionally subject our patients. In the following discussion about the price we must pay for modern management of disease, care has been taken to exclude from consideration all examples of carelessness, misconduct, malpractice, as well as the use of nostrums, patent medicines, and other unacceptable or condemned remedies. It is believed that all the herein-cited accidents and misfortunes may result on occasion even with enlightened thoughtful use of diagnostic and therapeutic measures by conscientious and well-informed physicians earnestly trying to help their patients. Since even a list of possible dangers would be too cumbersome, examples have been chosen arbitrarily as illustrative of the extent and variety of hazards in our daily work. For orderly presentation, they have been arranged under headings representative both of types of unfavorable responses and of special accidents that may arise in the use of single agents or groups of agents having similar actions.

ACCIDENTAL DRUG INTOXICATION

One of the great hazards in the use of potent drugs is their inherent toxicity that, with wide individual variation, will develop intoxication in any patient if the dose is large enough. An outstanding example is digitalis, in the use of which only a narrow margin separates therapeutic and toxic dosage. In spite of the availability of highly purified crystalline preparations, the dangers of the drug appear to be greater now than ever before. This situation can be attributed to several factors. Among them are dogmatic insistence upon oversimplification of dosage and prevalence of rapid digitalization and intravenous administration. Other factors are related to the use of digitalis in older patients in whom life has been prolonged by other measures and in whom the myocardium is more susceptible to the action of the drug because the failure is more severe. Also implicated is the variable responsiveness to digitalis that results from increasing dependence in cardiac therapy on the manipulation of electrolytes by restriction of sodium in the diet, the stimulation of sodium excretion by mercurial diuretics, and the use of ammonium chloride, cation exchange resins, carbonic anhydrase inhibitors, and cortisone.[4] Whatever may be the factors, the use of digitalis constitutes today one of the most frequent causes of "iatrogenic" disease. Toxic actions are illustrative of the dangers that may be encountered with less well studied and newer drugs. Similar hazards are inherent in the administration of such drugs as scopolamine, curare, and bishydroxycoumarin (Dicumarol), the dangers of which are less important only because these drugs are less frequently used.

MODIFICATION OF INTERNAL ENVIRONMENT

Although the homeostasis of the body is modified by a vast number of drugs in ways but vaguely appreciated, it is most strikingly changed by parenteral injection of fluids of variable composition and by agents that modify the rate of excretion of water, electrolytes, and other substances through kidneys or intestine. Modifications that can be produced by these measures are alarming in variety and degree and only partially predictable. Sodium may be seriously depleted, not only by the sweating that results from hot weather and by restriction of sodium in the diet, but by mercurial and other diuretics.[5] Potentially serious hypopotassemia, with its muscular weakness and cardiac complications, may be promoted by many factors, including acidosis, intravenous injection of glucose and insulin, and the administration of ammonium chloride, commonly used resins, a carbonic anhydrase inhibitor, cortisone, or desoxycorticosterone acetate.[6] Alkalosis and hypochloremia with their baffling nervous and mental symptoms may follow administration of large amounts of alkalis, such as sodium bicarbonate and sodium lactate or may result from gastric suction with removal of excessive amounts of gastric hydrochloric acid.[7] Severe hyperchloremic acidosis with its simulation of cerebral vascular accidents, terminal renal disease, and other forms of acidosis may accompany treatment of heart failure with mercurial diuretics.[8] Acidosis with many troublesome symptoms may follow the administration of ammonium chloride.[9]

These and many other reactions from the use of parenterally given fluids and diuretics are illustrative of the general principle that no modification of homeostasis can be simple and that the manipulation of one factor by drugs or fluids may have unpredictable and subtle effects on another.

INTRODUCTION OF INFECTION

Entry by needles or other instruments into tissues, vessels, or cavities of the body always involves some risk of infection. After cystoscopy bacteremia is not infrequent, and infection of the urinary tract, with or without septicemia, is an occasional complication. It is suspected that the virus of homologous serum jaundice has been introduced by insufficiently sterilized needles in punctures of fingers, ears, or veins. Transfusions may be the source of serious blood stream infections. Recent reports have shown that blood banking, a practice that has saved many lives by making blood readily available, has also introduced new hazards of infection. The possibility of carrying bacteria into the blood during its removal from the donor can not be entirely excluded, and, in rare instances, relatively nonpathogenic bacteria of the Pseudomonas group may accumulate in blood stored at icebox temperature in amounts sufficient to cause fatal intoxication.[10] A much more frequent accident from transfusions is the introduction of the virus of homologous serum jaundice. It is known that a healthy person with no history of hepatitis or jaundice and exhibiting no clinical or laboratory evidence of liver disease may nevertheless carry the virus in his blood. Danger is great from transfusions of whole blood and is much greater from the use of plasma from plasma pools. Since there is at present no known effective method of prevention, hepatitis must be regarded as one of the calculated risks of blood transfusion.[10a]

ALLERGIC REACTIONS

More than 500 separate drugs are known to cause allergic reactions.[1] The unfavorable effects may be expressed by simulation of serum sickness, by the more violent reactions of anaphylaxis, or by affection of one or more of the organs of the body: the skin, bone marrow, lungs, liver, or kidneys. There is great variety and separateness in the response of individual patients to individual drugs. While many drugs cause reactions, there are only a few ways in which the body can react. Thus, the function of bone marrow can be seriously disturbed in an almost identical manner by antibiotic agents, sulfonamides, antihistaminic agents, antimalarials, barbiturates, some heavy metals, amphetamine, urethane, phenylbutazone, glyceryl trinitrate (nitroglycerin), meperidine hydrochloride, and thiouracil.[8] Drugs causing urticaria and other allergic skin reactions are still more numerous. Injury of the liver by action thought to be allergic is encountered with increasing frequency and has been reported after the use of chlorpromazine (Thorazine),[11] pyrazinamide,[12] methyltestosterone,[13] phenylbutazone,[14] and other agents whose toxic or idiosyncratic reactions are as yet only partially evaluated.

SPECIAL INSTANCES OF INTOXICATION

Antibiotics.—Because of the enormous usage of antibiotics, intoxication assumes a prominent role even though it may be statistically infrequent. No antibiotic has as yet been found free from hazards or disadvantages. The side-actions and toxic effects of penicillin have been numerous. In addition to the sometimes fatal anaphylactic responses,[15] there are eruptions of the most diverse type, all manifestations of serum sickness, disturbances of renal function, hypotension, cardiovascular collapse, or unconsciousness; there may be hematological disturbances as various as anemia, agranulocytosis, eosinophilia, and hypothrombinemia.[2]

In their entirety, toxic reactions attributable to antibiotics and chemotherapy are impressive.[16] Anaphylactic reactions have been reported occasionally from most, if not all, of the agents derived from fungi. Hepatic dysfunction has followed the use of streptomycin, chlortetracycline (Aureomycin), oxytetracycline (Terramycin), and chloramphenicol. Renal impairment has been noted after streptomycin therapy and appears as a toxic effect following administration of bacitracin, neomycin, and polymyxin. The incidence of aplastic anemia and other hematological dyscrasias developing during the use of chloramphenicol has been subjected to searching investigation by Welch and associates.[3] Difficulties inherent in attribution of toxic action to any drug appeared in their study. In this instance, as in others, history of exposure did not establish proof of causation of unfavorable symptoms. While circumstantial evidence indicated that administration of chloramphenicol was followed by an increased incidence of bone marrow depression, statistical proof of its action was not established, and it remained questionable whether chloramphenicol is essentially more toxic than some other antibiotics whose record of toxicity has excited less attention. Unfavorable actions of sulfonamides that in some measure have been lost to view because of their replacement by other agents in many therapeutic situations are numerous and include fever, eruptions, blood dyscrasias, and neuritis.

Not the least of the toxic symptoms associated with antibiotics is irritation of the gastrointestinal tract that is particularly severe after the use of tetracycline derivatives. Not infrequently, administration of these drugs has been followed by invasion of the intestinal tract by drug-resistant staphylococci causing infection that may be fatal unless administration of the offending drugs is discontinued and erythromycin therapy instituted.[17] Less serious effects of antibiotics are the development of mycotic infections in the mouth and in the gastrointestinal tract and of vitamin deficiencies attributable to bacteriostatic action on the normal intestinal flora.

Cortisone, Hydrocortisone, and Corticotropin (ACTH).—Unfavorable reactions from the long-term administration of cortisone, hydrocortisone, and corticotropin (ACTH) are well known. In addition to the obesity, hypertension, hirsutism, and osteoporosis of adrenal cortical hyperfunction (Cushing's syndrome), reactions may include increased susceptibility to infection, hindrance of wound healing, or exacerbation of ulcers in the stomach and intestinal tract. A considerable danger results also from rapid withdrawal of the agents after prolonged use.[18]

Antihistaminics.—The antihistaminic agents, of which there are now no less than 20, must be regarded as serious causes of intoxication, more particularly since their use is chiefly among patients who are not seriously ill. Several fatalities have been attributed to them. Their side-effects, especially those observed on the nervous system, are so numerous and sometimes so severe as to suggest that their use is actually more hazardous than that of sulfonamides and antibiotics employed for the most part in treatment of infections that might otherwise result in death.[19]

Phenylbutazone and Chlorpromazine.—Phenylbutazone is a congener of aminopyrine, and its toxic effects, particularly on bone marrow, are reminiscent of the unfortunate experiences with aminopyrine. Side-effects are numerous and sometimes serious; they include edema, eruptions, and unfavorable actions on the gastrointestinal tract, hematopoietic system, central nervous system, and heart.[20] Fatal hepatitis has recently been reported.[14] It is perhaps illustrative of illogical practice that the use of aminopyrine was sharply limited by disclosure of rare instances of intoxication, while the use of a phenylbutazone may now be actually increasing. Current brochures describing clinical uses of chlorpromazine under the name of Thorazine mention its applicability for relief of nausea and vomiting, mental and emotional disturbances, alcoholism, intractable pain, and hiccoughs. Suggestions are included for its use in correction of nausea and vomiting caused by other drugs, such as diethylstilbestrol (Stilbestrol), digitalis, nitrogen mustards, broad-spectrum antibiotics, and general anesthetics. It is thought to be good also for nausea and vomiting in pregnancy. In the psychoses the drug is now being used in large doses at a time when the danger of hidden toxicity, always inherent in new and potent drugs, has been only partially evaluated. Reports of agranulocytosis following its use are in the literature.[22] The incidence of jaundice and disturbed liver function is subject to variable estimates; their nature and seriousness may be judged only by preliminary observations.[11]

HIDDEN AND GENERAL DANGERS

The history of new drugs indicates that not all their potential dangers are immediately apparent. Examples of this are the experiences with cinchophen and aminopyrine. Many years of continued use of each of these drugs elapsed before the unfavorable actions could be established. Still more difficult to evaluate is the inference that past use of drugs may be responsible for the late appearance of symptoms or for development of a chronic disease such as lupus erythematosus or periarteritis. It seems inevitable that with the increasing potency of drugs and the multitude of different reactions caused by single agents that there could be production of syndromes strikingly like those of previously known diseases. Recently, drugs have been introduced for specific purposes that may actually produce complete syndromes.

An outstanding example is the state that develops with some frequency during treatment for hypertension by hydralazine (Apresoline) hydrochloride.[23] In its complete form the syndrome may be manifested by fever; prostration; pleural, pericardial, and joint effusions; skin sensitivity to ultraviolet light; and erythematous eruptions. There may also be lymphadenopathy and splenomegaly. Laboratory studies may show decreased serum albumin and increased alpha and gamma globulin levels, increased sedimentation rate, transient false-positive tests for syphilis, and anemia and leukopenia. Sometimes L. E. cells may be demonstrated in peripheral blood and bone marrow. Histologically abnormal collagen has been seen in muscle and skin. In one case a typical rheumatic nodule was noted, and in another lymphorrhea in muscle resembling that of rheumatoid arthritis was observed. Thus a condition produced by action of a drug closely parallels the clinical, serologic, and histological picture of a serious collagen disease. Only in its reversibility and the relative infrequency of L. E. cells and renal manifestations does it deviate from spontaneously occurring lupus erythematosus disseminatus.

Such a striking simulation of disease as a side-action of a single drug lends some weight to observations that have led to suspicion that adverse action of drugs might be implicated in the pathogenesis of collagen diseases. Evidence of such a relationship has previously been less convincing for lupus erythematosus than for periarteritis nodosa, in which the work of Rich in animals has demonstrated morphological identity of lesions produced by serum sickness and sulfadiazine and the polyarteritic lesions of rheumatic fever and clinical periarteritis nodosa.[24]

DANGERS FROM MULTIPLE PROCEDURES

The danger in diagnostic and therapeutic procedures comes not so much from the use of individual tests or drugs as from the multiplication of these measures now

commonly used in so-called diagnostic surveys and therapeutic regimens in which each symptom receives some remedy. For patients in a diagnostic clinic or in the ward of a modern hospital, the application of 20 or 30 diagnostic tests is not uncommon. Many of these tests may be repeated on several occasions. A seriously ill patient or one who has been subjected to a major operation may receive 20 to 40 different drugs in addition to numerous mechanical procedures. His management may actually require use of anesthetics, sedatives, narcotics, antibiotics in variety, phenylephrine (Neo-Synephrine) hydrochloride, arterenol, digitalis, diuretics, bishydroxycoumarin, cortisone, transfusions, infusions, and finally antihistaminics, either for the correction of symptoms of his disease or to combat the toxic manifestations of other drugs. Since such combinations of measures and medicines are frequent, it is not surprising that iatrogenic disturbances are frequent.

In a medical service in a great hospital, over a period when approximately 1,000 patients were admitted, more than 50 major toxic reactions and accidents consequent to diagnostic or therapeutic measures were encountered. Many of the incidents and accidents took place before the patient's admission to the hospital and provided the occasion for hospitalization. Others developed in the course of diagnosis and treatment in the wards. The survey was not systematic or complete, and some instances of major intoxication may have been omitted from the list. The survey took no account of such factors as inconvenience and expense to the patient, prolongation of hospitalization, minor intoxications, or hidden and delayed reactions.

There were several cases of accidental intoxication, and among these no less than 10 instances of digitalis poisoning. In one of these, ventricular fibrillation and death occurred. Serious hematuria developed in one patient from the use of bishydroxycoumarin; in another there was methemoglobinemia following the use of bismuth subnitrate; one patient was admitted with mental confusion from bromism and another for delirium following therapy with atropine. There was one idiosyncratic response to diphenylhydantoin (Dilantin) sodium and a case of hypotension and vomiting from the use of pentolinium (Ansolysen) tartrate as an antihypertensive agent. There were four examples of reaction to penicillin; one of these was anaphylactic in nature and of such severity that death was averted only by prompt treatment. Two cases of hepatic dysfunction developed during use of pyrazinamide. An acute hemolytic reaction occurred during the use of sulfadiazine. One case of monilial stomatitis and one of severe enterocolitis developed during treatment with tetracycline derivatives.

Three instances of intoxication followed the use of corticotropin and cortisone. One resulted in the formation of multiple gastric ulcers with perforation, hemorrhage, and fatal outcome. Four instances of troublesome acidosis followed use of ammonium chloride. Sensitization reactions were encountered from a number of agents. Eruptions developed from oxytetracycline, pentolinium tartrate, and myleran (1:4-dimethanesulphonyloxybutane); neutropenia from phenylbutazone; agranulocytosis from aminopyrine; and thrombocytopenic purpura from propylthiouracil.

Accidents were not limited to therapeutic procedures. In one instance, a severe blood stream infection following cystoscopy was controlled with difficulty with antibiotics. One young woman, the wife of a physician, died in acute anaphylactic shock 15 minutes after intravenous injection of dehydrocholic acid for determination of circulation rate. Another young woman, a nurse with a congenitally thin sternum, died from cardiac tamponade immediately after a sternal puncture.

In the aggregate, unfortunate sequelae and accidents attributable to sanctioned and well-intentioned diagnosis and therapy were noted in about 5% of patients admitted to medical wards. In this sense, iatrogenic disease could be regarded as one of the commonest conditions encountered during the period.

CONCLUSIONS

It is realized that such concentration on toxic and unfavorable actions of diagnostic and therapeutic measures creates a distorted picture that can be corrected only by detailed recitation of simultaneous benefits. The discussion has been offered without nihilistic intent and with grateful recognition of the triumphs of modern diagnosis and therapy. Choice of topic developed from an ever-growing conviction of the extent and variety of dangers intrinsic in the medical practice of today and from a desire to suggest that discriminating selection of measures may be more important than unreflective completeness. It is suggested that it may be as useful to the patient that his physician know when not to treat as when to treat and that the use of potentially dangerous agents for trivial or inconsequential complaints may not be justifiable. Only by such discipline and understanding may we, as physicians, avoid doing unnecessary harm and minimize the price we and our patients pay for modern management of disease.

CHEMICAL LABORATORY

TESTS AND STANDARDS FOR NONOFFICIAL DRUGS

The following monographs were developed by the Chemical Laboratory for drugs that had been evaluated prior to Jan. 1, 1955, by the Council on Pharmacy and Chemistry. These monographs have not been published previously and are among the last of the Tests and Standards of the monographs that had been prepared during the former "acceptance" program of the Council on Pharmacy and Chemistry.

WALTER WOLMAN, Ph.D., *Director.*

Erythromycin Glucoheptonate.—Erythromycin glucoheptonate is the α-glucoheptonate salt of erythromycin, an antibiotic produced by the growth of Streptomyces erythreus Waksman. The chemical structure of erythromycin glucoheptonate has not been established.

Physical Properties: Erythromycin glucoheptonate is a white, crystalline, odorless powder. It is freely soluble in alcohol and in water, and practically insoluble in ether. The pH of a 2% solution is 6.0-7.5.

Identity Tests: Transfer to a test tube about 10 mg. of erythromycin glucoheptonate and add about 2 ml. of hydrochloric acid: a yellow color appears and changes to dark greenish yellow.

Transfer to a test tube about 5 mg. of erythromycin glucoheptonate and add 5 ml. of sulfuric acid: a red-brown color appears.

Transfer to a separatory funnel about 0.1 gm. of erythromycin glucoheptonate, and add 10 ml. of water, 1 ml. of ammonia T. S., and 10 ml. of chloroform. Shake the mixture and allow it to separate. To the aqueous solution add 10 ml. of alkaline cupric tartrate T. S. and heat to boiling: a yellow-orange precipitate of cuprous oxide forms.

Transfer to a test tube about 50 mg. of erythromycin glucoheptonate and dissolve it in about 5 ml. of water. Add about 5 ml. of a saturated solution of picric acid, allow to stand for about 10 min., and filter. Wash the precipitate with water and dry in a vacuum desiccator: the picrate formed melts at 168-175° (*Caution! Picrates may be explosive*).

A 2% solution of erythromycin glucoheptonate in water is levorotatory.

Purity Tests: On about 0.5 gm. of erythromycin glucoheptonate, accurately weighed, run a *U. S. P. Karl Fischer test for water:* the amount of moisture does not exceed 5.0%.

Char about 0.5 gm. of erythromycin glucoheptonate, accurately weighed, cool the residue, add 1 ml. of sulfuric acid, heat cautiously until evolution of sulfur trioxide ceases, ignite, cool, and weigh: the residue does not exceed 1.0%.

Assay: (Erythromycin) Transfer to a 100 ml. volumetric flask 32.5 mg. of erythromycin glucoheptonate, accurately weighed, fill to the mark with water, and mix. Transfer to a 500 ml. volumetric flask 2 ml. of the solution and fill to the mark with 0.1 M phosphate buffer, pH 8.0, to obtain the assay preparation containing in each milliliter the equivalent of about 1 mcg. of erythromycin as the glucoheptonate. Proceed as directed in the *U. S. P. erythromycin microbial assay.* The amount of erythromycin activity is not less than 85.0% of the theoretical amount.

Dosage Forms of Erythromycin Glucoheptonate

POWDER. *Identity Tests:* The powder responds to the identity tests for the active ingredient in the monograph for erythromycin glucoheptonate.

Assay: (Erythromycin) Transfer the entire contents of the container to a 100 ml. volumetric flask and add sufficient distilled water to make 100 ml. Mix thoroughly and transfer an aliquot portion, equivalent to 25 mg. of erythromycin, to a second 100 ml. volumetric flask, fill to the mark with water, and mix. Transfer to a 500 ml. volumetric flask 2 ml. of the solution and fill to the mark with 0.1 M phosphate buffer, pH 8.0, to obtain the assay preparation containing in each milliliter the equivalent of about 1 mcg. of erythromycin as the glucoheptonate. Proceed as directed in the *U. S. P. erythromycin microbial assay.* The amount of erythromycin activity is not less than 85.0% of the labeled amount.

Eli Lilly & Company cooperated by furnishing scientific data to aid in developing this monograph.

Erythromycin Stearate.—Erythromycin stearate is the stearate salt of erythromycin, an antibiotic produced by the growth of Streptomyces erythreus Waksman. The chemical structure of erythromycin stearate has not been established.

Physical Properties: Erythromycin stearate is a white or slightly off-white, practically odorless, crystalline powder. It is soluble in alcohol and in ether, and is practically insoluble in water. The pH of a 1% slurry is in the range of 6.0-11.0.

Identity Tests: Transfer to a test tube about 10 mg. of erythromycin stearate and add about 2 ml. of hydrochloric acid: a yellow color appears and changes to a dark greenish yellow.

Transfer to a test tube about 5 mg. of erythromycin stearate and add 5 ml. of sulfuric acid: a red-brown color appears.

Transfer to a 50 ml. glass-stoppered Erlenmeyer flask about 0.5 gm. of erythromycin stearate and suspend it in about 10 ml. of water. Add 15 ml. of a saturated solution of picric acid and shake the mixture for 1 hour on a mechanical shaker. Centrifuge the mixture, decant the supernatant solution, and wash the precipitate twice with water, centrifuging the mixture and decanting the supernatant liquid after each wash. Recrystallize the precipitate from diluted alcohol and dry at 105°: the precipitate melts at 168-172° (*Caution! Picrates may be explosive*).

A 2% solution of erythromycin stearate in alcohol is levorotatory.

Purity Tests: Accurately weigh about 0.5 gm. of erythromycin stearate and determine the water content by the *U. S. P. Karl Fischer method:* the amount of moisture does not exceed 5.0%.

Char about 0.5 gm. of erythromycin stearate, accurately weighed, cool the residue, add 1 ml. of sulfuric acid, heat cautiously until the evolution of sulfur trioxide ceases, ignite, cool, and weigh: the residue does not exceed 2.0%.

Assay: (Erythromycin) The erythromycin used in the preparation of erythromycin stearate, assayed by the microbiological method, contains not less than 85% of the theoretical amount.

Dosage Forms of Erythromycin Stearate

SUSPENSION. *Identity Tests:* Transfer to a 125 ml. separatory funnel an amount of suspension equivalent to about 0.5 gm. of erythromycin. Extract with three 25 ml. portions of chloroform, wash the combined chloroform extracts with 10 ml. of water, and evaporate the chloroform layer to dryness. The residue responds to the identity tests for the active ingredient in the monograph for erythromycin stearate.

Assay: (Erythromycin) Transfer to a 100 ml. volumetric flask an amount of suspension, accurately measured, equivalent to about 25 mg. of erythromycin, add 40 ml. of methanol, mix, fill to the mark with water, and mix again. Transfer to a 500 ml. volumetric flask 2 ml. of the solution and fill to the mark with 0.1 M phosphate buffer, pH 8.0, to obtain the assay preparation containing in each milliliter the equivalent of about 1 mcg. of erythromycin. Proceed as directed in the *U. S. P. erythromycin microbial assay.* The amount of erythromycin is not less than 85.0% of the labeled amount.

TABLETS. *Identity Tests:* Powder about 10 tablets. By trituration extract an amount of powder equivalent to about 0.5 gm. of erythromycin with 50 ml. of chloroform and evaporate the filtered chloroform extract on a steam bath. The residue responds to the identity tests for the active ingredient in the monograph for erythromycin stearate.

Assay: (Erythromycin) Transfer to a 100 ml. volumetric flask an amount of powdered tablets, accurately measured, equivalent to about 25 mg. of erythromycin, add 40 ml. of methanol, mix, fill to the mark with water, and mix again. Filter the suspension through a dry filter paper and discard the first 15 ml. of the filtrate. Transfer to a 500 ml. volumetric flask 2 ml. of the subsequent filtrate, fill to the mark with 0.1 M phosphate buffer, pH 8.0, to obtain an assay preparation containing in each milliliter the equivalent of about 1 mcg. of erythromycin. Proceed as directed in the *U. S. P. erythromycin microbial assay.* The amount of erythromycin is not less than 85.0% of the labeled amount.

MODERN ANTIBACTERIAL AGENTS

New antibacterial agents have appeared so fast in the last 20 years that it has been difficult for the average practitioner to keep abreast of developments and to avoid confusion. One of the most troublesome problems is the prophylactic use of such agents. Weinstein [1] has sorted out the indications for such use, the commonest of which is the protection of healthy persons or groups from a specific infection to which they have been exposed or are in danger of being exposed. This has been most successful against beta-hemolytic streptococci and Neisseria gonorrhoeae for which penicillin is best, Neisseria meningitidis for which either penicillin or sulfadiazine is best, and Shigella dysenteriae for which sulfadiazine is best. If the drug of choice is contraindicated or the causative organisms are resistant to it, one of the tetracycline group should be used. Chemoprophylaxis has also been used to prevent secondary infection in a patient acutely ill with a disease for which chemotherapy is not effective, but this has not been generally effective and may even increase the likelihood of complicating bacterial infections with organisms not inhibited by the agent used.

A third common use of chemoprophylaxis is to reduce the risk of infection in patients with chronic disease. This has been most successful in patients with rheumatic fever who appear to be benefited by prolonged treatment with benzathine penicillin. Patients with chronic heart disease may be given prophylactic doses of penicillin for a few days preceding and following the extraction of a tooth. One of the most common uses of chemoprophylaxis is to inhibit the spread of a localized infection in patients who have had accidental or surgical trauma, and it has been commonly used in patients undergoing "clean" operations, especially cataract operations, in which the risk of infection is great. Despite the popularity of this procedure, the results have been negligible in the few controlled series that have been investigated and the risk of superimposed infections is great. In any contemplated use of chemoprophylaxis, it is important to consider only those advantages that are well established and to weigh these against such known dangers as drug allergy, the normal toxicity of the drug to be used, possible disturbances to normal metabolism, and the superimposed infections. Ordinarily use of such agents should not be continued for more than five days.

Hypersensitivity to both sulfonamides and antibiotics has become all too common as a result of widespread exposure. It is estimated that allergy to penicillin is now found in 10% of the population.[2] Deaths from this cause are not uncommon. These drugs are not only used extensively by physicians but also the pharmaceutical companies show an increasing tendency to incorporate them in nose drops, throat sprays, eye drops, troches, chewing gum, and ointments in amounts that are probably ineffective therapeutically but are undoubtedly allergenic.[3] Furthermore, due to the common use of antibiotics in animal husbandry, small amounts are now present in the meat, eggs, milk, and cheese that reach our tables. Because the allergic reaction to these drugs is frequently characterized by fever and rash, it may be difficult to distinguish between the drug reaction and the disease for which it is given. Fortunately in acutely ill patients strong physiological insults may cause the tissues to be unresponsive to allergenic stimuli. An acute infection may cause an increase in adrenocortical activity, thereby suppressing an allergic reaction. If, however, a fever persists when the patient's general condition has improved and the physical signs of his disease have cleared, this is not an indication for increasing the dose of a chemotherapeutic agent but rather a reason to discontinue its use.

There is some disagreement as to whether a physician should ever prescribe a specific drug without laboratory identification of the causative organism. Selection of the best drug to use often depends not only on such an identification but also on tests of the sensitivity of the organism to the drug. The clinician's dilemma is that, if his treatment is to have its greatest effect, it must be given early in the course of the disease, and if he waits for laboratory tests he may lose much valuable time and incur the wrath of the patient or the patient's family. McDermott [4] believes that the only solution at present is for the physician to make a tentative diagnosis based on a careful evaluation of his clinical findings, take speci-

mens for culture before starting treatment, select the drug most likely to benefit the patient if his tentative diagnosis is correct, and give this drug in adequate doses. If laboratory results indicate that his diagnosis was in error, he can change the medication and be no worse off than if he had waited with his hands folded for the laboratory report. McDermott also believes that the results of disk plate sensitivity tests are so often unreliable as to be of doubtful value.

Lepper,[5] in a detailed study of microbial resistance to antibiotics, suggests methods of minimizing the development of such resistance: chemotherapeutic agents may be used in combination; new drugs can be introduced; antibiotics of limited scope should be used and only in minimal effective doses. These and other measures will aid in maintaining the usefulness of many of our most powerful therapeutic agents. With the troublesome problems of hypersensitivity, drug resistance, and superimposed infections, interest in the sulfonamides is being revived.[2] In the period following the introduction of penicillin, new and safer sulfonamides have been synthesized. Most of the serious complications such as hematological disorders were reduced to less than 0.1% by the use of sulfadiazine. More recently sulfisoxazole, which is 10 times as soluble as sulfadiazine, has been introduced. Fortunately, combining sulfonamides produces an additive bacteriostatic effect, but the drugs combined have their independent solubilities in the urinary tract. This reduces the danger of renal tubular irritation and blockage. Because sulfonamides produce less drastic changes in the normal flora of the body than do the antibiotics, their use is attended by less risk of superimposed infections. In many diseases sulfonamides are as effective as antibiotics. In some diseases the combination of an antibiotic and a sulfonamide produces the best results. From these observations it should be abundantly clear that in medicine nothing is static. Research investigators continue to provide us with better means of combatting disease, but the clinician must still bring judgment and skill to bear to obtain the best results and above all to keep these new drugs from falling into disrepute.

E. Roger Samuel, M.D.

THE GENERAL PRACTITIONER'S AWARD

Dr. E. Roger Samuel of Mount Carmel, Pa., was named the General Practitioner of the Year at the opening session of the House of Delegates of the American Medical Association November 29 during the Ninth Clinical Meeting in Boston. A general practitioner for 35 years, the 66-year-old physician was nominated by the Medical Society of the State of Pennsylvania, after original sponsorship by the Northumberland County Medical Society and the Mount Carmel Rotary Club. His nomination carried with it testimonials from patients, colleagues, fraternal and civic groups, and churches.

Dr. Samuel, who practices medicine in the Pennsylvania town where he was born, was chosen for the honor by an unidentified A. M. A. committee from candidates nominated by each of the state medical societies, which in turn received nominations from county medical societies. He has continuously devoted time and effort to public service and has served diligently and enthusiastically in civic and religious groups covering a wide range of interests. A 33rd degree Mason, he has been trustee, treasurer, and Sunday school teacher of the First Methodist Church, president of the Community Concert Association, president of the Northumberland County unit of the American Cancer Society, medical advisor of the tuberculosis and health committee, and member of the board of the Mount Carmel Red Cross chapter and the Mount Carmel Rotary Club. He has served as chairman of the School Boy Patrol of the Mount Carmel Motor Club since it was formed.

Dr. Samuel attended Dickinson College and was graduated from the University of Pennsylvania School of Medicine; then, after a year as pathologist at the Pennsylvania Hospital in Philadelphia, he entered general practice in Mount Carmel. During World War I he served as captain in the Army Medical Corps assigned to the British Expeditionary Forces and was awarded the Purple Heart. He is a charter member and past-commander of the Mount Carmel American Legion post. A member of the Selective Service Board during World War II, he was active in civil defense, establishing first-aid stations throughout the area. He has been president of the Board of Health, Fraternity Club, Kiwanis Club, and president and founder of the Mount Carmel Chamber of Commerce.

Dr. Samuel has been president of his county and state medical societies and formerly was a member of the House of Delegates of the American Medical Association. He also has been president of the staff at the Shamokin State Hospital, compensation doctor for the Jeddo-Highland Coal Company, surgeon for the Lehigh Valley Railroad Company, member of the board of the Medical Service Association of Pennsylvania (Blue Shield), and a member of the American Academy of General Practice, the World Medical Association, and the Association of Railway Surgeons.

MEDICINE AND THE LAW

GROUP MEDICAL AND HOSPITAL SERVICE PLAN: NO VIOLATIONS FOUND

The Supreme Court of California in July, 1954, handed down its decision in *Complete Service Bureau* v. *San Diego County Medical Society*.[1] This case was concerned with the legality of certain aspects of the organization and operation of a "prepaid" group medical and hospital service plan, the Complete Service Bureau (CSB). The San Diego County Medical Society and some 30 of its member physicians had brought action against CSB seeking to enjoin it from certain allegedly unlawful practices in the carrying on of its business. It was alleged that (1) CSB had failed to comply with section 9201 of the California Corporations Code; (2) CSB was engaged in the corporate and lay practice of medicine; (3) the physicians connected with CSB were aiding and abetting the lay practice of medicine; (4) CSB and the physicians connected with it were splitting fees; (5) CSB engaged in intensive solicitation of patients; (6) much of CSB's advertising was misleading; (7) the practices of CSB and the physicians connected with it amounted to unfair competition with respect to the members of the San Diego County Medical Society; and (8) the commercialization of the practice of medicine which is harmful to the public health and welfare, was inherent in the activities of CSB. There was no allegation that the medical services furnished by CSB were in any way inadequate.

The facts as to CSB's formation and operations were not disputed. In 1939, one Parmer and two associates, none of whom was licensed to practice medicine, organized CSB under section 9200 of the California Corporations Code. Section 9200 provides: "A nonprofit corporation may be formed . . . for any lawful purposes which do not contemplate the distribution of gains, profits or dividends to the members thereof and for which individuals lawfully may associate themselves, such as . . . rendering services, subject to laws and regulations applicable to particular classes of nonprofit corporations or lines of activity. . . ." The articles of incorporation provided that CSB's main purposes were the establishment and maintenance of a fund obtained through periodic payments by its members, which fund was to be used to defray the cost of medical services and hospital care to members; to supply or procure at the lowest cost medical, hospital, and other services to the members on a periodic payment plan; and to furnish medical and hospital service to its members without profit to any agency.

Parmer was hired as manager of CSB under a 20 year contract. The rights under this contract were specifically made assignable and inheritable. Parmer was not required to devote all of his time to the job and could engage in any other occupation he chose. The contract provided that Parmer's compensation was to be 10% of the monthly dues paid by the members of CSB. Parmer's average annual income under this contract has been $8,320. Further, he was given under the contract an option to purchase at any time any or all of the real or personal property owned by CSB at its original cost, less depreciation. CSB leased a building in which medical services were to be furnished; under the lease CSB was given an option to purchase. A group of doctors were employed to perform the medical services at the leased building. The doctors were paid approximately 50% of the fees collected by CSB in accordance with a unit system.

At the time of the trial CSB had approximately 10,000 subscribers who paid $2.50 a month. This payment entitled a subscriber to up to 30 days' hospitalization for each sickness or injury, up to $10 toward ambulance service for each sickness or injury, and medical services in accordance with a schedule of fees listed. The subscribers' voting rights were restricted, and no subscriber had ever attended a meeting of CSB. Only once, immediately prior to the trial, had the subscribers been given effective notice of a meeting of CSB.

In 1940, CSB exercised its option and purchased the leased building at a price of $31,000. Parmer and the head doctor of CSB formed Group Property (GP), a stock corporation, in 1946. At that time Parmer exercised his option to purchase CSB's real property at the price of $31,000; the purchase price was paid in GP stock. Parmer then sold the building to GP for $102,500, payable in GP stock. Then Parmer, in his capacity as president of GP, leased the building to himself in his capacity as president of CSB on a month-to-month basis for a rent of 10% of the gross income of CSB. During the two and one-half years preceding the trial, GP received $108,000 from CSB in the form of rent. GP has paid no salaries and declared no dividends; it has spent approximately $100,000 in remodeling and refurnishing the building that it rents to CSB.

The trial court found for CSB on all issues. It took the position that section 9201 of the California Corporations Code provided an alternative, but not mandatory, method of organizing a nonprofit corporation for the purpose of rendering personal service and did not repeal or affect section 9200 of the California Corporations Code in any way. The trial court's conclusion that the specific activities of CSB that were complained of were not unlawful was apparently based on a finding that similar activities were engaged in by the California Physicians Service (CPS), an organization sponsored by the California Medical Association and its constituent county societies.

The district court of appeals for the fourth district reversed the judgment of the trial court.[2] The district court regarded section 9201 as a law applicable to CSB's particular line of activity with which under the terms of section 9200 CSB was required to comply, rather than as an alternative method of organizing a nonprofit corporation for the purpose of rendering personal service. The district court further said that CSB's advertising was illegal and misleading and that there was splitting of fees in actuality if not in form.

---

[1] 272 P. (2d) 497 (Calif., 1954).

[2] 260 P. (2d) 1038 (Calif., 1953).

The Supreme Court of California affirmed the judgment of the trial court on all issues. The medical society contended that a nonprofit medical service corporation could now be organized only under section 9201. Section 9201, which was enacted in 1941, provides that "A nonprofit corporation may be formed under this part for the purposes of defraying or assuming the cost of professional services of licentiates under any chapter of Division 2 of the Business and Professions Code or of rendering any such services, but it may not engage directly or indirectly in the performance of the corporate purposes or objects unless all of the following requirements are met: (1) at least one-fourth of all licentiates of the particular profession become members; (2) membership in the corporation and an opportunity to render professional services upon a uniform basis are available to all licensed members of the particular profession; (3) voting by proxy and cumulative voting are prohibited; (4) a certificate is issued to the corporation by the particular professional board whose licentiates have become members, finding compliance with the requirements of subdivisions (1), (2), and (3). Any such nonprofit corporation shall be subject to supervision by the professional board under which its members are licensed and shall also be subject to Section 9505." The Court held that a nonprofit medical service corporation could be formed under either section 9200 or section 9201. It was pointed out that section 9201 did not purport to repeal any part of section 9200 and that the language of section 9201 was permissive rather than mandatory. (In connection with this point, the Court cited *Group Health Association* v. *Moor*.[3] That case has no bearing on the point. The Moor case was concerned with the question of whether the formation of a corporation by a group of individuals, the purpose of which was to contract with groups of doctors for medical services, would constitute the practice of medicine. There was no question in the case of the proper interpretation of any statute providing for the incorporation of a nonprofit medical service corporation.) The Court rejected as dictum the statement in *Maloney* v. *American Independent Medical and Health Association*[4] that corporations such as CSB are also subject to the provisions of section 9201. The Court said that to regard all nonprofit medical service corporations as subject to section 9201 might lead to serious legal difficulties. There are a number of fraternal and beneficial organizations, formed under section 9200 prior to the enactment of section 9201, that have entered into contracts with subscribers and other persons to carry out their purpose of furnishing medical services. (In discussing this point the Court made no mention of *People ex rel. State Board of Medical Examiners* v. *Pacific Health Corporation, Inc.*,[5] wherein it is said, with respect to medical service plans run by fraternal and labor organizations, "But a most obvious and, to us, a fundamental distinction must be made between defendant and these other institutions. In nearly all of them, the medical service is rendered to a limited group as a result of cooperative association through membership in the fraternal or other association, or as a result of employment by some corporation which has an interest in the health of its employees. The public is not solicited to purchase the medical services of a panel of doctors; and the doctors are not employed or used to make profits for stockholders. In almost every case the institution is organized as a nonprofit corporation or association. Such activities are not comparable to those of private corporations operated for profit and, since the principal evils attendant upon corporate practice of medicine spring from the conflict between the professional standards and obligations of the doctors and the profit motive of the corporation employer, it may well be concluded that the objections of policy do not apply to nonprofit institutions.")

If the legislature had intended by enactment of section 9201 to eliminate these preexisting corporations, there would be a question of the impairment of contracts. The Court said that it was unlikely that the legislature was considering fraternal and other mutual nonprofit corporations when it enacted section 9201. In support of this conclusion the Court pointed out that it would be unreasonable to require such groups to include one-fourth of all licentiates as members or to require such limited groups to provide all licensed members of the profession an opportunity to render professional services. The Court further said that if section 9201 should be held to be the only section under which a nonprofit medical service corporation could be formed, there is the possibility that CPS, which is sponsored by the California Medical Association and all of its county medical societies, might exercise a monopoly in the field.

The medical society further contended that, even if a medical service corporation can be formed under section 9200, CSB was engaged in certain activities that were violative of chapter 5 of the California Business and Professions Code and that should therefore be enjoined. It was alleged that CSB was engaged in the corporate practice of medicine. Doctors presently employed by CSB and doctors who had been employed by it in the past testified that at no time had there been any interference with their practice of medicine. The Court regarded this testimony as substantial evidence to support the trial court's finding that only licensed physicians employed by CSB were engaged in the practice of medicine.

It was next alleged that CSB and members of its medical staff were engaged in splitting fees. This allegation was based on: (1) Parmer's contract as manager of CSB; (2) the rental lease between CSB and GP; (3) the fact that the doctors employed by CSB are compensated under the unit system; and (4) the fact that the doctors receive only 50% of the amounts collected by CSB. An expert witness testified that the salary range for a lay manager of a clinic such as that operated by CSB was $6,000-$15,000 per year. Parmer's average annual income, $8,320, was well within that range. In connection with the rental lease the Court pointed out that GP had paid no salaries, had neither declared nor paid any dividends, and that it had spent $100,000 in remodeling and refurnishing the building. It was stated that the unit system was a customary method of payment to members of medical groups. The other 50% of the amounts collected by CSB is used to pay overhead expenses. There was testimony that 50% was a "standard" figure for overhead expenses for medical practice in general and also for group practice. The Court said that these factors constituted substantial evidence to support the trial court's conclusion that there had been no splitting of fees. Judge Edmonds, in a dissenting opinion, questioned the soundness of the majority's conclusion with respect to some of these factors. He stated that, in view of the vague nature of Parmer's duties under his management contract, there is considerable doubt that the amounts paid to him can be regarded as compensation for services actually rendered. He further pointed out that it was immaterial that GP had paid no dividends, because its net worth had increased and Parmer, as controlling stockholder, could declare a dividend at any time he wished. Judge Edmonds concluded by saying, "In any event, it is a novel proposition of law that one who receives funds from an improper source, or gains them in an improper manner, may be excused from legal consequences if he does not take too much."

---

[3] 24 F. Supp. 445 (Washington, D. C., 1938).

[4] 259 (2d) 503 (Calif., 1953).

[5] 82 P. (2d) 429 (Calif., 1938).

The Court found that there was substantial evidence to support the trial court's conclusion that none of CSB's advertising was, as the medical society had alleged it to be, false or misleading. The medical society had complained of those advertisements of CSB in which it had referred to its plan as a prepaid medical plan and to its advertisements that said, "Surprise! A 24-Hour Medical-Surgical Hospital Service for Only $2.50 a Month" and "You will be surprised how much medical, surgical and hospital care you can buy for $2.50 a month." The Court said that these advertisements were not misleading because all of CSB's members were advised of the medical fee schedule that was part of their contract and that none of them thought they were going to receive complete medical, surgical, and hospital care by prepaying $2.50 a month. The medical society had also complained of an advertisement, which read, "Your money goes for Medical Care and other Hospital Services exclusively," on the ground that it was false and misleading, since Parmer received a part of the money for his services as manager. The Court said that this would probably have made no difference to the subscribers. In connection with the question of whether the advertisements of CSB were false and misleading, advertisements of CPS were introduced in evidence to show the similarity between the two. The Court took the position that, although common practice is generally reasonable and lawful practice, it is not always so. It regarded the type of advertising used by CPS as merely one factor to be used in determining the legality of CSB's advertising, rather than assigning a conclusive weight to this factor as was apparently done by the trial court.

It was also held by the Court that CSB's advertising did not, as had been alleged by the medical society, violate section 2380.5 of the Business and Professions Code, which provides that "All advertising of the medical business in connection with which the holder of any certificate fails to use his name constitutes unprofessional conduct within the meaning of this section." It was said that this section was not applicable to nonprofit medical groups because they do not hold medical licenses and are not advertising in behalf of any particular doctors. To support this conclusion that the advertising was not in behalf of any particular group of doctors, the Court pointed out that the relation between the physicians and CSB could be terminated on 60 days' notice.

The medical society had alleged that CSB's solicitation of members through hired solicitors violated section 2399 of the Business and Professions Code, which forbids the employment of "cappers" or "steerers" in the procuring of practice for a medical practitioner. The Court said that medical service groups, including CPS, commonly solicit members and that these activities were not intended to be within the scope of the statute. The fact that CSB's staff of doctors is not constant indicates that the members are being solicited for the group rather than for any particular practitioner.

The Court said that there was no evidence in the record to support the medical society's allegation that the activities of CSB constituted unfair competition.

It was said in conclusion that there was sufficient evidence in the record to support the trial court's general conclusion that none of the activities or policies of CSB was harmful or inimical to the public health and welfare and that none of them would lower the standards of the medical profession.

It is difficult to say just what is the significance, with respect to the law relating to corporate practice of medicine, group medical and hospital service plans, and splitting of fees, of the decision in the *Complete Service Bureau* case. The decision can be regarded as nothing more than a statement that there was sufficient evidence to support the trial court's conclusion that no part of CSB's organization or operations was in violation of the existing law; the decision, therefore, made no new law. However, the Supreme Court, in its opinion, cited only a few previous cases, none of which seem particularly applicable to the matter that was before it. The Court did cite *Pacific Employers Insurance Company* v. *Carpenter* [6] in support of the proposition that the professions are not open to commercial exploitation and that it is against public policy to permit a middleman to intervene for profit in establishing the professional relationships between the members of a profession and the members of the public; but, the Court went on to say that ". . . this principle is not contravened by permitting a group of interested persons to form a nonprofit corporation to secure for themselves medical services at a low cost." It might be that the Supreme Court of California regarded any evils of the commercialization of the medical profession that might arise from CSB's methods of operations as being outweighed by the good that it felt resulted from CSB's furnishing of admittedly adequate medical services at a low cost to a large group of persons, who might not otherwise be able to obtain such services.

---

6. 52 P (2d) 992 (Calif., 1935).

MEDICAL NEWS

CALIFORNIA

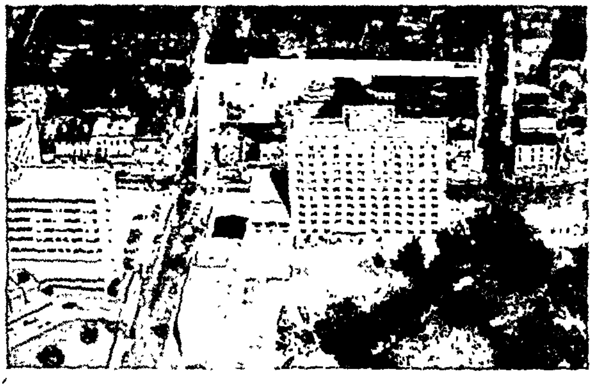
Student Loan Fund.—The Loma Linda Foundation fund of the College of Medical Evangelists recently received $100,000 from a patient at Glendale Sanitarium and Hospital, whose father was a physician. The gift, made in the form of an annuity in appreciation and recognition of the medical care received from hospital personnel, will eventually become available for student loans, which now total about $500,000, including loan funds handled in trust.

Emotional Problems in Office Practice.—The University of California Extension offers a class in treatment of those with emotional problems in office practice on Thursdays, 8-10 p. m., Jan. 5-March 22, 1956, in room 108, Old Religious Conference Building on the Los Angeles campus, with Dr. Frank F. Tallman, professor of psychiatry, as instructor. Enrollment is limited to 25 persons. Application and fee ($50) should be mailed promptly to Dr. Thomas H. Sternberg, Assistant Dean for Postgraduate Medical Education, University of California Medical Center, Los Angeles 24.

Physicians' Art Show.—Coincident with the midwinter medical meeting of the Los Angeles County Medical Association, the Los Angeles Physicians' Art Society will stage its annual exhibition from Dec. 20, 1955, to Jan. 20, 1956, at L. A. C. M. A. headquarters, 1925 Wilshire Blvd. Physician-artists (duly paid members) should send their most recent works (limit three) to the L. A. C. M. A. Auditorium, to arrive not later than 5 p. m., Dec. 16. There will be a hanging charge of $2 each for two pieces submitted; three pieces, $5. Names and media of pieces submitted must be in the hands of Miss Virginia Brown, executive secretary of the society, 1234 N. Vermont Ave., Los Angeles 29, by Dec. 12. A cocktail party and dinner ($3.50) at 6:30 p. m., Dec. 20, will open the exhibition.

CONNECTICUT

Harkness Residential Hall at Yale.—The Edward S. Harkness Memorial Hall, a residential center for medical students, was dedicated Oct. 7 at Yale University in New Haven. Dr. Vernon W. Lippard, dean, Yale University School of Medicine, was presiding officer for the program. The structure, which covers a block in the heart of the Yale-New Haven Medical Center, is named after the late Edward S. Harkness, whose gifts to Yale for new buildings are said to have changed the face of the campus in the 1920's and 1930's. The red-brick building has two wings—one 11 stories high and the other 4 stories, connected by a 2-story structure housing a lounge and a dining hall. The dormitory space includes accommodations for 266 medical students, both men and women; special apartments for married students; a special apartment for the resident faculty member, Dr. Donald P. Shedd, assistant professor of surgery; and a guest suite for visiting lecturers and scientists. Residential facilities include dining rooms, gymnasium, a game and music room, and snack bar.



The L-shaped Edward S. Harkness residential hall occupies a triangular block. The Grace-New Haven Community Hospital is located at the left, across the street.

Yale Appointments in Anesthesiology.—Dr. Nicholas M. Greene, previously associate professor of anesthesia at the University of Rochester School of Medicine and Dentistry and anesthetist-in-chief of Strong Memorial Hospital in Rochester, N. Y., joined the faculty of Yale University School of Medicine, New Haven, July 1, as professor of anesthesiology and lecturer in pharmacology. Dr. Greene will be director of anesthesiology in the Grace-New Haven Community Hospital. He will develop an expanded teaching and investigative program in anesthesiology at Yale, assisted by Dr. Alastair J. Gillies, formerly of Rochester, N. Y., who has been appointed assistant professor of anesthesiology and associate director of anesthesia at the Grace-New Haven Community Hospital. Dr. Gillies' father is professor of anesthesia at Edinburgh University, Scotland.

ILLINOIS

Personal.—Dr. Richard J. Graff, superintendent of Manteno State Hospital, recently received a citizen's award commemorating his 25 years as a physician dedicated to care of the mentally ill. A silver plaque was presented to him during the third annual volunteer award ceremonies at Manteno.

Symposium on Arteriosclerosis.—In cooperation with the Chicago Heart Association, the Aux Plaines branch of the Chicago Medical Society will present a symposium on arteriosclerosis Dec. 16 at the Oak Park Club (Euclid 6-8200), 721 Ontario, Oak Park. Dinner, 7 p. m., will be preceded by a fellowship hour. "Pathogenesis—Epidemiological Evidence" will be considered by Dr. Jeremiah Stamler, Chicago, and "Pathogenesis—Experimental Evidence" by Dr. Ruth Pick, respectively assistant director and research associate, cardiovascular department, Medical Research Institute, Michael Reese Hospital, Chicago. Clinical aspects will be discussed by Dr. Norman B. Roberg, associate professor of medicine, University of Illinois College of Medicine, Chicago. Audience participation will follow. All physicians are welcome.

Chicago

Society News.—The Society of Medical History of Chicago will hold an open meeting at the Institute of Medicine (fourth floor, 86 E. Randolph St.) Dec. 14, 8 p. m. Dr. Lester S. King will present "Similia Similibus" and Dr. Israel Davidsohn, "Medical Caricatures—A Mirror of Medical History." All are welcome.

CIO Health Center.—The Sidney Hillman Health Center, the nation's fourth health center to provide medical care for CIO unionists in the clothing industry was recently dedicated by the CIO Amalgamated Clothing Workers of America. It occupies two floors of the Amalgamated center at 333 S. Ashland Ave. Its staff, headed by Dr. William S. Hoffman, professorial lecturer in medicine at the University of Illinois College of Medicine, will include 30 specialists and a staff of technicians.

The Physician in Dental Diagnosis.—As part of its postgraduate course in diagnosis, roentgenography, and treatment planning, the Northwestern University Dental School will present a lecture, "The Role of the Physician in Diagnosis in Dentistry," by Joseph C. Calandra, Ph.D., professor of pathology, Dec. 14, 9 a. m. "Clinical and Roentgenographic Correlation Between Oral and Systemic Diseases" will be considered by Arthur Elfenbaum, D.D.S., chairman of the department of diagnosis.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

WTTW to Rerun "March of Medicine."—In conjunction with the beginning of its full-time operation, station WTTW will rerun on channel 11 the series of medical documentaries, the March of Medicine, originally produced by Smith, Kline & French Laboratories in cooperation with the American Medical Association. The 10 week series, sponsored by the Chicago Medical Society, will be presented each Wednesday night at 9 p. m., as a public service feature. The first telecast, Dec. 14, will be "We, the Mentally Ill," narrated and enacted by mental patients.

IOWA

Health Forums.—The Scott County Medical Society in conjunction with the Davenport Newspapers, Inc., held a public forum on poliomyelitis Nov. 3 and one on "The Wonder Drugs" Nov. 10 in Davenport. This is the third year that the free public forums have been held.

University News.—Dr. Robert C. Hickey, associate professor of surgery, State University of Iowa College of Medicine, Iowa City, has been named assistant dean for research. He will be responsible for the coordination and administration of more than 200 teaching and research grants and research fellowships. His duties as assistant dean will be in addition to his teaching.——Dr. Iain Maclean Smith, formerly affiliated with the department of pathology and microbiology, Rockefeller Institute for Medical Research, New York, has been appointed assistant professor of internal medicine at the University Hospitals, State University of Iowa, Iowa City. Dr. Smith, a graduate of the University of Glasgow, Scotland, has served at Barnes Hospital, St. Louis, Johns Hopkins Hospital, Baltimore, and Sheffield University, Sheffield, England. Members of the department who have recently been promoted include Dr. James W. Culbertson, from associate professor to professor, and Dr. Bernard I. Lewis, from assistant professor to associate professor.

KENTUCKY

Rural Health Conference.—The 1956 Kentucky State Rural Health Conference will be held at the Kentucky Hotel, Louisville, Jan. 19, 1956, under the sponsorship of the Kentucky Rural Health Council and the Kentucky State Medical Association.

Students Honor Dr. Ackerly.—A group of psychiatry students has honored Dr. S. Spafford Ackerly, Louisville, by establishing the "Ackerly Society of Psychiatric Residents of the University of Louisville School of Medicine." The society gave a dinner on July 12 for Dr. Ackerly, who is chairman of the department of psychiatry at the medical school.

MARYLAND

Appoint Professor of Urology.—The University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, announces the appointment of Dr. John D. Young Jr. as professor of urological surgery to fill the vacancy created by the retirement of Dr. W. Houston Toulson. Dr. Young obtained his medical degree from the University of Maryland in 1941. During World War II he served in the U. S. Army, from which he was discharged with the rank of captain in the medical corps. He has been on the staffs of University Hospital and the Johns Hopkins Hospital, Baltimore.

Award to Dr. Pincoffs.—Dr. Maurice C. Pincoffs, head, department of preventive medicine, University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, has received the Alfred Stengel Memorial award from the American College of Physicians. To attain this honor, the candidate "must have displayed an outstanding influence in maintaining and advancing the best standards of medical practice and clinical research in perpetuating the history and traditions of medicine and medical ethics in upholding the dignity and efficiency of internal medicine in its relation to public welfare." Dr. Pincoffs, currently editor of the *Annals of Internal Medicine*, is a past-president of the American College of Physicians.

MICHIGAN

Program on Chronic Disease.—As part of a two day in-service training program on chronic disease for the staff of the Michigan Department of Health and local full-time health officers, the division of tuberculosis and adult health, Michigan Department of Health, will sponsor a dinner meeting at the Hotel Porter, Lansing, Dec. 19, 6:30 p. m. The speaker will be Dr. Cecil G. Sheps, executive director, Beth Israel Hospital, Boston.

NEBRASKA

Director of Psychiatric Research.—Dr. Jackson A. Smith, formerly assistant professor of psychiatry at Harvard Medical School, Boston, and Baylor University College of Medicine, Houston, Texas, has joined the staff of the Nebraska Psychiatric Institute as director of research and will also serve as professor of neurology and psychiatry at the University of Nebraska College of Medicine, Omaha. Dr. Smith will develop and direct a statewide psychiatric research program for which the state legislature has appropriated funds. Research now under way includes the study of geriatric problems and problems of emotionally disturbed children.

NEW YORK

Einstein College Professorial Appointments.—The Albert Einstein College of Medicine of Yeshiva University has announced appointment of the following physicians as professor and chairman of their respective departments: Ernst A. Scharrer (anatomy), Irving London (medicine), Alfred Angrist (pathology), Henry L. Barnett (pediatrics), Henry D. Lauson (physiology), Marcus D. Kogel, dean (preventive and environmental medicine), Milton Rosenbaum (psychiatry), Milton Elkin (radiology), and Leo M. Davidoff (surgery). Drs. John Frosch and Charles B. Ripstein have been appointed professor and executive officer of the departments of psychiatry and surgery, respectively, and Dr. Henry B. Makover, professor of preventive and environmental medicine.

Personal.—Dr. Samuel K. Levy, Brooklyn, has been appointed chief attending pediatrician at the Bushwick Hospital, Brooklyn. He is associate attending pediatrician at the Maimonides Hospital.——Dr. Leo M. Taran has resigned as medical and research director at St. Francis Sanatorium for Cardiac Children, Roslyn, with which he has been affiliated since its founding in February, 1938. Dr. Taran's offices are now located at the Garden City Medical Center, 520 Franklin Ave., Garden City.——Dr. Robert C. Hunt, assistant commissioner for community mental health services, New York State Department of Mental Hygiene, recently conducted a six weeks' study of community mental health activities in Holland and England under a fellowship from the United Nations World Health Organization.

Mental Clinic.—The third of four centralized clinics designed to provide after-care for mental patients in the New York City area has been opened at 150 Hillside Ave., Jamaica, Long Island. The other new clinics are at 105 Schermerhorn St., Brooklyn, and 1910 Arthur Ave., Bronx. An existing clinic in Manhattan is to be expanded and converted to the new system at a later date. Dr. Eugene B. F. Riley, formerly supervising psychiatrist at Creedmoor State Hospital, Queens Village, is psychiatrist in charge at the Queens clinic. The services are available presently only to patients released from Creedmoor State Hospital since Sept. 1, 1955. The program will be expanded as professional workers are available and will later provide treatment services for all persons residing in Queens County who have had psychiatric treatment in the department's institutions. The new after-care clinics replace those formerly conducted by individual state institutions.

Society News.—At the last meeting of the Kings County Radiological Society, Dr. Louis Goldfarb was elected president; Dr. Hyman I. Teperson, vice-president; Dr. Solomon Maranov, secretary; and Dr. Ernest I. Melton, treasurer, all from Brooklyn.——At its meeting Dec. 20 in MacNaughton Auditorium, the Medical Society of the County of Kings will present "The Management of Advanced and Recurrent Carcinoma" by Dr. J. Englebert Dunphy, professor of surgery, Harvard Medical

School, Boston.——The Brooklyn Urological Society will have as speaker (Dec. 13, 9 p. m., in the Kings County Medical Society Building, 1313 Bedford Ave.) Dr. Wyland F. Leadbetter, chief of urology, Massachusetts General Hospital, Boston, whose topic will be "Cystectomy and Urinary Diversion."——Newly elected officers of the Nassau Radiological Society (19 Clinton Rd., Garden City) include: Dr. Herbert R. Zatzkin, Hempstead, president; Dr. Arthur I. Frucht, Hempstead, vice-president; Dr. Frances M. Behrendt, Garden City, secretary; and Dr. John Knapp, Freeport, treasurer.

New York City

Harvey Lecture.—Dr. Karl Meyer, professor of biochemistry, Columbia University College of Physicians and Surgeons, will deliver the fourth Harvey Lecture of the 1955-1956 series at the New York Academy of Medicine Dec. 15 on "The Chemistry of the Mesodermal Ground Substances."

Dr. Bugher Receives Award.—Dr. John C. Bugher, who retired Sept. 30 as director of the division of biology and medicine of the U. S. Atomic Energy Commission, was presented the Atomic Energy Commission Distinguished Service award and the Superior Accomplishment award, the latter carrying a cash award of $2,000. Dr. Bugher has returned to the Rockefeller Foundation, where he is now director of medical education and public health.

Courses on Cardiology.—Dr. Arthur M. Master will conduct a course in elementary electrocardiography, PM 41, Jan. 16-21, 1956, and a course in advanced electrocardiography, PM 42, Jan. 23-28, at Mt. Sinai Hospital. Morning sessions will be held Monday through Saturday from 10 a. m. to 1 p. m.; Monday, Wednesday, and Friday afternoon classes will meet from 2 to 4 p. m.; Tuesday and Thursday afternoon classes from 2 to 5 p. m. Dr. Master will conduct a course on cardiovascular diseases, PM 31, Jan. 30 to Feb. 10, Monday through Friday, 9 a. m. to 12 noon and 1 to 5 p. m.

Health Department Needs Part-Time Pediatricians.—The children's services in the department of health have a few vacancies for part-time physicians with training in pediatrics. Arrangements are generally made for service for five morning sessions a week. Physicians are paid on a per session basis. Before employment, a short orientation and training course is given. Interested physicians are requested to call the health department at WOrth 2-6900 (for work in child health stations, ask for the Bureau of Child Health, Extension 461; for work with school age children, Bureau of School Health, Extension 320; and for work with the Bureau for Handicapped Children, Extension 229).

Dr. McCormack Accepts Hospital Post.—Dr. James E. McCormack, associate dean for graduate studies, Columbia-Presbyterian Medical Center, has been appointed an assistant vice-president of the Presbyterian Hospital, where he will be responsible for public interest and for professional services. A consultant to the Assistant Secretary of Defense and a member of the Civilian Health and Medical Advisory Council, Dr. McCormack was previously associated with the Office of Scientific Research and Development and with the Research and Development Board of the Department of Defense and since 1950 has been executive director of the New York City Medical Advisory Committee to the Selective Service system. He is also chairman of the New York committee on the study of hospital internships and residencies.

Grants in Accident Prevention.—Two two-year grants of $200,000 each have been allocated by the Chrysler Corporation and the Ford Motor Company for the expansion of the Automotive Crash Injury Research program in the department of public health and preventive medicine, Cornell University Medical College. The money will be used to further research in the interest of the traveling public and the automobile industry. The program on causes of injury in automobile accidents has been supported by the Commission on Accidental Trauma of the Armed Forces Epidemiological Board of the U. S. Department of Defense and the U. S. Public Health Service. The major purposes of this research are: (1) to obtain scientifically meaningful information on what happens to the occupants of vehicles at the time of an actual crash on the highway and (2) to see whether there are any definite correlations between particular patterns of injury and vehicular design. An interstate cooperative research program has been established with state medical societies, departments of public health, police and traffic enforcement agencies in North Carolina, Virginia, Maryland, Connecticut, Indiana, Minnesota, Arizona, Vermont, and the city of Minneapolis. Texas was scheduled to join the group in October.

OHIO

Society News.—On Dec. 14 at 8 p. m. the Cincinnati Society of Neurology and Psychiatry will present Dr. Edgar A. Bering Jr., director, Neurosurgical Research Laboratory, Children's Medical Center, Boston, who will consider the physiology of the cerebral spinal fluid.

Personal.—At Camp Ho Mita Koda in Geauga County, Dr. Henry J. John, Cleveland, was presented with a plaque honoring his 25 years as founder and president of the camp. Groups of 60 diabetic children at a time attend the camp in each of two month-long sessions.——Dr. Howard P. Taylor has been appointed to take charge of the new obstetrical department of the Cleveland Clinic, which will include on its staff Drs. Albert C. Lammert and James S. Krieger, of Cleveland.——Dr. Albert B. Sabin, professor of research pediatrics, University of Cincinnati College of Medicine, was recently invited to lecture at the universities of Lisbon and Oporto in Portugal. He planned to lecture also in France, Sweden, England, and Ireland.

TEXAS

Pediatric Consultant Needed.—The merit system council for the Texas State Department of Health announces an examination for a senior pediatric consultant (salary range, $660-$810; minimum qualifications: (1) M.D. degree, (2) one year's internship in an approved hospital, (3) three years' experience in pediatrics including at least one year's residency in pediatrics, and (4) licensure to practice medicine in Texas. For application write: Merit System Council, 814 Littlefield Bldg., Austin.

Cancer Fund.—Mrs. Mildred Didrikson Zaharias, recently hospitalized for the treatment of cancer, has established the Babe Didrikson Zaharias fund, with offices at University Station, Galveston. The purpose of the fund is not to support research but to make available basic materials and technical personnel necessary for the efficient operation of tumor clinics and for the purchase of equipment necessary in the treatment of malignant diseases. Dr. Hyman W. Paley, Galveston, executive secretary of the fund, announces that, although it will be several months before the fund is in a position to process them, applications will be received at the office of the fund in Galveston.

VIRGINIA

Oto-Ophthalmologists on Cruise.—The Virginia Society of Ophthalmology and Otolaryngology is sponsoring a convention cruise to Havana and Nassau on May 26 to June 2, 1956. Sailing from and returning to Norfolk, the "Queen of Bermuda" will serve as the hotel for the trip. Fare for seven days will be $165 and up per person. Reservations may be made with the United States Travel Agency, Inc., Washington, D. C. Dr. Carl C. Cooley, Medical Arts Building, Norfolk, is publicity chairman for the cruise.

WASHINGTON

Fellowships in Pediatric Cardiology.—One or two fellowships in pediatric cardiology will be available beginning July, 1956, at the Children's Orthopedic Hospital, Seattle. Training will be in conjunction with the department of pediatric cardiology, University of Washington School of Medicine, Seattle. The salary is open. Applicants should have a minimum of two years in pediatrics. Direct correspondence to Dr. Robert A. Tidwell, the Children's Orthopedic Hospital, 4800 Sand Point Way, Seattle 5.

WEST VIRGINIA

Society News.—Newly elected officers of the West Virginia Tuberculosis and Health Association include: Dr. Harold H. Howell, Madison, president (reelected); Mr. Oscar Andre, Clarksburg, vice-president; and Mrs. W. H. Levell, Oak Hill, secretary.——Dr. James P. McMullen, Wellsburg, president, West Virginia State Medical Association, has appointed a committee to confer with a similar committee from the West Virginia Hospital Association in preparing for the medical licensing board a "statement of principles and procedures to comply with the law in the best interests of the public concerning the legality of certain policies employed by hospitals in the collection of medical and hospital fees." The members of the committee from the medical association are Drs. Thomas G. Reed, Charleston; Charles E. Watkins, Oak Hill; and Delivan A. MacGregor, Wheeling.

New Health Center in Huntington.—Dr. Leonard A. Scheele, Washington, D. C., surgeon general of the U. S. Public Health Service, will be the speaker at 8 p. m., Dec. 14, at dedicatory ceremonies for the new health center in Huntington. His address will be delivered at the Huntington Central High School. Open house at the health center, 2-5 p. m., will precede the dedicatory exercises. Building of the new health center at 1336 16th St. was begun in September, 1954. Construction costs totaled more than $250,000. Matching funds for use with a Hill-Burton allocation were provided by the Cabell County court, the city of Huntington, the Junior League, and the Huntington Heart Association. The large one-story building will house the combined health department, formerly quartered in both the Court House and the City Building, the Cancer Information Center, the Huntington Heart Association, the Children's Clinic, and the Baby Clinic.

Personal.—Dr. Ralph H. Zemer, clinical director of the Huntington State Hospital, has been named superintendent of the West Virginia Training School at St. Marys to succeed Dr. Russell L. Heinlein, who resigned to enter private psychiatric practice in Parkersburg.——The following doctors were recently elected to honorary life membership in the West Virginia State Medical Association: Guy H. Michael, Parsons; Harry S. Keister, Fairmont; William A. Adams, Parkersburg; Stephen W. Bull, Spencer; Ludwig Frank, London, England; and Ray Kessel, Ripley.——Dr. and Mrs. Karl J. Myers Jr., Philippi, have enlisted for a three year period as missionaries to Nigeria, West Africa. Mrs. Myers is the former Mary Elizabeth Lawton, graduate of the Woman's Medical College of Pennsylvania, Philadelphia. Dr. Myers and his family will attend language school at Oyo, before reporting for duty at the 70-bed Baptist Hospital at Ogbomosho.——At a technical lecture sponsored by Charleston General Hospital, Dr. Arthur A. Shawkey, first Charleston physician to practice pediatrics, received from members of the Kanawha Medical Society an engraved plaque in recognition of his 55th year as a practitioner in that city. Dr. Shawkey has served as president of the Kanawha Medical Society and has held office in the West Virginia State Medical Association. The speaker was Dr. Harry C. Shirkey of Cincinnati, who presented "Childhood Diseases."——Dr. Robert W. Love, Moorefield, who has served Hardy County for 52 years, recently announced his retirement from practice. Dr. Love spent two years with the Gran Chaco Indians of Paraguay, South America, as a medical missionary, before coming to Moorefield. He has been an elder in the Presbyterian church for 53 years, a member of the school board, and has served as head of the Red Cross, president of the chamber of commerce, a member of the draft board during World War I, and an examiner during World War II. He is a past-president of the Potomac Valley Medical Association and has been a member of the house of delegates of the West Virginia State Medical Association.

WISCONSIN

Survey of Epilepsy.—A statewide survey of the epilepsy problem was initiated this fall by the rehabilitation division of the state board of vocational and adult education. Made possible by funds from the Wisconsin Epilepsy League and the Department of Health, Education, and Welfare, the study will verify the number of epileptics in Wisconsin, now estimated at 14,000. A study of employer acceptance of the epileptic will be made to ascertain attitudes and beliefs that limit job opportunities.

University News.—Marquette University School of Medicine, Milwaukee, has reorganized its cardiopulmonary laboratory at the Milwaukee County Emergency Hospital. The laboratory specializes in the cardiac catheterization technique and in the study of pulmonary function. Dr. John H. Huston is physician in charge, and physicians from the departments of pediatrics and surgery have been added to the group of heart specialists at the laboratory. The laboratory serves as a diagnostic and research center for the cardiovascular division and offers educational opportunities for young physicians, medical students, and nurses.

GENERAL

Casselberry Prize.—The American Laryngological Society announces that, a sufficient sum having accrued from the Casselberry fund (for encouraging advancement in the art and science of laryngology and rhinology), this sum is now available, in part or as a whole, for a prize award. Theses must be in the hands of the secretary, Dr. Harry P. Schenck, 326 S. 19th St., Philadelphia, before March 1, 1956.

Cerebral Palsy Foundation.—To accelerate the research attack on cerebral palsy, the United Cerebral Palsy Research and Educational Foundation was recently established by United Cerebral Palsy and a group of industrialists. The foundation will seek gifts from industry, corporations, and foundations to be added to funds set aside for research and training by United Cerebral Palsy and its nationwide network of affiliates, each of which allocates a percentage of contributions for the national program.

Geriatrics Awards.—The Ciba Foundation for the Promotion of International Cooperation in Medical and Chemical Research, 41 Portland Pl., London, W. 1, invites papers on experimental research into basic problems of aging. Five awards, of an average value of £300 each (about $840), are available for the period 1955-1956. Entries must be received by G. E. W. Wolstenholme, director, not later than Feb. 10, 1956. The work submitted should not have been published before July 31, 1955. Papers should not be more than 7,000 words in length, and a summary in English not exceeding in words 3% of the length of the paper must be attached.

Literature on Psoriasis Requested.—The Biological Sciences Foundation, a nonprofit association at the Hillyard House, 1011 New Hampshire Ave., N. W., Washington 7, D. C., which is compiling a comprehensive bibliography on psoriasis (available during the latter part of this year, without charge to members of the medical profession), is interested in receiving communications regarding unpublished papers and also reprints of papers for its files. The foundation's recent conference on psoriasis at the New York Academy was attended by faculty members from the University of Michigan Medical School, Ann Arbor, Harvard Medical School, Boston, Columbia University College of Physicians and Surgeons, New York, and some 20 other scientists who had done work on psoriasis.

Publications on Rheumatic Fever.—The Helen Hay Whitney Foundation, 525 E. 68th St., New York 21, has announced the compilation of the following publications in the field of rheumatic fever and rheumatic heart disease: (1) a directory of facilities for care of patients with rheumatic fever and rheumatic disease (first issued by the foundation in December, 1954, the directory went into a second edition in April, 1955); (2) bibliographies on various aspects of rheumatic fever, for the use of professional workers in the field; and (3) a list of publications on rheumatic fever for lay persons, compiled in response to requests from physicians for such material and intended to save the physician's time in selecting suitable literature for education of the patient's family.

Nominations Invited for Hunter Award.—The American Therapeutic Society, which annually presents the Oscar B. Hunter Memorial award in honor of its late secretary. Dr. Oscar B.

Hunter of Washington, D. C., invites nominations for the 1956 award. The award, made in recognition of an outstanding contribution or series of contributions to therapy by an individual or a team of workers, seeks to bring recognition to those who have not received distinguished awards for their work. The term "therapy" is used in a broad sense, to include the use of any drugs, procedure, or device of benefit in the treatment of patients. The award was this year presented to Dr. Jonas E. Salk, who spoke at the 56th annual meeting of the American Therapeutic Society at Atlantic City, N. J., June 4. The deadline for receiving nominations for the 1956 award is Feb. 1, 1956. Nominations may be sent to Dr. Harry E. Ungerleider, Chairman, Oscar B. Hunter Memorial Award Committee, 393 Seventh Ave., New York 1.

Indian Health Service.—According to the U. S. Department of Health, Education, and Welfare, 30 Indian youths from 12 states have entered training at Phoenix, Ariz., to aid in sanitation work among their people. The course is part of a program to improve health conditions among the American Indians and Alaskan natives. After six weeks of intensive training in sanitation and hygiene, the Indians will be assigned to assist Public Health Service sanitary engineers on Indian reservations in Arizona, Colorado, Idaho, Minnesota, Montana, New Mexico, North Carolina, North Dakota, Oregon, South Dakota, Wisconsin, and Washington. The training program, operated with the cooperation of the Arizona State Health Department, is financed through funds appropriated to HEW for public health and medical services for the Indians. Dr. James R. Shaw, head of the Indian health program in the Public Health Service, states, "The Indian people have 8 times more typhoid, 25 times more infectious hepatitis, and 22 times more dysentery than prevails among the general population. These conditions are due in large measure to the fact that many Indians have only polluted water to drink and are without adequate sanitary and sewage disposal facilities." A similar course for native sanitarian aides in Alaskan villages was scheduled to start at Nome Oct. 17.

Society News.—Dr. Emma S. Moss, New Orleans, was recently installed as president of the **American Society of Clinical Pathologists**; Dr. John L. Goforth, Dallas, Texas, was made president-elect. The 1956 convention will be held in Chicago. ——At the annual meeting of the **American Association of Obstetricians and Gynecologists** the following officers were elected: Dr. Lawrence M. Randall, Rochester, Minn., president; Dr. F. Bayard Carter, Durham, N. C., president-elect; Dr. Raymond A. Gillis, Pittsburgh, vice-president; Dr. Ward F. Seeley, Detroit, treasurer; Dr. Frank R. Lock, Winston-Salem, N. C., secretary; and Dr. E. Stewart Taylor, Denver, assistant secretary. The 1956 annual meeting will be held at the Homestead, Hot Springs, Va., Sept. 6-8.——Newly elected officers of the **Rocky Mountain Radiological Society** include: Dr. Maurice D. Frazer, Lincoln, president; Dr. John S. Bouslog, Denver, president-elect; Dr. Capres S. Hatchett Jr., Amarillo, Texas, first vice-president; Dr. Ralph C. Moore, Omaha, second vice-president; and Dr. John H. Freed, Denver, secretary-treasurer. The next meeting of the society will be held at the Shirley-Savoy Hotel, Denver, Aug. 16-18, 1956.——Newly elected officers of the **Association of Life Insurance Medical Directors** include: Dr. Ralph R. Simmons, Des Moines, Iowa, president; Dr. Edson E. Getman, New York, president-elect; Dr. Norman J. Barker, Hartford, Conn., vice-president; Dr. Henry B. Kirkland, Newark, N. J., secretary; and Dr. J. Grant Irving, Hartford, Conn., treasurer.——The **American Academy of Ophthalmology and Otolaryngology** recently chose Dr. Erling W. Hansen, Minneapolis, president-elect; Drs. M. Hayward Post, St. Louis, Henry L. Williams, Rochester, Minn., and Walter E. Atkinson, Watertown, N. Y., vice-presidents; and Dr. William L. Benedict, Rochester, Minn., executive secretary (reelected). Dr. Albert C. Furstenberg, Ann Arbor, Mich., is president.

LATIN AMERICA

Ophthalmologic Congress in Chile.—The fifth Pan American Congress of Ophthalmology will be held in Santiago, Chile, Jan. 9-14, 1956, under the auspices of the Pan American Association of Ophthalmology, of which Dr. Moacyr E. Alvaro, São Paulo, Brazil, is president. Dr. Cristobal Espildora Luque of Santiago will be president of the congress. Symposiums will be offered on collagen diseases, glaucoma, infantile glaucoma, secondary glaucoma, detachment of the retina, psychosomatic ophthalmology, tropical diseases, physiopathology and surgery of the crystalline lens, plastic surgery, visual fields and neuro-ophthalmology, and intraocular tumors. Symposium participants from the United States will include: Drs. John M. McLean, Frank H. Constantine, and Algernon B. Reese, New York; A. Edward Maumenee, San Francisco; Lorenz E. Zimmerman, Washington, D. C.; Irving H. Leopold and P. Robb McDonald, Philadelphia; William L. Benedict, Rochester, Minn.; Peter C. Kronfeld, Derrick T. Vail, and David Shoch, Chicago; Elmer J. Ballintine and Lorand V. Johnson, Cleveland; H. Saul Sugar, Detroit; Charles L. Schepens and L. Harrell Pierce, Boston; Harold F. Falls, Ann Arbor, Mich.; Robison D. Harley, Atlantic City, N. J.; and Theodore F. Schlaegel Jr., Indianapolis.

FOREIGN

International Meeting on Librarianship.—At its meeting in Brussels, Belgium, Sept. 10, the International Congress of Libraries and Documentation Centres confirmed the wish, expressed at the first international congress of medical librarians (London, 1953), that an international association of medical libraries and documentation centers be created as soon as possible. To this end, the congress requests that the national associations of librarians and documentalists create medical sections and establish close cooperation with the medical profession for the development and coordination of their common interests.

Electron Microscopes for Neurological Research.—Three RCA electron microscopes were recently purchased by the new Institute for Neurology and Brain Research, Caracas, Venezuela, of which Dr. H. Fernandez-Moran is director. The microscopes will be used in research studies. The institute's projected electron microscopy will utilize the Ultramicrotome, developed recently by Dr. Fernandez-Moran which, using a diamond knife, produces ultrathin serial sections of biological tissue, bone, metal, crystal, and other hard materials.

Improved Health in Western Europe.—According to the Metropolitan Life Insurance Company, western Europe's general health, as gauged by prevailing mortality and morbidity conditions as well as by life expectancy, is better than ever, despite the relatively short period that has elapsed since the widespread privation of food, clothing, shelter, and medical services during *World War II. Each of the countries studied established a new* minimum death rate during the postwar period: the death rate in France fell from 13.5 per 1,000 in 1946 to 11.9 in 1954, as compared with 15 per 1,000 in the immediate prewar period; in Italy the death rate was reduced from 12.1 to 9.0 per 1,000 between 1946 and 1954, which compared with an average of about 14 per 1,000 in 1937-1939; and new low death rates were cited for Austria, Belgium, Denmark, western Germany, the Netherlands, Norway, Portugal, Spain, Sweden, Switzerland, England and Wales, and Finland. Many of these countries also reported new records for life expectancy. The gains are attributed mainly to such planned activities as the restoration, soon after the war, of medical, hospital, and public health services and the subsequent expansion and improvement of these services. Wide use of the recent advances in medicine, including the antibiotics and other drugs, and a greatly increased food supply, which has raised the nutritional level of the population, also have been important factors.

CORRECTIONS

Studies with Glucagon.—In the article entitled "Studies with Glucagon in Patients with Insulin Sensitivity" in THE JOURNAL, Nov. 12, 1955, in the legend to figure 4 on page 1100 the word "glucagon" appears five times and only in the first line of the legend is it properly used. The last four times in this legend the word "glucagon" should have been "insulin."

Cost of British Health Service.—In the letter from England entitled "Nation's Health" in THE JOURNAL, Nov. 19, 1955, page 1231, the approximate per capita cost of the National Health Service should have been $31.70 instead of $317.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1956 Annual Meeting, Chicago, June 11-15.

1956 Clinical Meeting, Seattle, Nov. 27-30.

1957 Annual Meeting, New York, June 3-7.

1957 Clinical Meeting, Philadelphia, Dec. 3-6.

Annual Congress on Industrial Health, Sheraton-Cadillac Hotel, Detroit, Jan. 25-24. Mr. Clark D. Bridges, 535 N. Dearborn St., Chicago 10, Acting Secretary.

American Academy of Obstetrics and Gynecology, Conrad Hilton Hotel, Chicago, Dec. 13. Dr. C. Paul Hodgkinson, 116 South Michigan Blvd., Chicago, Secretary.

American Academy of Orthopaedic Surgeons, Palmer House, Chicago, Jan. 28-Feb. 2. Dr. John R. Norcross, 122 South Michigan Blvd., Chicago 3, Secretary.

American Society for Surgery of the Hand, Chicago, Jan. 27. Dr. George V. Webster, 1145 East Green St., Pasadena 1, Calif., Secretary.

Eastern Section, American Laryngological, Rhinological and Otological Society, Boston, Jan. 13. Dr. John A. Murtagh, Dartmouth College, Hanover, N. H., Vice President.

Los Angeles Midwinter Medical Convention, Biltmore Hotel, Los Angeles, Jan. 3-5. Dr. Paul D. Foster, 1925 Wilshire Blvd., Los Angeles 58, General Chairman.

Middle Section, American Laryngological, Rhinological and Otological Society, Netherland Plaza, Cincinnati, Jan. 16. Dr. William H. Craddock, 2328 Auburn Ave., Cincinnati 19, Vice President.

Neurosurgical Society of America, Hotel Key Biscayne, Key Biscayne, Miami, Fla., Jan. 18-21. Dr. Lester A. Mount, 700 West 168th St., New York 32, Secretary.

Radiological Society of North America, Palmer House, Chicago, Dec. 11-16. Dr. Donald S. Childs, 713 E. Genesee St., Syracuse 2, N. Y. Secretary.

Regional Meetings, American College of Physicians:

Winston-Salem, N. C., Dec. 8. Dr. Elbert Persons, Duke Hospital, Durham, N. C., Governor.

Shreveport, La., Jan. 14. Dr. M. D. Hargrove, 803 Jordan St., Shreveport, La., Governor.

Philadelphia, Jan. 20. Dr. Thomas M. McMillan, 330 South 9th St., Philadelphia 7, Governor.

Saskatoon, Sask., Feb. 3-4. Dr. C. H. A. Walton, Winnipeg Clinic, Winnipeg, Man., Canada, Governor.

Sectional Meetings, American College of Surgeons:

Jacksonville, Fla., Hotel George Washington, Jan. 16-18. Dr. Kenneth A. Morris, 2522 Oak St., Jacksonville 4, Fla., Chairman.

South Atlantic Association of Obstetricians and Gynecologists, Hollywood Beach Hotel, Hollywood, Fla., Jan. 28-Feb. 1. Dr. C. H. Mauzy, Bowman Gray School of Medicine, Winston-Salem, N. C., Secretary.

Southern Section, American Federation for Clinical Research, Jung Hotel, New Orleans, Jan. 20. Dr. John H. Moyer, 1200 M.D. Anderson Blvd., Houston, Tex., Secretary.

Southern Section, American Laryngological, Rhinological and Otological Society, The Shamrock, Houston, Texas, Jan. 27-28. Dr. J. M. Robison, 1304 Walker Ave., Houston 2, Texas, Chairman.

Western Section, *American Federation for Clinical Research*, La Playa Hotel and Golden Bough Theater, Carmel, Calif., Jan. 25. Dr. B. H. Scribner, Veterans Administration Hospital, Seattle 8, Washington, Secretary.

Western Section, American Laryngological, Rhinological and Otological Society, County Medical Society Bldg., San Francisco, Jan. 21. Dr. David D. DeWeese, 1216 S.W. Yamhill St., Portland, Ore., Vice President.

Western Society for Clinical Research, Carmel-by-the-Sea, Calif., Jan. 27-28. Dr. Arthur J. Seaman, *University of Oregon Medical School*, Portland 1, Ore., Secretary.

FOREIGN AND INTERNATIONAL

All India Medical Conference, Jaipur, India, Dec. 26-28. Dr. B. N. Consul, Association Bldg., S.M.S. Hospital Premises, Jaipur, India, Organizing Secretary.

Canadian Medical Association, Quebec, P. Q., *Canada, June 10-14, 1956.* Dr. Arthur D. Kelly, 150 St. George St., Toronto 5, Ont., Canada, Secretary.

Conference of International Union for Health Education of the Public, Rome, Italy, April 27-May 5, 1956. Mr. Lucien Viborel, 92 rue St. Denis, Paris 1er, France, Secretary-General.

Congress of International Anesthesia Research Society, Miami Beach, Fla., U.S.A., April 9-12, 1956. For information write: Dr. R. J. Whitacre, 13951 Terrace Road, Cleveland 12, Ohio, U. S. A.

Congress of International Association of Limnology, Helsinki, Finland, July 26-Aug. 7, 1956. For information address: Dr. H. Luther, Snellmansgatan 16 C 36, Helsinki, Finland.

Congress of International Association of Logopedics and Phoniatrics, Barcelona, Spain, Sept. 3-7, 1956. Dr. J. Perello, Provenza 319, Barcelona 9, *Spain, Secretary-General.*

Congress of International Society of Hematology, Hotel Somerset, Boston, Mass., U.S.A., Aug. 27-Sept. 1, 1956. Dr. W. C. Moloney, 39 Bay State Road, Boston, Mass., U.S.A., Secretary.

Congress of Latin Society of Ophthalmology, Madrid, Spain, April 24-28, 1956. For information address: Dr. Costi, Montalban 3, Madrid, Spain.

European Congress of Allergology, Florence, Italy, Sept. 12-15, 1956. Prof. Umberto Serafini, Instituto de Patologia Medica, Viale Morgagni, Florence, Italy, Secretary-General.

European Congress of Cardiology, Stockholm, Sweden, Sept. 10-14, 1956. Dr. Karl Erik Grewin, Sodersjukhuset, Stockholm, Sweden, General Secretary.

European Symposium on Vitamin B_{12}, Hamburg, Germany, May, 1956. For information write: Doz. Dr. H. Bauer, Nervenklinik, Hamburg-Eppendorf, Germany.

Inter-American Congress of Cardiology, Havana, Cuba, Nov. 4-10, 1956. For information address: Dr. Ramon Aixala, Apartado 2108, Havana, Cuba.

International Academy of Pathology, Cincinnati, Ohio, U. S. A., April 24-25, 1956. Dr. F. K. Mostofi, Armed Forces Institute of Pathology, Washington 25, D. C., U. S. A., Secretary.

International Congress Against Alcoholism, Istanbul, Turkey, Sept. 10-15, 1956. For information address: International contre l'Alcoolisme, Case Gare 49, Lausanne, Switzerland.

International Congress of Anthropological and Ethnological Sciences, Philadelphia, Pa., U. S. A., Sept. 2-9, 1956. Dr. William N. *Fenton, National Research Council, Division of Anthropology and* Psychology, 2101 Constitution Avenue, Washington 25, D. C., U. S. A., Secretary-General.

International Congress on Diseases of the Chest, Cologne, Germany, Aug. 19-23, 1956. Mr. Murray Kornfeld, 112 East Chestnut St., Chicago 11, Illinois, U. S. A., Executive Director.

International Congress of Entomology, Montreal, Canada, Aug. 17-25, 1956. Mr. J. A. Downes, Science Service Bldg., Carling Ave., Ottawa, Ont., Canada, Secretary.

International Congress of Gastroenterology, London, England, July 18-21, 1956. Mr. Hermon Taylor, London Hospital, White Chapel, London E.1, England, Honorable Secretary.

International Congress for the History of Science, Florence and Milan, Italy, Sept. 3-10, 1956. Dr. M. L. Bonelli, Instituto di Ottica, Arcetri, Florence, Italy, Secretary-General.

International Congress of Human Genetics, Copenhagen, Denmark, Aug. 1-6, 1956. For information address: The University Institute for *Human Genetics, Tagensvej 14, Copenhagen N, Denmark.*

International Congress of Hydatid Disease, Athens, Greece, Sept. 14-18, 1956. Prof. B. Kourias, Croix-Rouge Hellenique, 1 rue Mackenzie King, Athens, Greece, Secretary-General.

International Congress of Internal Medicine, Madrid, Spain, Sept. 19-23, 1956. Dr. J. C. De Oya and Dr. J. Gimena, Hostaleza No. 90, Madrid, Spain, Secretaries.

International Congress of International College of Surgeons, Palmer House, Chicago, Illinois, U. S. A., Sept. 9-13, 1956. Dr. Max Thorek, 1516 Lake Shore Drive, Chicago, Illinois, U. S. A., Secretary-General.

International Congress of Neo-Hippocratic Medicine, Montecatini, Terme, Italy, May 20-22, 1956. Dr. Valente, 41 Avenue Verdi, Montecatini Terme, Italy, Secretary-General.

International Congress of Paediatrics, Copenhagen, Denmark, July 22-27, 1956. Professor P. Plum, Rigshospitalet, Copenhagen, Denmark, President.

International Congress of Physical Medicine, Copenhagen, Denmark, August 20-24, 1956. Dr. B. Strandberg, Kobenhavns amts sygehus i Gentofte, Dept. of Rheumatology and Physical Medicine, Hellerup, Denmark, Honorable Secretary.

International Congress of Physiopathology of Animal Reproduction and Artificial Insemination, Cambridge, England, June 25-29, 1956. For information address: Dr. Joseph Edwards, Production Division, Milk Marketing Board, Thames Ditton, Surrey, England.

International Congress of Radiology, Mexico, D. F., *Mexico, July 22-28*, 1956. Dr. Jose Noriega, Tepic 126 (2e piso), Mexico, D. F. 7, *Mexico, Secretary General.*

International Congress of World Confederation for Physical Therapy, Hotel Statler, New York, New York, U. S. A., June 17-23, 1956. For information address: Miss Mildred Elson, American Physical Therapy Association, 1790 Broadway, New York 19, New York, U. S. A.

International Genetics Symposium, Tokyo and Kyoto, Japan, Sept. 6-12, 1956. For information address: Secretary, International Genetics Symposium, Science Council of Japan, Ueno Park, Tokyo, Japan.

International Physiological Congress, Brussels, Belgium, July 29-Aug. 5, 1956. For information address: Prof. J. Reuse, Faculte de Medicine et de Pharmacie, 115 Boulevard de Waterloo, Brussels, Belgium.

International Professional Union of Gynecologists and Obstetricians, Madrid, Spain, Sept. 28-29, 1956. Dr. Jacques Courtois, 1 rue Racine, St-Germain-en-Laye (S and O), France, Permanent International Secretary-General.

Latin American Congress of Pathology, Mexico, D. F., Mexico, Dec. 11-17. For information address: Laboratorio de Anatomia Patologica, Instituto N. de Cardiologia, Avenida Cuauhtemoc 300, Mexico 7, D. F., Mexico.

Latin American Congress of Physical Medicine, San Juan, Puerto Rico and Curacao, N.W.1., Jan. 29-Feb. 8, 1956. Dr. Cassius Lopez de Victoria, 176 East 71st St., New York 21, New York, U. S. A., Executive Director.

Medical Women's International Association, Extraordinary General Assembly, Burgenstock, Nidwalden, Switzerland, Sept. 21-23, 1956. Dr. Janet Aitken, 30a Acacia Road, London N.W. 1, England, Secretary.

National Congress of Pediatrics, Cuidad Universitaria, Mexico D.F., Mexico, May 1-5, 1956. Dr. Ignacio Avila Cisneros, Calzada de Madereros No. 240, Mexico 18, D.F., Mexico, Coordinator.

North Queensland Medical Conference, Cairns, North Queensland, Australia, June 25-30, 1956. Dr. W. R. Horsfall, P. O Box 672, Cairns, N.Q., Australia, Secretary.

Pan-American Academy of General Practice, San Juan, Puerto Rico and Curacao, N.W.1., Jan. 29-Feb. 8, 1956. Dr. Arturo Martinez, 54 East 72d St., New York 21, New York, U. S. A., Secretary.

Pan American Congress of Gastroenterology, Havana, Cuba, Jan. 20-27, 1956. For information address: Dr. Norberto M. Stapler, 1267 J. E. Uriburu, Buenos Aires, Argentine, S. A.

Pan American Congress of Ophthalmology, Santiago, Chile, S. A., Jan. 9-14, 1956. Dr. Rene Contardo, Huerfanos 930, Of. 74, Santiago, Chile, Secretary General.

Pan American Congress of Otorhinolaryngology and Bronchoesophagology, San Juan, Puerto Rico, April 8-12, 1956. Dr. C. E. Munoz MacCormick, Apartado 9111, Santurce 29, Puerto Rico, Secretary General.

Pan American Medical Women's Alliance, Santiago, Chile, March 6-13, 1956. For information address: Dr. Eva Cutright, 458 Beall Ave., Wooster, Ohio, U. S. A.

World Congress on Fertility and Sterility, Naples, Italy, May 18-26, 1956. For information address: Prof. G. Tesauro, S. Andrea della Dame, 19, Naples, Italy.

World Medical Association, Havana, Cuba, Oct. 9-15, 1956. Dr. Louis H. Bauer, 345 East 46th St., New York 17, New York, U. S. A., Secretary-General.

EXAMINATIONS AND LICENSURE

EXAMINING BOARDS IN SPECIALTIES

American Board of Dermatology and Syphilology. *Written.* Various centers, July 26. *Oral.* St. Louis, Oct. 12-15. Sec., Dr. B. M. Kesten, One Haven Ave, New York 32.

American Board of Internal Medicine: *Written.* Oct. 15, 1956. Final date for filing application is May 1. *Oral Examinations in 1956.* New Orleans, Feb. 7-10; Los Angeles, April 12-14; Chicago, June 7-9. Final date for filing application for these three oral examinations is Jan. 3. New York City, Sept. 21-25. Final date for filing application is April 1. Exec. Sec., Dr. William A. Werrell, 1 West Main St., Madison 3, Wis.

American Board of Obstetrics and Gynecology: *Written Examination and submission of Case Reports. Part I.* Various locations in United States and Canada, and military centers outside of the Continental United States, Feb. 3, 1956. Final date for filing application was Oct. 1. *Oral and Pathological Examinations. Part II.* Chicago, May 11-20, 1956. Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Written.* January 24-26, 1956. *Practical Examination.* San Francisco, June 18-21, St. Louis, Oct. 20-25. Applications for 1957 written examination must be filed before July 1, 1956. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland 9, Maine.

American Board of Orthopaedic Surgery: *Oral.* Jan. 26-27. Final date for filing application was Aug. 15. *Part I. Oral and written.* Various centers, April 1956. Final date for filing application is Nov. 30. Sec., Dr. Harold A. Sofield, 116 South Michigan Ave., Chicago 3.

American Board of Otolaryngology. *Oral.* Montreal, Canada, May 6-10. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Physical Medicine and Rehabilitation. *Parts I and II.* Chicago, June 16-17. Sec., Dr. Earl C. Elkins, 200 First St., S. W., Rochester, Minn.

American Board of Plastic Surgery. *Entire Examination.* Buffalo, May 13-15. Final date for filing case reports is Jan. 1. Corres. Sec., Mrs. Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8.

American Board of Psychiatry and Neurology: New York City, December, Philadelphia, April 16-18, 1956. Sec., Dr. David A. Boyd, 102-110 Second Ave. S.W., Rochester, Minn.

American Board of Radiology: Deadline for filing applications for the Spring 1956 examination is Jan. 1. Those candidates who will complete their training by June 30, will be eligible to appear at this examination. Sec., Dr. B. R. Kirklin, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Part I.* Centers throughout the United States, in Europe and in the Far East, March 28. Closing date for the March examination was December 1. *Part II.* St. Louis, Dec. 12-13; New Orleans, Jan 16-17; Los Angeles, Feb. 13-14; San Francisco, Feb. 16-17; Durham, March 12-13; Boston, May 14-15 and Philadelphia, June 4-5. Sec., Dr. John B. Flick, 255 S. Fifteenth St., Philadelphia 2.

Board of Thoracic Surgery. *Written.* February 1956. Closing date for filing application was Dec. 1. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2, Mich.

MAGAZINE–TELEVISION REPORT

The following list of current medical articles in mass-circulation magazines and forthcoming network television programs on medical subjects is published each week only for the information of readers of The Journal. *Unless specifically stated, the American Medical Association neither approves nor disapproves of the articles and programs reported.*

TELEVISION

Monday, Dec. 19

NBC-TV, 11 a. m. to 12 noon EST. "Medical and Health News with Howard Whitman," a segment of the "Home" show.

NBC-TV, 9 p. m. EST. "Medic" repeats "Red Christmas," the story of a Christmas office party that leads to a serious automobile accident.

ABC-TV, 9:30 p. m. EST. "Medical Horizons" goes to New York Hospital, Cornell University, for a report on the four functions of a hospital nurse: care of the sick, patient education, training the student nurse, and public health. Presented in cooperation with the American Medical Association.

Tuesday, Dec. 20

NBC-TV, 10:30 p. m. EST. "Big Town" features an interview with Gen. Omar Bradley on what business and industry can do to help solve the problem of the physically handicapped.

MAGAZINES

The American Weekly, Dec. 11, 1955

"Hepatitis," by William Engle

"Medical scientists in great research centers today are working in two special ways to solve the mystery of viruses such as that of infectious hepatitis. One of their aims is to perfect vaccines against virus diseases or synthetic antibodies to attack the viruses."

Collier's, Dec. 9, 1955

". . . 65 and Over"

A preview look at a survey on "Economic Needs of Older People," to be published in January by the Twentieth Century Fund. In answering the question "How Is Their Health?" the article says: "From one tenth to one third of all Americans sixty-five or older are chronically ill, and most persons over sixty have some more-or-less permanent disability or disease."

Coronet, December, 1955

"Dear Doctor . . ."

Contains extracts from a new book with that title, which reproduces "unintentionally funny letters" received by doctors.

GOVERNMENT SERVICES

ARMY

Reserve Participation Possible Prior to Doctor's Active Duty.—Seniors in approved American medical schools planning to enter the Army Reserve Medical Corps after graduation next June can begin earning reserve credits at once if they accept their commissions early this winter. Col. Joseph H. McNinch, chief, personnel division, surgeon general's office, said, "With the emphasis being placed now on Reserve service in today's defense blueprints, this is an important consideration the prospective physician may overlook if he postpones sending in his completed application form to the proper Army officials."

These application forms concern participation in the armed forces reserve medical officer commissioning and residency consideration program now in operation. Under this program, evolved by the Department of Defense and the Selective Service System to insure the continuing supply of properly trained doctors for the nation, the medical senior may combine his military obligation and his intern and residency training. He may have up to three years in residency instruction in the medical specialties needed to safeguard the health of the fighting man.

"Processing of commissions in the Medical Corps, Army Reserve, requires a minimum of two months and in some instances, a longer period," said Colonel McNinch. "Consequently, the sooner the senior or the intern gets his papers in . . ., the earlier he will eliminate any uncertainty about his future plans for military duty and the possibility of any interference with his professional progress. It is possible that the senior who waits too long to file his acceptance of an appointment may have to serve on enlisted status until his commission papers are processed."

Col. James H. Kidder, special assistant to the surgeon general for reserve forces, said, "The many advantages of this fine program stem from the opportunity it offers the senior medical student to know reasonably well in advance how he is going to fit his plans for medical training and practice into his military service. One primary advantage is that the choice of service may be made by the individual rather than by the Department of Defense, so long as this choice is within the desired allocations and proportions required by the services."

NAVY

Hospital Corpsman Earns Ph.D. While on Active Duty.—By attending classes during off-duty hours for about nine and one-half years, hospital corpsman first class Albert D. Jenkins has acquired bachelor, master, and doctorate degrees, conferred by the University of Edinburgh, Scotland, where he met entrance requirements before joining the Navy in January, 1943. He attained a B.S. degree in five and one-half years by attending Boston College and Harvard Medical school while attached to the Naval Hospital at Chelsea, Mass., and by attending the University of Washington while assigned to the Bremerton Naval Hospital. For a masters degree, he attended the University of Hawaii while on duty at the Tripler General Hospital in Honolulu. The subject of his thesis for a masters degree was "Experimental Psychology, the Adult Male." He has acquired a Ph.D. in clinical psychology. All credits for his work in other colleges and universities were transferred to the University of Edinburgh.

Born in 1926, in Portland, Maine, he served aboard a Landing Ship Tank during the invasion of Okinawa; while in service, he was credited with saving many lives when his ship was hit repeatedly and was awarded the Bronze Star medal. During the Korean campaign he served in both Japan and Korea. Jenkins completed training at the Navy Submarine School in April, 1955, and now is assigned to the submarine USS Ray.

Personal.—Lieut. Pauline E. Clarke, who was recently commissioned in the Medical Corps of the Navy, is one of five women doctors in the regular Navy. Lieut. Clarke is presently on duty at the Naval Dispensary, Washington, D. C.

ATOMIC ENERGY COMMISSION

Fellowships in Industrial Medicine.—The U. S. Atomic Energy Commission offers eight fellowships providing advanced training and on-the-job experience in industrial medicine, particularly in relation to the atomic energy industry. The program will be administered by the atomic energy project, University of Rochester (N. Y.) School of Medicine and Dentistry. The fellowships are open to men and women physicians who are citizens of the United States, who have graduated from an approved college of medicine at least two years before beginning tenure of the fellowship, and who are licensed to practice medicine in one of the states or territories of the United States. Successful candidates will be required to have a full F. B. I. background investigation and to be cleared by the commission before award of a fellowship. Applications for the academic year 1956-1957 should be filed before Jan. 1, 1956. It is expected that the selection of fellows will be made on or before Feb. 1, 1956, but fellowships may be assigned at any time at the discretion of the committee. The stipend during a fellowship or academic year is $3,600. The sum of $350 is added to the total stipend for a wife, and $350 more is added for each dependent child. Tuition and laboratory fees, which would be required of students of similar university status, will be paid in academic courses. Certain other expenses incident to the work will be paid when approved by the committee. During the in-plant year of training, the stipend will be $6,000. The fellowship year of academic training may be taken at a university offering an approved graduate course in industrial medicine that can provide special training facilities in the health problems associated with the atomic energy program. The in-plant year of training will be given at A. E. C. contractor installations such as Oak Ridge, Tenn., Los Alamos, N. Mex., Richland, Wash., and other areas where there are major industrial medical units. Address all inquiries to: A. E. C. Fellowships in Industrial Medicine, Atomic Energy Project, University of Rochester, School of Medicine and Dentistry, Rochester 20, N. Y. Attention: Henry A. Blair, Ph.D.

PUBLIC HEALTH SERVICE

Personal.—Dr. T. D. Dublin has been appointed to the staff of the National Institutes of Health, with special assignment to community services programs. He will assist Dr. C. J. Van Slyke, associate director (for extramural affairs), and the staffs of the seven Institutes. Dr. Dublin has been a special consultant to the National Foundation for Infantile Paralysis for planning and organization of the poliomyelitis vaccine field trial. Formerly the executive director of the national health council, Dr. Dublin received his M.D. degree from Harvard University and a Dr.P.H. degree from Johns Hopkins University.

MISCELLANEOUS

Grants-in-Aid.—The Division of Medical Sciences, National Academy of Sciences-National Research Council, is accepting applications for grants-in-aid of research in three specialized fields: 1. The Committee on Problems of Alcohol is interested in fostering research, primarily on the physiological, biochemical, and pharmacological effects of alcohol. Applications should be postmarked not later than Jan. 15, 1956. 2. The Committee for Research in Problems of Sex, concerned with encouraging research primarily on the mechanisms controlling sexual behavior in animals and man, invites proposals involving endocrinological, neurological, psychological, anthropological, phylogenetic, and genetic studies directed toward this objective. Requests will also be considered that deal with the physiology of reproduction or with related biological and biochemical fields. Applications should be postmarked on or before Feb. 1, 1956. 3. The Committee on Drug Addiction and Narcotics invites applications for the support of research in analgesia and addiction and will welcome information on basic research being carried on in these fields. For application blanks, write to the appropriate committee of the Division of Medical Sciences, National Academy of Sciences-National Research Council, 2101 Constitution Ave. N. W., Washington 25, D. C.

DEATHS

Ames, Azel ⊕ Hamilton, Ohio; born in Newton, Mass., Feb. 10, 1903; Columbia University College of Physicians and Surgeons, New York City, 1927; interned at the New York and Presbyterian hospitals in New York City; formerly a resident in surgery at the Cincinnati General Hospital; at one time assistant professor of surgery at the State University of Iowa College of Medicine, Iowa City; specialist certified by the American Board of Surgery; certified by the National Board of Medical Examiners; member of the Society of University Surgeons and the American Trudeau Society; past-president of the Butler County Medical Society and the Hamilton Academy of Medicine; served on the medical service plans committee of the Ohio State Medical Association and on the Butler County Advisory Board of Health; president of the Butler County Tuberculosis and Health Association and past-president of the Ohio Tuberculosis and Health Association; for a short time a lieutenant commander in the U. S. Naval Reserve during World War II; on the staff of the Hughes Memorial Hospital; associated with the Fort Hamilton Hospital and the Mercy Hospital, where he was chief of staff, and where he died Sept. 24, aged 52, of coronary thrombosis.

Luce, Henry Ashley ⊕ Detroit; born Oct. 16, 1874; Detroit College of Medicine, 1905; clinical assistant professor of psychiatry at his alma mater, now known as the Wayne University College of Medicine; member of the House of Delegates of the American Medical Association in 1924 and from 1931 to 1946; charter member and past-president of the East Side Medical Society; past-president of the Michigan State Medical Society and the Wayne County Medical Society; in 1919 president of the Detroit College of Medicine and Surgery Alumni Association; served during World War I; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; fellow of the American College of Physicians; medical director, Michigan Society for Mental Hygiene; in 1938 named to a seven man advisory committee for the expansion of public health activities in Michigan; on the staffs of the Evangelical Deaconess, City of Detroit Receiving, and Harper hospitals, the Eloise Hospital and Infirmary, and the Jennings Memorial Hospital, where he died Oct. 28, aged 81, of pneumonia.

Simpson, Leo Francis ⊕ Rochester, N. Y.; born June 26, 1884; University of Buffalo School of Medicine, 1905; specialist certified by the American Board of Surgery; member of the House of Delegates of the American Medical Association, 1950 and 1951; fellow of the American College of Surgeons and the International College of Surgeons; past-president of the Medical Society of the State of New York, Monroe County Medical Society, and the Rochester Academy of Medicine; associated with the Strong Memorial Hospital, Monroe County Infirmary, and the Park Avenue Hospital; in 1952 awarded an honorary degree of doctor of science by the St. Bonaventure University; died Oct. 31, aged 71, of coronary disease.

Corey, Giles Patterson, Greenville, N. C.; born in Greenville, N. C., Aug. 19, 1925; Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, 1951; interned at the Jefferson Hillman Hospital in Birmingham, Ala., where he served a residency in surgery; appointed a lieutenant (j. g.) in the Medical Corps of the U. S. Naval Reserve on Aug. 31, 1953; reported for active duty on Oct. 30, 1953, at the Naval Auxiliary Air Station, Barin Field, Foley, Ala.; in April, 1954, reported to the USS Antietam; promoted to the grade of lieutenant on July 2, 1954; remained in that assignment until Sept. 2, 1955; died in the Duke Hospital, Durham, Oct. 23, aged 30.

Barstow, William Edwin ⊕ St. Louis, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905; past-president of the Michigan State Medical Society and served as councilor of the Eighth District; past-president of the Gratiot-Isabella Clare Counties Medical Society; past-president of the school board; charter member and past-president of the Rotary Club; for many years active in boy scout work and was given the Silver Beaver award; died in the Providence Hospital, Detroit, Oct. 6, aged 78, of pericarditis and myocardial infarction.

Ahlquist, Richard Elmer ⊕ Spokane, Wash.; Denver and Gross College of Medicine, 1910; also a graduate in pharmacy; governor of the American College of Surgeons; charter member and first president of the Spokane Surgical Society; past-president of the North Pacific Surgical Society; served during World War I; district surgeon for the Union Pacific Railroad Company; on the staffs of the Deaconess Hospital, Sacred Heart Hospital, and St. Luke's Hospital, where he died Oct. 12, aged 67, of carcinoma of the head of the pancreas.

Axelson, Axel U. ⊕ Detroit; Detroit College of Medicine and Surgery, 1918; member of the American Academy of General Practice; an associate member of the International College of Surgeons; on the staffs of the Woman's, St. Joseph's, and Florence Crittenton hospitals; died Sept. 5, aged 66, of ruptured aneurysm of the aorta.

Beebe, Hugh McDowell ⊕ Ann Arbor, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1907; served on the faculty of his alma mater and of the University of Michigan Medical School; fellow of the American College of Surgeons; served during World War I; on the staff of the St. Joseph Mercy Hospital, where he died Oct. 3, aged 72, of myocardial infarction.

Benson, John Charles ⊕ Flint, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1907; past-president of the Genesee County Medical Society; on the staffs of the Hurley, St. Joseph, and McLaren General hospitals; died Oct. 9, aged 77, of aplastic anemia.

Boeckmann, Egil ⊕ St. Paul; University of Pennsylvania Department of Medicine, Philadelphia, 1905; member of the American Academy of Ophthalmology and Otolaryngology; died in Dellwood, Minn., Sept. 3, aged 73, of pneumonia.

Burns, Keith Gillies ⊕ Seattle; Queen's University Faculty of Medicine, Kingston, Canada, 1924; member of the American Trudeau Society and the American Academy of General Practice; on the staffs of the Seattle General and Providence hospitals; died in Parry Sound, Ontario, Canada, July 4, aged 57, of coronary disease.

Cascio, Domenico, Atlantic Highlands, N. J.; Regia Università degli Studi di Messina. Facoltà di Medicina e Chirurgia, Italy, 1923; died in Middletown July 5, aged 59, of cerebral hemorrhage.

Chase, Robert Logan ⊕ Glasgow, Ky.; Western Reserve University School of Medicine, Cleveland, 1943; interned at the Peoples Hospital in Akron, Ohio; served during World War II; on the staff of the T. J. Sampson Community Hospital; died Oct. 9, aged 37, of injuries received in an automobile accident.

Chilton, William Ernest ⊕ Fort Worth, Texas; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1900; fellow of the American College of Surgeons; served during World War I; on the staffs of the W. I. Cook Memorial Hospital Center for Children, City-County Hospital, All Saints Hospital, and St. Joseph's Hospital; died Oct. 27, aged 78, of monocytic leukemia.

Collom, Spencer Allen Jr. ⊕ Texarkana, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1929; fellow of the American College of Surgeons; served during World War II; on the staff of the Texarkana (Texas) Hospital and St. Michael's Hospital in Texarkana, Ark.; co-founder and president of the Temple Memorial Home for Crippled Children; died Oct. 10, aged 51.

⊕ Indicates Member of the American Medical Association.

De Moully, Oliver Martin ⊕ Flasher, N. D.; Marquette University School of Medicine, Milwaukee, 1919; local health officer; died in St. Alexius Hospital, Bismarck, July 26, aged 64, of squamous cell carcinoma.

Dufty, George Watson, Nassau, N. Y.; Albany (N. Y.) Medical College, 1910; for many years county coroner; on the staff of the Samaritan Hospital in Troy; died Oct. 9, aged 72, of a heart attack.

Evans, Thomas Jr., Pittsburgh; University of Pennsylvania Department of Medicine, Philadelphia, 1905; an associate member of the American Medical Association; member of the Medical Society of the State of Pennsylvania; past-president of the Pittsburgh Gynecology Society; served on the staffs of the Pittsburgh, Columbia, and St. Mark's hospitals; died Oct. 23, aged 76.

Forbes, David Arthur, Seattle; Williamette University Medical Department, Salem, Ore., 1907; died in Maynard Hospital Sept. 26, aged 80.

Foster, Eli Norman, Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1903; an associate member of the American Medical Association; served during World War I; died in the Veterans Administration Hospital, Oakland, Oct. 19, aged 75.

Gerry, Frank Henry ⊕ Arlington, Mass.; Middlesex College of Medicine and Surgery, Cambridge, 1920; member of the American Society of Anesthesiologists; at one time school physician; served during World War I; on the staff of Symmes Hospital in Arlington and Chelsea (Mass.) Memorial Hospital; died in Bedford Oct. 25, aged 62, of coronary sclerosis.

Goldstone, Walter ⊕ Brooklyn; Université de Lausanne Faculté de Médecine, Switzerland, 1942; on the staffs of the Cumberland and Prospect Heights hospitals; died Aug. 12, aged 40, in the ship disaster of the Levin J. Marvel on Chesapeake Bay, Md.

Hammond, Walter Jean, Laconia, N. H.; Medical School of Maine, Portland, 1912; member of the New England Society of Psychiatry and the New Hampshire Medical Society; died Aug. 1, aged 74, of acute coronary thrombosis.

Hayman, Charles Stanley ⊕ Boscobel, Wis.; Rush Medical College, Chicago, 1895; died Aug. 11, aged 83, of carcinoma of the prostate.

Hood, William Andrew ⊕ Hickory Grove, S. C.; College of Physicians and Surgeons, Baltimore, 1889; died in the Divine Saviour Hospital, York, Oct. 4, aged 86, of arteriosclerosis.

Knutson, Olaf A., Buxton, N. D. (licensed in North Dakota in 1904); member of the North Dakota State Medical Association; died in Grand Forks Sept. 25, aged 76.

Le Doux, Morris Stirling, Rayne, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1923; member of the Louisiana State Medical Society; fellow of the American College of Surgeons; past-secretary of the Shreveport Medical Society; for a long time on the staff of the Highland Sanitarium in Shreveport; died in the Lafayette (La.) Sanitarium Sept. 28, aged 57.

McCann, Eugene John ⊕ Minneapolis; University of Minnesota Medical School, Minneapolis, 1931; served during World War II; on the staffs of the Veterans Administration Hospital, St. Andrew's Hospital, St. Mary's Hospital, and St. Barnabas Hospital, where he died Aug. 20, aged 51, of carcinoma.

McNeeley, Hugh Lyle, Cleveland; University of Wooster Medical Department, Cleveland, 1909; on the emeritus staff of St. Vincent Charity Hospital, where he died Sept. 16, aged 69, of coronary thrombosis.

Maguire, Richard Aloysius, Somerville, Mass.; Boston University School of Medicine, 1935; interned at the Carney Hospital in Boston; died in West Medford Sept. 9, aged 48, of brain tumor.

Mershon, Glenn Earl ⊕ Mount Carroll, Ill.; Barnes Medical College, St. Louis, 1901; on the staffs of the Savanna City (Ill.) Hospital, Deaconess and St. Francis hospitals in Freeport; died Oct. 8, aged 79, of coronary thrombosis.

Metcalf, Henry Martyn ⊕ Hendrysburg, Ohio; University of Pennsylvania Department of Medicine, Philadelphia, 1905; served on the staff of Elyria (Ohio) Memorial Hospital; died in Albion, N. Y., July 19, aged 83, of coronary occlusion.

Murphy, Lawrence ⊕ Newburyport, Mass.; St. Louis College of Physicians and Surgeons, 1925; died Sept. 22, aged 60, of coronary thrombosis.

Outlaw, Jackson Kent ⊕ Albemarle, N. C.; Syracuse University College of Medicine, 1923; interned at the New York City Hospital; died in the Baptist Hospital, Winston-Salem, N. C., Sept. 28, aged 59, of arteriosclerotic heart disease.

Rochester, Gertrude, New York City; Cornell University Medical College, New York City, 1899; an associate member of the American Medical Association; served on the staffs of the Bellevue, New York Postgraduate, and Manhattan Eye, Ear and Throat hospitals; died in the New York Hospital Nov. 9, aged 77.

Sifritt, Neuman, Marion, Ohio; Eclectic Medical Institute, Cincinnati, 1896; also a pharmacist; for many years county health officer; served on the executive board of the Ohio Public Health Association; died Oct. 16, aged 84.

Speidel, Frederick W. ⊕ Senath, Mo.; Louisville (Ky.) Medical College, 1892; died in the Presnell Hospital, Kennett, July 29, aged 86, of gangrene of the left foot and leg.

Stone, Alvin Alexander, Shaker Heights, Ohio; Western Reserve University School of Medicine, Cleveland, 1913; died Sept. 28, aged 68, of hypertensive cardiovascular disease.

Stone, Theodore Croft, Greenville, S. C.; Medical College of the State of South Carolina, Charleston, 1903; died in the Transylvania Community Hospital, Brevard, N. C., Sept. 24, aged 81, of coronary thrombosis and cardiovascular renal disease.

Tillottson, Squire Fountain, Pilot Mountain, N. C.; North Carolina Medical College, Davidson, 1905; died in the North Carolina Baptist Hospital, Winston-Salem, Sept. 12, aged 72, of myocardial infarction.

Tippet, Walter P. ⊕ Green Bay, Wis.; University of Illinois College of Medicine, Chicago, 1925; served as secretary and president of the Brown-Door Kewanee Counties Medical Society; served during World War I and was decorated with the Croix de Guerre and the Purple Heart; president of the Bellin Memorial staff; trustee of Lawrence College, Appleton; died Sept. 12, aged 60, of coronary disease.

Tolle, Charles Banta ⊕ Pontiac, Mich.; University of Michigan Medical School, Ann Arbor, 1942; interned at the University Hospital in Ann Arbor, where he served a residency in pathology; served in the regular Navy and during World War II; secretary-treasurer of the Oakland County Medical Society; clinical laboratory director at St. Joseph Mercy Hospital; died Oct. 22, aged 37, of arteriosclerosis.

Torrance, Adam Morton, Harpursville, N. Y.; University of Toronto Faculty of Medicine, Toronto, Canada, 1923; member of the Medical Society of the State of New York; served during World War II; health officer, school physician, and surgeon for the Delaware and Hudson Railroad; on the staffs of the City and Our Lady of Lourdes hospitals in Binghamton; died Sept. 25, aged 55, of coronary occlusion.

Van Kirk, Asher W., Seattle; College of Physicians and Surgeons, Baltimore, 1907; served during World War I; died in the Veterans Administration Hospital Oct. 19, aged 73.

Vertuno, Louis Abbott, Oak Park, Ill.; Chicago College of Medicine and Surgery, 1911; on the emeritus staff of the Oak Park Hospital; died in Elgin, Ill., Oct. 13, aged 72, of cerebral arteriosclerosis.

Willis, John Buren ⊕ Mayview, Mo.; Barnes Medical College, St. Louis, 1897; served during World War I; died in the Veterans Administration Hospital, Kansas City, Mo., Oct. 25, aged 81, of coronary occlusion.

Wood, George H. ⊕ Onaway, Mich.; Saginaw Valley Medical College, Saginaw, 1901; served on the staffs of the Delray and Michigan Mutual Industrial hospitals; died in Lansing Sept. 16, aged 81, of coronary occlusion.

AUSTRIA

Serum Proteins in Patients with Concussion.—At the meeting of the Society of Physicians in Vienna on Oct. 7, Dr. E. Neumayer reported that he subjected the serum of 25 patients with cranial trauma (of whom 14 showed clinical signs of concussion, 3 signs of contusion, and 8 no evidence of concussion) to paper electrophoresis. There was dysproteinemia, and, at the end of the first week of illness, there was a further shift in the serum proteins that did not depend on injuries of bone or soft tissues. These findings corresponded with the course of other autonomic reactions after concussion in patients who, at the end of the first week of illness, showed signs of autonomic ataxia. These findings, in combination with the centrally localized trauma, are evidence of the central influence exerted on the relative proportions of the serum proteins. Furthermore, by correlation with the clinical aspect, a criterion was obtained for the presence or absence of the concussion syndrome, since the change in the serum proteins did not occur until after the end of the first week of illness when clinical evidence of concussion was seen.

Dysfunction of Adrenal Cortex.—At the same meeting, Husslein and Schüller reported that disturbances of the menstrual cycle in women, or more or less pronounced abnormalities in the reproductive organs in girls, may be the first symptoms of adrenocortical dysfunction. Because the gynecologist is often the first to be consulted when such a disturbance occurs, he should study these phenomena that otherwise lie in the domain of the internist. An analysis of hormones from the urine is an aid in making the diagnosis. The determination of the neutral 17-ketosteroid and the corticosteroids is an aid to diagnosis. In one of the authors' patients with a postpubertal form of adrenocortical hyperplasia, it was possible to relieve the secondary amenorrhea with cortisone and to obtain a diphasic menstrual cycle. After treatment, the patient, who had been sterile, was able to conceive.

Electrocoagulation of Cervical Erosion.—At the October meeting of the Austrian Society of Gynecologists and Obstetricians in Vienna, Dr. V. Grünberger stated that according to the literature electrocoagulation is the method of choice for the treatment of cervical erosion. It should be preceded by special examinations to rule out carcinoma. The case is described of a 49-year-old woman whose Papanicolaou test was negative on three occasions. Colposcopy repeated after six weeks was also negative for any evidence of cancer. After a year clinical and colposcopic findings and smears raised suspicion. Curettage revealed an epidermoid carcinoma. Reexamination of the old vaginal smears revealed evidence that carcinoma was probably present at the time of the first examination. Cytological diagnoses should therefore be made only by an expert. Follow-up examinations after electrocoagulation are necessary up to the time of healing, which should be complete within about six weeks. Development of carcinoma of the cervix after coagulation is extremely rare.

BELGIUM

Medical Liberty.—A special session of the Belgian Society for International Medical Law was held in Liege to study the international tendency toward institutionalization in medicine. Professor De Busscher spoke in favor of traditional medicine with its spirit of sacrifice, disinterestedness, and implicit obligations of care. In some physicians an unfortunate mercenary spirit has grown up that is a stain on the profession. Patients of the poorer classes need pay only a third of their medical expenses, but this amount should be scrupulously collected so as not to harm the physician-patient relationship. The session had a special significance in view of the protest on the part of Belgian physicians against the recent decisions by the Public Health Administration that all medical fees would be paid directly by the Medical Insurance and Social Security Administrations instead of by the patient and that the physicians of these insurance organizations would check all declarations and certificates issued by treating physicians. Physicians in private practice refused to apply these measures and went on strike, not against the patients but against the administration. They achieved their result by simply not filling out any of the forms required by the two organizations. In the face of this mass movement, the ministry suspended its decision and new negotiators were engaged to arbitrate disagreements between the medical profession and the government.

ENGLAND

Mental Hospitals.—In the *Lancet* of Oct. 29, page 917, Dr. J. Bickford describes the plight of what he calls the medically forgotten patient, that is, the chronic psychotic patient for whom little is done, except to provide essential clothing, food, and shelter. Many elderly patients are retained in mental hospitals for social rather than medical reasons. If they were nursed elsewhere the bed shortage would be greatly relieved. The business of a hospital is to cure patients, not to hoard them, and the sheltering of patients in a hospital without any effort to make them well is a complete denial of the functions of medicine. Dr. Bickford also deplores the temporary solution of the shortage of nurses in mental hospitals. The number of assistant nurses, who have no intention of qualifying, is being multiplied, but nurses of this grade cannot undertake responsible work or supervise treatment. They act merely as custodians. During visits by laymen to mental hospitals, emphasis is placed on the admission wards, convalescent villas, and occupational therapy, but not on the plight of the chronic psychotic patient. The physicians have little incentive to discharge these patients, because, if there are any empty beds, the regional hospital board will fill them up with the unwanted patients of other hospitals or with foreign patients who know no English. The existence of these foreign patients is a problem in British mental hospitals because no verbal contact can be made with them by psychiatrists or nurses. Nearly every hospital has 5 or 10 such patients. Another reason for not discharging patients from the mental hospitals is the possible reduction in the senior nursing staff. The Board of Control does not help the chronic mental patient. It exists to see that patients are not illegally detained. Inspections of hospitals by the board's commissioners sometimes take less than an hour. Research into chronic mental illness is not encouraged because young psychiatrists find work in general hospitals and "domiciliary" visits more rewarding. Psychiatrists rarely have the care of chronic psychotics. About a third of all patients in mental hospitals are permanent inmates. They are clad in shapeless garments, and, if they are allowed out of bed, they never wear shoes. Too often they are regarded as objects of disgust and ridicule, and sometimes it seems that the attention paid them is less than that accorded to the hospital's pigs.

Nuffield Health Centers.—When the new national health scheme was being envisaged before 1948 many health centers were planned. These buildings, in which general practitioners were to treat their patients as part of a group practice system, have remained largely in the blueprint stage owing to the unexpected high cost of the health service. Only a few have been built as experiments by the local authorities in association with the Ministry of Health. This has caused dissatisfaction to many practitioners who thought that they could offer better service to their patients through health centers. There is little possibility of their being built now except in new towns, growing suburbs,

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

and rebuilt areas. An example of careful planning of these centers without excessive cost has been set by the Nuffield Provincial Hospitals Trust. Owing to its initiative and generosity, three health centers have been finished and were officially opened by Lord Nuffield on Oct. 17. These three centers form part of a $728,000 scheme by the trust to provide a comprehensive medical service not under state control to serve an eventual population of 80,000 that is expected to be reached at the new town of Harlow in Essex. Under this scheme the general practitioner service will be integrated with an industrial health service and the proposed new Harlow hospital. It is hoped that three more health centers in the town and two industrial health centers will be provided. In addition to facilities for general practitioners there will also be orthopedic, ophthalmologic, speech therapy, and child guidance clinics and investigation units working in connection with the local hospital. Since November a nonprofit company of industrialists has operated an industrial health service for the 5,766 people working at present in Harlow. In the past there has been some doubt as to whether x-ray and pathology departments should be included in the health centers, because it was feared that they might be uneconomical. At Harlow the Nuffield Trust will probably make the experiment. The centers at Harlow are not health centers as originally envisaged in the terms of the National Health Service, since dentists may practice privately there. The rent of a single furnished room used as an office is $364 per annum, plus a local tax. Physicians must provide secretaries. The trust aims at evolving a pattern of comprehensive medical care in Harlow that may prove a future guide to other communities.

Effects of Smoking.—Oswald and Medvei have conducted an investigation on the effect of cigarette smoking on the incidence of bronchitis, using civil servants as clinical material (*Lancet* **2**:843, 1955). The Civil Service has a large number of employees available for questioning, and groups of similar age, sex, occupation, income, and domestic circumstance, with similar degrees of exposure to the dangers of respiratory infection and atmospheric pollution, can be selected for study. The investigation was limited to the staffs of the Treasury and the Ministry of Supply in London, and, of these, 5,844 clerical workers were interviewed. The age range was 16-65, so that no opinion could be expressed on the effect of smoking on bronchitis in persons over the age of 65. The subjects were classified as smokers if they had smoked five or more cigarettes a day for five or more years; if they had smoked less than this they were classified as nonsmokers. They were further classified as having no pulmonary symptoms; occasional or habitual morning cough or sputum; mild bronchitis; moderate bronchitis; or severe bronchitis. The emphasis in grading was on symptoms and disability. Seventy-six per cent of the employees had had radiographs of the chest taken within the previous five years. Of the 782 employees regarded as having bronchitis, 74% were in the mild, 22% in the moderate, and 4% in the severe group. The most striking feature of the survey was that in every instance the proportion of employees having mild respiratory symptoms and bronchitis was consistently higher among smokers than in nonsmokers. The prevalence of bronchitis was 16% in all smokers and 9.4% in the nonsmokers. For the entire series, 36% of the smokers were free from respiratory symptoms, compared with 53% of the nonsmokers.

Silicosis in Ironworks.—A suit was brought by a molder against an iron foundry for which he had worked for 25 years. The molder worked in a large room with a floor of sand, filling molds with molten iron and opening them when the metal had cooled. In the last process adherent sand was "knocked off" the castings and in the process clouds of sand dust were formed. The worker was also exposed to the sand clouds raised by fellow workers. It was not appreciated until 1950 that this process was dangerous to health and caused fracture of the grains of sand, which, when inhaled, could cause silicosis. By 1946 this worker contracted the disease; two years later it was incurable. By 1954 his expectation of life was only 15 years, although he was in his early 40's. In his suit he stated that he should have been protected by a mask or respirator. At the hearing it was stated that it would require 15 years' exposure to the fine sand particles for incurable silicosis to develop. Although 20 types of respirators were available, it was shown that in the light of recent knowledge only one of them, the Mark IV, would have been effective in filtering out the fine particles, so that if any others had been used they would not have prevented the disease from progressing. The judge ruled that Mark IV respirators should have been provided, and he awarded damages of $26,900 for loss of expectation of life, loss of earning capacity, and inability of the plaintiff to provide for his dependents. The Court of Appeal directed a new trial on the question of whether failure to provide Mark IV respirators was in fact a breach of the employers' obligation in view of the state of knowledge at the time.

Treatment of Tuberculosis.—Aminosalicylic acid combined with isoniazid has been shown to be tuberculostatic in vitro. Dr. J. Clegg has carried out a small pilot study to determine if the compound is effective in the treatment of human tuberculosis and to see how quickly it produces resistance (*Brit. M. J.* **2**:1004, 1955). Because on ethical grounds it was considered undesirable to treat new patients with the new compound, and as it seemed that it would prove of value in patients infected with strains already resistant to streptomycin, isoniazid, and aminosalicylic acid, it was stipulated that the selected patients should (1) have chronic pulmonary tuberculosis, with one or more cavities and a strongly positive sputum; (2) be unsuitable for any treatment other than with antibacterial drugs; (3) have had at least three months' treatment with aminosalicylic acid or isoniazid, alone, or in combination, some time previously; (4) have had no change in treatment in the preceding two months; and (5) be likely to remain under treatment for at least three months. Twenty-five patients were selected, but only 17 completed the required treatment. They were given 600 mg. of the compound daily in three equal doses for three months. In none of them did full resistance to the compound develop. Partial resistance occurred in 10 patients. A lowering of the positivity of the sputum occurred in nearly all patients. There was no change in one case, a marked drop in 10, and sputum conversion in 6. In the last group none had previously had sputum conversion under treatment.

Effect of Hypothermia on Vital Organs.—Although it has been held that no gross alterations in tissue structure can be ascribed to hypothermia, Dr. Phyllis Knocker, of the Witwatersrand Medical School, Johannesburg, Union of South Africa, has shown that histopathological changes do occur in the vital organs of animals subjected to this procedure (*Lancet* **2**:837, 1955). Dogs were anesthetized, and, after laparotomy, biopsy specimens were taken of the liver, kidney, and adrenals. Hypothermia was induced by cooling the dogs with ice and was maintained up to two and a half hours, after which further biopsy specimens were taken. Histopathological changes were seen in the organs examined, even when the animals were not cooled beyond the point generally regarded as ideal for operation. The liver cells showed coarse fatty droplets, poor nuclear staining, loss of glycogen, and congestion of the blood sinusoids. The sudanophil substances in the adrenal cortex were increased and vacuolation occurred in the reticular zone. In the kidney the cells of the lower nephron were full of fat. The accumulation of fat in these organs, which was the chief finding, was attributed to anoxia. Similar changes were found when dogs were submitted to anoxia, using nitrous oxide. In view of these findings Dr. Knocker thinks that hypothermia, far from protecting the patient against operative stress, may actually increase the danger, and she questions the value of hypothermia during operation, even in selected cases.

Body Weight and Marital Status.—Lowe and Gibson (*Brit. M. J.* **2**:1006, 1955) examined the medical records for the last 10 years of 1,685 men and 5,081 women in the age group 20 to 59 employed by two large firms in Birmingham. The information available included weight, height, sex, age, marital status, and, in the case of women, size of family. The weight of the women increased throughout the reproductive period; there was no "middle-aged spread" as popularly supposed. The mean weight of the women increased regularly by about 3 lb. (1.3 kg.) every five years. The weight of the men, who were factory workers and not a true cross section of the population, showed little increase in weight with age. The average weight of the men at age 20 was 149 lb. (67.6 kg.) and, if anything, was slightly less than this at age 65. Comparison with figures compiled earlier in the century suggests that the increase in weight of men formerly stated to occur with age no longer occurred. In each five year age group, married women weighed more than single women, and at corresponding ages married women with children were a little heavier than married women without children. It was concluded that the effect of childbearing was not the sole or even the most important reason for the difference in weight between single and married women.

Dr. Schweitzer Honored.—Dr. Albert Schweitzer, the medical missionary, musician, and philosopher, came to London in October to receive from the Queen the insignia of honorary membership of the Order of Merit. The only other living honorary member is President Eisenhower. After the Harveian Lecture on St. Luke's Day, Dr. Schweitzer was received by Sir Russell Brain, the president of the Royal College of Physicians. Dr. Schweitzer was also made an honorary fellow of the Royal Society of Medicine and of the Royal Society of Tropical Medicine and Hygiene. An honorary doctorate of laws was also conferred on him by the University of Cambridge. During his stay Dr. Schweitzer was the guest of Prime Minister Eden.

Abortion Law.—At the meeting in London in October, the Magistrates Association voted 189 to 148 in favor of a resolution to suggest changes in the present law on abortion. The main object was to frame a resolution to insure that no medical practitioner acting in good faith would be found guilty of an offense when terminating pregnancy to preserve the life of the mother and that therapeutic abortion might be permitted if there was a grave risk of the child's being born mentally or grossly physically defective. Technically, it is still an offense for a medical practitioner to terminate pregnancy for therapeutic reasons.

INDIA

Fluorosis Causing Paraplegia.—S. V. Rao reported (*J. Indian M. Profession* 2:780 [Sept. 6] 1955) a case of paraplegia due to fluorosis. The patient, a 45-year-old man, was admitted to the hospital because of tingling and numbness of both lower extremities, with loss of strength of 18 months' duration. The onset was insidious. Examination revealed loss of power in his lower extremities. His gait was spastic, and he was unable to move about except with the help of a stick. The abdominal reflexes were not elicited. Knee and ankle jerks were exaggerated on both sides. Bilateral ankle clonus was elicited, and Babinski's sign was elicited bilaterally. The patient complained of urgency of micturition and constipation. His spine was rigid in the thoracolumbar region. Roentgenograms of the spine, skull, and pelvis showed areas of sclerosis and exostoses of the pelvic bones. No diagnosis was made on the first admission, and the patient went home against medical advice. About 10 months later a case of paraplegia due to fluorosis with skeletal involvement was reported at a clinical meeting. The symptoms and signs in this case and the reported case were so similar that the patient was asked to report back to the hospital with a sample of his drinking water. The paraplegia had not improved, but he was able to walk with the help of a cane and had regained sphincter control. His drinking water, from a well in his own house, contained 7.2 ppm of fluorine. The fluorine content of his urine (normally 0) and blood was 3.3 ppm and 2.4 ppm respectively. A diagnosis of fluorosis was made. The paraplegia was caused by compression of his spinal cord due to changes in the spine, and the tingling and numbness were caused by pressure on roots and nerves. Treatment in such an advanced case is usually disappointing. The addition of magnesium oxide to the drinking water and boiling to remove the fluorine are recommended. Calcium salts are given to increase the excretion of fluorine, thus decreasing skeletal damage. Vitamin C is given empirically but is probably of no value. Treatment to be effective must be continued for a long time.

Electroretinography.—Dhanda R. P. (*J. Indian M. A.* 25:396 [Oct. 10] 1955) reported that electroretinography is an aid to the diagnosis and prognosis of diseases of the eye, as it provides an index of the functional capacity of the retina, especially in patients in whom the fundus cannot be examined directly due to opacities in the media or gross lesions in the anterior segments of the eye. It records the action potential of the retina when it is stimulated. Minimal light passing through the pupil is enough to stimulate the retina to its full activity.

NORWAY

Health of Older People.—A member of the Norwegian Old Peoples' Health Committee, Prof. Axel Ström has investigated the living conditions of 1,389 persons over the age of 70 years by means of a questionnaire. The subjects lived in 16 rural districts, 6 small towns, and in Bergen, the second largest city in Norway. The district nurses in these 23 areas were given special training for the task of visiting the homes of all these older people and inquiring about their woes and major and minor needs. It says much for the tact with which the nurses carried out this task that less than 2% of the persons questioned refused to cooperate; 79% had one or more complaints concerning their health, the women outnumbering the men in this respect in the ratio of 83 to 74%. The number of persons who had been admitted to hospital in the past year was smaller among those over than among those under 80 years of age. It is possible that in view of the shortage of beds hospitals have been reluctant to admit persons who are over 80 years of age and in need of nursing care rather than active treatment. The ailments complained of included rheumatism (31% of the men and 42% of the women). Its frequency was just as great in those under as in those over 80 years of age. Another common complaint, especially in those over 80 years of age, was giddiness of which 29% of the men and 38% of the women complained. Foot trouble was complained of by 22% of the men and 38% of the women. About 9% of the people over 70 years of age living in rural districts and 11-12% of such persons in the towns were in need of admission to an old age or nursing home.

Sport Injuries.—Dr. Otto Johansen in a survey of the records of all mishaps requiring first-aid treatment by the emergency medical service of Oslo during the period 1946-1948 found that 8% of these mishaps were the outcome of athletic events. Studying the same problem from another angle, Prof. Haakon Natvig has investigated the frequency of sickness leave traceable to sports in the staffs of two industrial concerns. He found that during a five year period 1.9% of all sickness leave could be traced to this factor and that 18.4% of the accidents leading to such leave were the outcome of some sport. The most recent of these investigations, reported in *Tidsskrift for den norske lægeforening* for Oct. 15, 1955, was undertaken by Andersen and Holen, whose material consists of 1,758 persons medically examined during the period 1949-1952. The injury rate averaged 8.9% and was higher in male than in female athletes. The sports most frequently responsible were skiing, soccer, and tennis. The most common lesions were fractures and sprains. The injury rate among men was highest in the age group 17-19 years. At this comparatively tender age, training is still often incomplete and the athletes take chances that older competitors would avoid.

National Association for Dietetics and Health.—In October, Prof. Axel Ström presided over a meeting at which Prof. Haakon Natvig outlined the conditions under which the new National Association for Dietetics and Health has come into being. The nationwide involuntary experiment in dietetics imposed on Norway during the last war yielded invaluable lessons. The remarkable decline in the mortality from certain important diseases during this war created new impulses in the field of dietetics, with special reference to the influence of diet on the cardiovascular diseases. As from Oct. 1, Dr. Nicolay Eeg-Larsen has been secretary general and scientific director of the association. He will collect and evaluate data concerning dietetics for the benefit of physicians, dentists, and teachers of dietetics. The association will have its own publication, entitled *Dietetics and Health,* and will promote research, with regard to the special dietetic requirements of certain groups in the community, such as seamen, fishermen, and the inmates of hospitals.

National Cancer Association.—Every October special meetings are held by the Norwegian National Cancer Association, which is affiliated with all the other important voluntary bodies in the country such as the National Tuberculosis Association and the Red Cross. It promotes cancer research, the provision of hospital beds, health education, and social welfare for the victims of cancer. At its annual meeting in October, special attention was focused on the organization of a lottery, a notice of which is to be sent to every household in Norway and a plan whereby women may now undergo an annual medical examination of the breasts at a charge of 2 *kroner* each time. The object of such an examination is the discovery of any abnormality, not just a fully developed cancer of the breast. The abnormalities found will be dealt with according to the special needs of each patient. It is believed that these examinations are more likely to relieve women's minds than to create any cancerophobia.

PERU

Symposium on Schizophrenia.—At the second Peruvian Journeys on Neuropsychiatry in September, Dr. Juan Francisco Valega, director of the Víctor Larco Herrera Hospital for Mental Diseases of Lima, said that during the 1940's the admission rate for schizophrenia increased steadily year after year, while that for manic-depressive psychosis and general paresis remained unchanged. Statistical data since 1950 are not reliable because admissions for mental diseases had to be greatly curtailed for lack of bed space. Dr. Alfredo Saavedra, associate professor of psychiatry, described a new type of schizophrenia, the endoreactive form in which (1) a severe emotional stress is always a precipitating factor; (2) there are basic changes of the mental states and of the mood; (3) irritability, aggressiveness, isolation, and psychological reactions disproportionate to the provocation are frequent (all these features constitute the so-called dysthymias and do not disturb the consciousness); (4) there is inversion of the affect, unconventional behavior, sudden changes in the behavior pattern, phenomena of depersonalization, increase of the sexual appetite, and loss of ethical and moral values; (5) there are marked autonomic reactions, especially the flushing associated with dysthymia; (6) there is negligible intellectual deterioration (most of the patients are intellectually bright); (7) the patients generally rebel against any type of therapy; and (8) except for the changes in the states of mind, all mental symptoms are episodic in nature, alternating with periods of apparent normality. Dr. Saavedra has observed this type of psychosis in more than 15 patients. He also described patients with atypical schizophrenia; the pseudoneurotic form with an onset that closely resembles hysteria or hypochondria; the form associated with endocrine disturbances of the menses; and forms that in their onset simulate manic-depressive or an epileptic psychosis.

Dr. Mariano Querol stated that insulin, electroshock, relaxing drugs, surgery, ventricular lavage, and psychotherapy, systematically and properly used, will produce fair to excellent results in every schizophrenic patient, the results depending more on the individual patient than on the type of therapy used. There is, however, no etiological treatment for the condition, and the patients who are improved or even apparently cured cannot be considered definitely cured. Chlorpromazine and reserpine are especially useful in the symptomatic therapy of the psychoses, particularly in the control of the anxiety states and in the supportive management of chronic cases. Besides, they greatly facilitate the psychotherapeutic approach to the patient. Dr. Querol and Dr. Horacio Estrabidis reported on clinicoelectroencephalographic correlations in schizophrenia. They studied 15 schizophrenic patients, two of whom also had epilepsy. All had been sick for more than two years and were chosen to undergo electroencephalographic study to reveal possible focal cerebral damage. Thirteen patients showed slight to severe abnormalities in their tracings. They were focal in four and generalized in nine. In only two of the five patients with tracings suggestive of idiopathic epilepsy had the epilepsy been diagnosed. All patients with psychomotor changes, ranging from akinetic to hyperkinetic, showed abnormal frontal lobe tracings, but the pattern varied from patient to patient. Failure to obtain clinical improvement was the rule in all patients whose tracings showed generalized abnormalities, and a follow-up examination of these patients revealed deterioration. On the other hand, of the five patients with focal abnormalities, two made a social recovery. The condition of the two patients with normal electroencephalograms deteriorated.

Dr. Carrillo Broatch reported on the therapeutic results in 250 schizophrenic patients, aged 23 to 79 years, who had suffered from the disease for 5 to 15 years. The treatments used were: (1) electroshock plus ventricular lavage; (2) insulin plus ventricular lavage; (3) electroshock plus insulin, antihistaminics and Cardiazol, anticonvulsant drugs, chlorpromazine, reserpine, corticotropin, or supporting therapy; (4) insulin plus chlorpromazine; (5) chlorpromazine plus Phenergan and phenobarbital; and (6) leukotomy plus ventricular lavage. In order to evaluate the usefulness of ventricular lavage, the author used it in combination with either electroshock or insulin in the management of 110 of their patients. It was performed soon after the electroshock therapy was applied or during the hypoglycemic coma. As soon as the procedure was finished analgesics intramuscularly and antibiotics, in doses depending on the grade of meningeal reaction obtained, were given. The body temperature, pulse rate, and respirations were carefully watched. No grave or fatal complications were observed. Every patient underwent the lavage once or twice a week, receiving 10 to 25 such treatments. Follow-up of all the patients of both groups extended from three to five years except in 20, who were followed for five months. In the group treated with ventricular lavage, there were 10 complete recoveries with no relapses and 22 social remissions. Patients with the catatonic form of the disease were most benefited by this treatment. The results in the other group comprising 140 patients were disappointing—only 6 completely recovered and 19 social remissions were obtained. No one treatment appeared to be better than the others. In this series 22.8% of the patients were benefited by treatment and 77.2% were not. The author concluded that ventricular lavage may be helpful in the management of chronic schizophrenia and should be tried in patients who have not been helped by other procedures.

Symposium on Apoplexy.—At the same meeting it was stated that, besides simple roentgenography, arteriography with iodopyracet was helpful in the diagnosis of the cause of cerebrovascular accidents. According to several speakers the hazards from its use are minimal if the contrast medium is used in quantities of 20 to 40 cc. Likewise, pneumoventriculography, when properly used in certain patients, is a useful measure. Dr. Susy Roedembeck said that authorities do not agree as to the cause of cerebral hemorrhage. She believes that every stroke results from a combination of several cerebral and extracerebral factors, which vary in different patients, so that no generalization can be made. Dr. J. O. Trelles said that he has often found histological evidence that cerebral hemorrhages, clinically regarded as being caused by arterial damage, are instead caused by rupture of a varix, phlebothrombosis, and thrombophlebitis.

Dr. Gino Costa stated that in the emergency management of apoplexy the physician should: (1) see that the patient's position is frequently changed to minimize the development of decubitus ulcers and pulmonary hypostasis, taking care also to prevent postural deformities of the paralyzed extremities; (2) improve the cardiovascular state of the patient by means of cardiac stimulants and coronary vasodilators if indicated; (3) insure adequate pulmonary ventilation and if necessary remove bronchial secretions at short intervals with a bronchial aspirator; perform a tracheotomy or give oxygen and carbon dioxide inhalations; (4) have the patient fed through a tube; (5) insure colon and bladder function by the use of enemas and catheterization if necessary; (6) keep the patient at rest, using chlorpromazine as the drug of choice; (7) give broad-spectrum antibiotics in large doses; and (8) avoid aminophylline, because recent studies indicate that it diminishes the cerebral blood flow. Since nicotinic acid and amyl nitrite cannot be shown to modify the cerebral blood flow, they too should be avoided. When thrombosis is found to be the cause of the stroke, expectant treatment is preferred in most cases. The use of substances that increase the cerebral blood flow is necessary, and 5% carbon dioxide with oxygen must be given. Papaverine and Hydergine can also be given for this purpose. The blood pressure should be normalized, but this must be done gradually. If diabetes or syphilis are causative factors, specific therapy is essential.

In cerebral vascular accidents caused by embolism, anticoagulant drugs are indicated if the services of a laboratory are available, otherwise it is better not to prescribe them. If used, bishydroxycoumarin and ethyl biscoumacetate are preferred. This therapy should be continued as long as the chance of new emboli persists. If hemorrhage is the underlying cause, anticoagulants and rutin are given; 40 cc. of 1% procaine in 500 cc. of isotonic glucose solution (or isotonic sodium chloride solution if the patient is diabetic), with an ampul of Phenergan, may be given by intravenous drip over a period of eight hours. If necessary, this can be repeated daily for several days. Mercurial diuretics are given to prevent cerebral edema. Surgery may be necessary, and a surgeon should be available on short notice. The blood pressure, usually greatly elevated in these patients, must be controlled. Carbon dioxide inhalations are also indicated. In the patient who survives the accident and remains incapacitated, rehabilitation is as important as the emergency therapy. The goals of the rehabilitation program are: (1) to prevent the development of deformities or to treat them if they have already developed; (2) to train the patient to walk again; (3) to teach him to perform the usual activities of daily life and to use the sound hand in simple tasks, trying in the meanwhile to develop the use of the affected hand; and (4) to treat the facial palsy and any existing speech disturbances. Although physicians disagree as to the usefulness of stellate ganglion block, it is helpful in the management of certain cerebrovascular accidents if it is performed within six hours after the onset. When thrombosis is the cause of the stroke, cortisone may be useful.

Dr. E. D. Rocca said that he has used artificial hibernation with encouraging results to control the shock caused by the accident. Dr. J. V. Beranles said that in a series of 134 patients who had suffered from cerebral vascular accidents, the following clinical types were recognized: (1) typical apoplexy characterized by sudden and prolonged loss of consciousness; (2) aggravation apoplexy characterized by a progressive loss of consciousness and a deteriorating general state; (3) cerebromeningeal apoplexy characterized by symptoms of severe meningeal irritation but without loss of consciousness; (4) simple paralytic apoplexy due to involvement of the cerebellum or cerebral trunk characterized by varying paralytic patterns depending on the location of the lesion; and (5) mild and poorly defined forms of apoplexy characterized by transient, mild symptoms and a good prognosis. In his series, 48 patients suffered from typical apoplexy of which 25 died, 13 recovered, and 10 remained invalids; the cause was hemorrhage in 42, thrombosis in 5, and embolism in one. Seventy-one patients had the simple paralytic form of which 53 recovered and 18 remained invalid; the cause was thrombosis in 58, hemorrhage in 6, circulatory disturbances in 6, and embolism in one. All the six patients with mild or poorly defined apoplexy recovered, and vascular lesions other than hemorrhage were found to account for the strokes. Five patients had the cerebromeningeal form, and in all of them hemorrhage was found to be the cause; one died, three recovered, and one remained incapacitated. In four patients the aggravation type of which three died and one recovered was found; hemorrhage and thrombosis were the causes. Only 20 strokes occurred in patients under 39 years of age. The underlying cause of the accidents was embolism in 2, aneurysm in 4, infection in 14, degenerative vascular disease in 43, cardiovascular disease in 45, and undetermined in 26.

SWITZERLAND

Army Medical Corps.—Over a four year period a complete reorganization of the Army Medical Service has been conducted by Brig. Col. H. Meuli, chief physician of the Swiss Army. Simulating wartime conditions, he has decentralized the deposition of military equipment. More effective use has been made of motor transportation without, however, neglecting the transportation of the ill and wounded by railroad. Special railroad cars have been designed for this purpose. In the mountains it is still necessary to use horses and mules for transport. A new department of defense against atomic, bacteriological, and chemical weapons has been created. For purposes of study of the new organization, data were submitted by two Medical Corps training schools and a number of medical "refresher" camps (all Swiss military trainees must take a three week refresher course every year after completion of their initial training). To provide these data, a review was made of the entire Medical Corps in action, from the front-line posts to the medical establishments farthest from the front. Medical trains, special boats, and helicopters were used on this occasion. A blood transfusion service and a psychological department have been developed.

In Switzerland a physician must serve his regular military training as a citizen, after which he goes to noncommissioned officers' school in order to gain the rank of corporal and then to officers' school to become a lieutenant. To give him wider training and teach him what physical efforts are required of all soldiers, a 15 day course has been set up at the Federal School of Sports in Macolin, to be given before the officer training program. An aeromedical service is being developed at Dübendorf. One of its projects is a study of telerecording of electroencephalograms of stunt pilots.

The problem of tuberculosis in soldiers is being studied. There are factors inherent in military groups that favor the development of the disease, but on the other hand the high degree of organization of the military system facilitates the continuous practice of control measures. In the course of one training year, 244 cases of tuberculosis were discovered among the recruits. Fifteen per cent of these cases were discovered at the first physical examination, 46% through the serial roentgenograms taken at the beginning of school, 3% as the result of a tuberculin test, 11% during the course of training, 19% through serial roentgenograms taken after basic training, 5% by change in the tuberculin reaction after basic training, and 1% after military service was completed. On entering the training program, 46 to 52% of the recruits had a positive tuberculin reaction. At the end of training, 3 to 6% of these had a changed reaction and 0.05% of these developed active tuberculosis. More than a third of those whose reaction had changed showed the sequelae of a tuberculosis dating from before service. The cost of the roentgenographic examinations performed in the Army is $60,000 annually. These statistics should intensify the campaign of vaccination.

Poliomyelitis is also a problem in the Swiss Army. In the last seven years, there was a yearly average of eight or nine cases, with zero to two deaths. These figures are low in view of the fact that each year from 275,000 to 450,000 soldiers serve from 8,000,000 to 10,500,000 days. The Swiss Army is made up of militias and is not a professional army. It cannot therefore develop its military medicine as do armies in countries that have military hospitals and a professional medical corps.

Increased Resistance of Leukocytes Due to Stilbene.—Storti and Pederzini were the first to study resistance on the part of leukocytes, although many had considered erythrocyte resistance. These workers noted that leukocyte resistance is greatly increased toward the end of pregnancy and falls to normal levels about a month after delivery. The number of leukocytes increases during pregnancy to reach its maximum in the ninth month, just when resistance also attains its maximum. The authors described experiments (*Schweiz. med. Wchnschr.* 85:949, 1955) proving that this phenomenon is largely due to the elevated estrogen levels of late pregnancy. The leukopenia caused by antimitotic agents may be due to leukocyte resistance. Experimental and clinical administration of stilbene, a synthetic estrogen, allowed continuance of antimitotic therapy longer than was thought possible without the association of estrogen, even in the presence of severe leukopenia.

CORRESPONDENCE

VACCINATION FOR TRAVELERS

To the Editor:—As a local health officer I appreciated the editorial "International Certificates of Vaccination" in THE JOURNAL, Oct. 29, page 852. I am sorry that making the point about smallpox precluded the chance of mentioning the fact that other immunizing procedures are also recorded on this form and suggesting that a physician executing this form has a responsibility to his patient as well as to expediting the federal smallpox control program. Day after day people apply to us for certification and we discover their physician did not discuss (or even discouraged consideration of) typhoid and paratyphoid immunization. Travelers to northwestern South America are advised to ignore yellow fever prophylaxis because it is not required. A physician confronted with these certificates should consider the immunization needs of his patient and not the requirements enunciated by some federal, insular, or territorial health department. Here are almost half a million chances a year for physicians to demonstrate their concern for the health needs of the patient rather than allowing themselves to be identified in their patients' minds as persons carrying out arbitrary dictates of some governmental agency. I would like to suggest that physicians be made acquainted with the mechanism for the U. S. Public Health Service collection of intelligence pertaining to international health hazards, also that the physician become acquainted with the "recommendations" columns of the booklet "Immunization Information for International Travel" (Publication no. 384, Division of Foreign Quarantine of the Bureau of Medical Services, United States Public Health Service).

STERILITY OF LAUNDERED FABRICS

To the Editor:—In a recent article by Watson, Wilson, and Tuuri (Diaper Care in Nurseries, *J. A. M. A.* **155**:1579 [Aug. 28] 1954), the results of tests employing home-washing equipment in a utility area adjoining a hospital nursery were given. The conclusion drawn as a result of that work was that sterility resulted about 80% of the time when diapers were laundered in home-washing equipment by nursery personnel. Those familiar with laundering techniques and the sterilization characteristics relating to the laundry process will recognize that such a level of reduction of total count of micro-organisms associated with soiled textiles is totally inadequate. Watson, Wilson, and Tuuri state that a considerable saving of time of nursing and auxiliary forces is effectuated, in terms of reduced time of diaper handling and inventory record keeping, through the installation and utilization of home-washing equipment directly in the ward, thereby obviating the need for the hospital laundry for this duty or for the professional diaper service. Certainly recommendations purporting sweeping changes involving the health and safety of infants, not to mention the greater factor of contagion in general in hospitals, need to be based on complete and exhaustive evaluation of the bacteriological aspects of all phases of the laundering process. It is our opinion that nothing would be gained by adoption of any procedure involving the use of home-washing equipment by personnel in the hospital nursery who are not versed in the fundamentals of the detergent processes that obtain. The use of 1.5 oz. of powdered laundry soap, which is the normal capacity of home-washing equipment and which is deemed adequate by Watson and co-workers, hardly would be expected to produce the results obtained by professional diaper services using more than twice this quantity of soap and alkaline scouring agents and softened water under carefully controlled conditions. These investigators seemingly have overlooked completely the sterilizing aspect of chlorine bleach, laundry sour, and germicides, which have been in use in professional diaper services for years. Workers in the field of detergency research long have recognized the marked superiority of commercial laundering procedures over home washing in terms of such performance characteristics as soil removal, whiteness retention, and stain removal. These latter factors are, however, quite apart from the fundamental principles under discussion. The bacteriological cleanliness of the laundered fabrics is of prime consideration in this instance; indeed, arguments relating to economy or convenience are not pertinent to the case in point. Studies in the critical evaluation of the bacteriological efficiency of the laundering process have been made by Oesterling and associates (Sterilization in the Power Laundry, *Pennsylvania State Univ. Bull.* **37**:1, 1943) and by one of us (Sherrill, J. C.: A Quantitative Chemical Method for the Assessment of Bacteriostasis in Textile Fabrics Soiled with Nitrogenous Matter, Thesis, Pennsylvania State University, 1952). These studies have delineated the role of various aspects of the washing process on the sterility of the laundered fabric. It is not the purpose of this writing to present new evidence but rather to cite the studies aforementioned. It is believed that a review of these studies is pertinent, since considerable difference in the bactericidal efficiencies of home and professional laundering procedures does exist in fact and since little apparently is known of this disparity.

TABLE 1.—*Reduction in Total Bacterial Count Utilizing Typical Home and Commercial Laundry Procedures*

Laundering Method	Total Counts, per Cu. Cm. Initial	Total Counts, per Cu. Cm. Final	% Decrease in Count
Home-Washing Method			
Home washing equipment; one sudsing, three rinses; 120 F; powdered laundry detergent	220,000	19,000	91.4
Commercial Washing Methods			
Commercial washing equipment; three sudsings, five rinses; 160 F; built soap *	68,000	3,000	95.5
Commercial washing equipment; three sudsings, five rinses; 160 F; built soap, and sodium hypochlorite bleach	195,000	2,500	98.7
Commercial washing equipment; three sudsings, five rinses; 160 F; built soap, sodium hypochlorite bleach, and sour † final rinse	195,000	600	99.7
Commercial washing equipment; three sudsings, five rinses; 160 F; built soap, sodium hypochlorite bleach, and sterilizing sour final rinse	452,000	400	99.9

* Built soap refers to a blend of soap and alkali or alkaline salts. The latter compounds are added to enhance the scouring power of soap in the laundering process.

† Sour refers to a mild acid salt used to neutralize the last traces of alkali not removed by dilution in rinsing.

Proper handling of soiled diapers involves: (1) methods for minimizing growth of micro-organisms and development of odors during storage prior to laundering and (2) laundering methods capable of producing a sterile finished product. These requirements constitute a bacteriological problem of considerable magnitude. The work of Oesterling and associates has thrown considerable light on the sterilizing effect of stages and combinations of stages of professional laundry operations. Studies carried out by the American Institute of Laundering (Technical Report No. 394, 1950) have demonstrated the efficacy of the home washer in the sterilization of fabrics being laundered. Their methods of test are cited briefly. Specimens to be examined were collected in sterile quart jars and reserved in ice pack for examination. A 1.5% nutrient agar was seeded with 1 ml. portions of each sample and maintained at 37 C for 24 hours. Counts then were made using a colony counter in the usual manner. In one series of tests, counts were made of (1) tap water entering the plant, (2) water in equilibrium with the soiled fabrics prior to the start of the laundering process, and (3) water from which the laundered fabrics were removed. Table 1 illustrates the data obtained in the studies previously cited in the assessment of bactericidal power of professional and home-washing processes on ordinary assortments of soiled linens being laundered. Table 1 shows the degree to which sterilization has been accomplished in the home-washing process and in professional laundering processes of varying character. Note that where built soap, sodium hypochlorite bleach, and sterilizing sour have been used, nearly complete (99.9%) reduction in total bacteria counts has been effectuated, as compared to only 91.4% reduction in the home-washing procedure. These studies have been made under controlled conditions, wherein all phases of the washing process were under careful surveillance. The reduction in total bacteria counts achieved under actual operating conditions in typical professional laundry plants wherein special precautions are not taken with details of the washing procedure are shown in table 2. The washing procedures in these instances are not identical in detail in every case, but follow generally the procedure indicated in the last method of table 1, which is optimum. These data are from the work of Oesterling and co-workers. Total bacteria counts were made as described previously. In every case total counts were reduced below levels of total count prevailing in tap water. These data represent a cross section of widely varying locale and operating conditions, all of which come within the meaning of professional laundry practice.

TABLE 2.—*Sterility Achieved in Laundered Textile Fabrics Under Typical Operating Conditions*

Plant No.	Raw Supply (Tap Water)	Total Counts, per Cu. Cm.		% Decrease in Count
		Initial	Final	
1	16	14,500,000	0	100.0
2	23	8,000	4	99.9
3	6	931,000	3	99.9
4	11	13,700,000	8	99.9
5	38	9,250	8	99.9

Experimental evidence is available concerning the sterilizing effect of various steps in professional and home laundry practice against the pathogens Micrococcus (Staphylococcus) aureus, Salmonella (Eberthella) typhosa, and Clostridium welchii. In these tests sections of sterile white cotton sheeting were inoculated with these organisms, and, following a suitable growth period under controlled conditions, the fabrics were subjected to detergency treatments shown in table 3. The percentage decrease in numbers in each organism was determined by a comparison of the total counts of clear water extractions of test specimens prior to treatment and of water taken from the final bath at completion of each treatment. These data are also from the work of Oesterling and co-workers. It may be noted from table 3 that all phases of the professional laundry process are nearly completely effective in terms of sterilization of contaminated fabrics. The same is obviously not the case for the home-washing process. We wish to emphasize that while sterility may be achievable through the use of home-washing equipment, many factors are operating that tend to reduce the bacteriological efficiency of the home-washing process. Such requirements as adequate hot water supply at a temperature of 180 F, properly blended soap and alkali, chlorine bleach, and laundry sour frequently are not available in the hospital nursery. Optimum results in the laundering of soiled textile fabrics require a washing cycle comprising three or four soaping operations, followed by a minimum of four to six deep rinses. Professional laundry practice involves utilization under controlled conditions of all of these factors, many of which are completely impractical in home-washing procedures. All of these factors need to be considered carefully in light of the evidence presented before any precedent involving home washing in hospital nurseries is established.

TABLE 3.—*Sterilizing Effect of Components of Home and Professional Laundry Procedures on Three Pathogens*

Component of Laundry Procedure	% Decrease		
	Micrococcus (Staphylococcus) Aureus	Salmonella (Eberthella) Typhosa	Clostridium Welchii
Home Washing Procedures			
Water at 120 F	61.3	75.9	20.0
Water and powdered laundry detergent at 120 F	99.5	75.0	93.4
Commercial Washing Procedures			
Water at 160 F	99.9	99.9	100.0
Water and built soap at 160 F	100.0	100.0	100.0
Sodium hypochlorite bleach at 160 F (diluted)	100.0	100.0	100.0
Sterilizing sour at 120 F (diluted)	97.8	100.0	68.0

COLOR

To the Editor:—A relatively narrow range of color tones, apparently not exceeding 12 to 14 tints, comprise the colors that create the most congruous or generally beneficial backgrounds in rooms or space, and there is nothing mysterious about them any more than nature is mysterious. They simply are comprised in the median range of the spectrum colors, and the more irritating color tones are not overprevalent in them. These colors also appear as the most popular color tones when average and normally healthy individuals have a choice of selection. These dozen or so tints may be flanked with some 14 to 16 additional color tones in a secondary preferential color range, as seen in the color harmony scale. As one moves from these tints one goes increasingly into what may be called exotic or "cloudy day" or like effects. These so-called exotic tints, although often attention evoking, tend to cause subtle effects or moods that normally healthy individuals instinctively try to avoid. Sex, age, and varying degrees of nervous degeneration—and, to some degree, racial origin—tend to cause variation in the reactions of different individuals to color. Often these variations are quite marked. Combinations of such types of individuals as patients in health care facilities are common. A certain percentage of people, of course, do not have normal color perception, and variations from the normal in the reactions of these individuals to identical colors may account for some of the varying color preferences expressed by different persons. The several types of color blind persons, and some of the primitive peoples who cannot distinguish all the visible spectrum colors, may be expected to express interest in those colors that they can distinguish. Color variation also results when objects are viewed under such lighting as daylight, ordinary incandescent, and fluorescent light. Incandescent light approximates sunlight closely, and no surface can show color that is not in the light rays that fall upon it. The effects of color on people are subtle and continuous. What colors will blend well? The answer depends on several factors. Usually buildings are so oriented that various rooms have different exposures to sunlight. Rooms that face the angle of the sun's rays gain a sense of shade and coolness by adding small portions of tinting color as umber, burnt sienna, or ochre to the sunny shades of background color, which usually is done by the paint manufacturer of standard paint in tints. But paint in tints with similar names, made by different manufacturers, may vary considerably in color. Sunlight effect is enhanced in rooms poor in sunlight by using color tones in which yellow, toned down with white, is present to impart an effect of warm sunlight. Where special conditions need not be met, it is usually best if shading is translucent, in soft brownish-yellows, and near opaque shades are avoided. Of course, there are several ways to control excess daylight or sky glare in rooms with light-colored pastel backgrounds by using shades, translucent curtains, or venetian blinds. Window shades, drapes, and other objects in rooms may be chosen to add color interest as well as to serve practical needs. The objective, of course, is to create a pleasing environment that will cause one to feel comfortable. Incongruous environmental color tends to produce ill-effects in individuals to an extent of causing an unhappy mood or an ill-at-ease or depressed feeling. It may cause eye strain and thus fatigue and may influence mood and will. A basic need in the creating of matter-of-fact color environments in buildings is to have technicians who are well trained in the theory of color and harmony and can cope with the practical needs where the work is to be done. This problem does not always have at hand a perfect solution. The preparation of beneficial color environments is a practical endeavor that calls for sound judgment. It is less a matter of learning something "new" than to understand and utilize what always was good. Those who create color environments exercise a mass influence on the well-being of people.

WHOLE BLOOD TRANSFUSIONS

To the Editor:—In The Journal, Sept. 17, 1955, page 171, Krevans and Jackson described a "Hemorrhagic Disorder Following Massive Whole Blood Transfusions" associated with a fall in platelet level. It is well known that simple reduction of circulating platelets is not enough to produce hemorrhage. Other factors are involved, especially those that injure capillary walls. It is my feeling that one such factor is time alteration of bank blood. Most banks allow blood to be used within 21 days. During this time, even under the best conditions of storage, many leukocytes, erythrocytes, and platelets die and become not only useless but probably toxic in effect. Also, as time goes on, the multiplication of psychrophilic micro-organisms increases the toxic effect of certain units of stored blood. Small as each of these factors may be in one pint, their cumulative effect can be dangerous in massive transfusions. Then, the combination of platelet reduction from the large rapid infusion and capillary injury from the toxic substances produces abnormal bleeding. My practice is to limit the use of bank blood to 14 days. Even after massive transfusions I have not encountered abnormal or otherwise unexplained hemorrhage. It would be helpful to know whether the authors have evaluated this storage time factor of transfused blood and whether they have followed the suggestion in The Journal, July 2, 1955, pages 801 and 802, that 10 cc. of 10% calcium gluconate be given intravenously after each liter of blood in order to counter the effect of large amounts of citrate.

ESOPHAGEAL VARICES

To the Editor:—I should like to comment on a statement made in an editorial entitled "Esophageal Varices," which appeared in The Journal, Oct. 1, 1955, page 484. In discussing the control of esophageal bleeding with the balloon tamponade procedure, it was pointed out that Linton and Warren state that this procedure is "useful in differentiating the source of bleeding, since, if the cardioesophageal tamponade controls the bleeding, then the source of it is esophageal varices and not a peptic ulcer of the stomach or duodenum." Some years ago I published a letter and the photographs of the first case of esophageal bleeding controlled by balloon tamponade reported in this country at the Pennsylvania Hospital (*J. A. M. A.* **138:**908 [Nov. 20] 1948). I referred to some work that had been done on the balloon tamponade. Two of the first six patients who were treated with balloon tamponade for presumed esophageal bleeding later were shown to have active gastric ulcers. The bleeding, presumably from the active ulcers, stopped as completely as had bleeding from esophageal varices when the tamponade tube was used. In all these patients a three lumen tube was used. One lumen was used for gastric suction, the second lumen anchored a mushroom balloon in the cardia of the stomach, and the third balloon provided the esophageal tamponade. By maintaining suction within the stomach I feel that this organ was able to collapse, shrink, and telescope upon itself toward the mushroom balloon in the cardia. This is the only mechanism by which I can explain the cessation of bleeding from these gastric ulcers. I have had the opportunity to see two other patients with gastric ulcers, in one of whom we used the mushroom balloon with gastric suction purposefully to attempt stopping the gastric ulcer bleeding. In this instance we were successful. In the other instance again a bleeding gastric ulcer was presumed to be bleeding esophageal varices, yet the same result was obtained. For this reason I do not feel that the balloon tamponade is always useful in differentiating bleeding of esophageal varices from that of a gastric ulcer.

COBALT ADMINISTRATION AND THYROID ACTIVITY

To the Editor:—As stated in an editorial in The Journal, Aug. 13, page 1371, a difference of opinion has arisen with regard to the effect of therapeutic doses of cobaltous chloride upon thyroid function. I have recently been privileged to observe 10 members of an Italian family, 6 of whom have the hereditary leptocytosis trait to a greater or lesser degree. Each of these patients was given cobaltous chloride in dosages ranging from 25 to 100 mg. per day in the case of two children, aged 5 and 11; and 25 to 125 mg. per day in the instance of three adults, aged 26, 28, and 54. Experimental supplies of cobaltous chloride, furnished in 25-mg. enseals, were used during this study. Gastric irritation accompanied by vomiting was exceedingly common. In every instance, the anemia was improved during the period of cobalt administration. Iron was not given concomitantly. In several patients there was laboratory evidence of thyroid hypofunction. All of the family could not be assembled for physical examination. The subjects showed the following changes prior to and at the end of therapy, which extended from Jan. 25, 1954, to April 27, 1954.

Changes in Patients Given Cobaltous Chloride

Case No.	Age	Sex	Time of Measurement	Hemoglobin Level, Gm. per 100 Cc.	Protein-Bound Iodine, Mcg. per 100 Cc.	Total Cholesterol, Mg. per 100 Cc.	Cobalt, Mg. per 100 Cc.
1	26	F	Before treatment	8.3	4.6	182	0
			After treatment	11.3	3.6	191	40
			2 mo. after treatment	10.7	6.4	169	Tr.*
			3 mo. after treatment	9.1	6.2	230	0
2	11	M	Before treatment	10.8	5.4	...	0

FILTERS FOR RADIATION

To the Editor:—The readers of Dr. Kirsh's valuable article on "Radiation Dangers in Diagnostic Radiology" (*J. A. M. A.* **158:** 1420-1423 [Aug. 20] 1955) may arrive at the conclusion that the use of a filter can reduce the potential genetic damage caused by diagnostic roentgen studies (if such exists). It is of the utmost importance to point out that this is unfortunately not the case. Radiation can produce genetic changes only when it reaches the testes, ovaries, and perhaps the uterus of a pregnant woman. The filter recommended absorbs mainly the superficial component of the x-rays and—in oversimplification—substitutes for the patient's skin. A filter as described in the article reduces thus the x-ray dose to the first few millimeters of the patient's tissues but not to organs located at a greater depth. Though there might be a slight reduction of the dose to the most peripheral regions of the testes, there is certainly none elsewhere in the testes or anywhere in the ovaries when an aluminum filter of 1 to 3 mm. thickness is used. Employment of significantly heavier filters does not help either because adequate blackening of the radiographic film can then only be obtained if one increases the exposures. This cancels any beneficial effect of additional filtration. This statement does not detract from the general value of filters in reducing skin exposure and, indeed, here at this institution almost all diagnostic x-ray machines are equipped with a copper filter of 0.1 mm. thickness for this reason, whereas the fluoroscopes possess an aluminum filter of 3.0 mm. thickness, which serves the same purpose.

BUSINESS PRACTICE

The American Medical Association and the Sears-Roebuck Foundation cooperatively have prepared a brochure entitled "A Planning Guide for Establishing Medical Practice Units." This publication contains practical suggestions on various phases of planning from selection of a site to arrangement of equipment and is available in the libraries of state and county medical society offices. From time to time parts of the brochure, slightly modified editorially, will be reproduced in the Business Practice section of The Journal.—Ed.

WHERE TO LOCATE A MEDICAL UNIT

Having selected the city, town, or small community in which you wish to locate, your first project is to look over the area carefully before selecting a site for your medical practice unit. The central business district, a residential shopping area, a new development, or perhaps a suburb are all possibilities. The selection depends upon your preferences and the type of your practice. A reliable realtor can advise about availability and values of building sites, buildings that can be bought and remodeled, and rental space that can be leased and improved.

If you have picked an area predominantly residential, it would be well to check with the local zoning commission, if one exists, or with the city council to find out whether your medical facility will be permitted. Learn the trends of the city. Avoid an area that will deteriorate or change character in the foreseeable future. If there are no zoning regulations, consider the reactions of your neighbors. Their attitudes can influence early success.

A hospital is generally an important adjunct to a physician's practice. Therefore, the following questions are among those you should ask yourself: Will patients receive better care if the hospital, with its additional diagnostic facilities, is close by? Will patients generally be sent to one hospital or will they be sent to several? Will your travel time between office and hospital be increased unreasonably? If no hospital is accessible would you have to provide emergency facilities?

Your medical facility should be easy for patients to find. It should be located near main arteries of traffic and preferably within a convenient distance to public transportation. Perhaps the ideal location would be a short distance from a main traffic artery, where the building housing your unit can be seen but still be far enough away that noise and traffic is not a problem.

No matter where the medical practice unit is to be located, make sure that the sewer, water supply, electric service, telephone service, and gas service are adequate. In the center of town these questions are largely academic, but they are of prime importance to a location at the edge of an urban area, in a small community, or in an old residence. Keep in mind the fact that if you are too far from any of these services the extension and connection costs can be excessive. Noise from industrial establishments and switch yards, fly and mosquito breeding grounds, and smoke and unsightly surroundings can have an important bearing on the success of your practice unit. Not only the present conditions but also the possible future development should be considered.

MEDICAL FILM REVIEWS

BCG Vaccination Against Tuberculosis: 16 mm., color, sound, showing time 19 minutes. Produced in 1954 by Olympus Productions, Cincinnati, for the American Trudeau Society of the National Tuberculosis Association and the Research Foundation. Procurable on loan or purchase ($147.50) from Research Foundation, 70 W. Hubbard St., Chicago 10.

This film tells of a young doctor who visits a senior physician to ask many questions and learn about BCG vaccination against tuberculosis. The older doctor tells the young physician that he has been using BCG at the hospital for many years and shows his visitor the actual tuberculin testing and BCG vaccination of student nurses. During this demonstration, it is shown how freeze-dried BCG is prepared for use. This vaccine is shown to be standardized and stable. The multiple puncture disk method of vaccination is demonstrated in detail, and it is shown to be simple, effective, and painless and a method that eliminates complications following vaccination. The doctor explains the approved role of BCG vaccination in a complete tuberculosis program and presents the results of carefully controlled studies in the United States as well as some of the results of BCG vaccination throughout the world. The recommendations of the American Trudeau Society for the use of BCG vaccine are presented. This film is recommended for physicians who are interested in tuberculosis control, especially those dealing specifically with the health problems of student nurses, interns, residents, or groups where exposure is greater due to the high incidence of tuberculosis in the local population.

Nurse Please: 16 mm., color, sound, showing time 28 minutes. Sponsored by the National Association for Practical Nurse Education, New York. Produced in 1954 by and procurable on rental ($4.50) or purchase ($140) from Trident Films, Inc., 510 Madison Ave., New York 22.

This is the story of a young mother who, almost by accident, becomes interested in practical nursing and finally achieves a career in this field. Jean Markel is a widow whose only child is the victim of fragilitis ossium. A talk with the director of nurses at the hospital where her son is a patient helps Jean to decide to apply for training in the hospital school of practical nursing. This film then goes on to outline the basic course and fields of study in practical nursing after her application is accepted. In addition, the many opportunities open to practical nurse graduates are reviewed. There is a little too much emphasis on the personal problems of the main character instead of on the training itself; however, this does show that the demands of everyday life need not stand in the way of a practical nursing career. It should be emphasized that the training is given by professional people and not by other practical nurses. When accompanied by appropriate written material or when introduced by someone who is familiar with the field of practical nursing, this will be a valuable film in recruitment and could be shown to women's clubs, PTA groups, and high school students.

Good Health Practices: Part II: 16 mm., color, sound, showing time 10 minutes. Produced in 1953 by and procurable on purchase ($90) from Avis Films, Inc., 904 E. Palm Ave., Burbank, Calif.

The purpose of this film is to instruct primary and elementary grade children in basic good health practices in regard to teeth, eyes, ears, nose, and posture. Judy and Jim's good health practices are portrayed in the course of a vacation day spent at the beach and at home. Before going to the beach, Judy pays a routine visit to her dentist, who confirms the results of her good dental practices. At the beach, the dependence upon mouth, eyes, ears, and nose for enjoyment of the simplest pleasures is shown. Later, at home, the children continue their good health practices while watching television, studying, eating, and going to bed.

Mistaken impressions and, at times, even incorrect ones are given. For example, blowing the nose one side at a time is recommended in the film, and the old fallacy that carrots are good for the eyes is presented. The photography is well done. The over-all ideas are good; however, the lack of medical and health consultation is evident. Even though many of the concepts may be right, the film is misleading because of this lack of consultation.

Drug Addiction: A Medical Hazard: 16 mm., color, sound, showing time 29 minutes. Prepared by Hon. H. J. Anslinger, Commissioner of Narcotics, Washington, D. C., and Dr. John C. Krantz Jr., University of Maryland School of Medicine, Baltimore. Produced in 1955 by Stark Films. Procurable on loan from Winthrop-Stearns, Inc., 1450 Broadway, New York 18.

This film begins with a lecture by Commissioner of Narcotics Harry J. Anslinger. He emphasizes the fact that narcotic drug addiction is many times more frequent in the medical and paramedical professions than in any other group. The greater part of this dramatic presentation portrays the life of a young physician who becomes an addict. The case history is taken from Mr. Anslinger's files. The signs and symptoms in the onset and course of addiction are not explained in an accepted medical frame of reference. One of the main points about drug addiction, namely, the fact that the addict generally has a psychogenic defect, is not mentioned. The film has a number of good points and carries a definite lesson; however, it should be shown to students in informal gatherings such as fraternity meetings rather than as a formal part of instruction in medical school.

Radioisotopes: Their Application to Humans as Tracer Studies and for Therapeutic Use: 16 mm., color, sound, 25 minutes. Produced in 1953 by and procurable on purchase ($335) or rental ($25) from Medical Film Guild, Ltd., 506 W. 57th St., New York 19.

This film gives a comprehensive review of up-to-date practices in the use of radioisotopes in a visually pertinent fashion. Tracer studies and therapeutic methods of application directly to the patient show the use of radioactive iodine, sodium, iron, calcium, lanthanum, strontium, cobalt, phosphorus, gold, and the neutron capture therapy involving boron for treatment of brain tumors. The film shows actual photographs of the techniques employed in administering these substances. It does not emphasize the methods used for protecting personnel. Neither does it make clear certain fundamental distinctions such as the distinction between gamma and beta radiation; however, it is a good over-all view of the subject, and the demonstration of techniques is well done. It will give the uninitiated general practitioner a graphic idea of what can be done and is being done with radioisotopes in clinical medicine.

NEW FILMS ADDED TO A. M. A. MOTION PICTURE LIBRARY

William Harvey and the Circulation of the Blood: 16 mm., black and white, silent, showing time 48 minutes. Produced in 1928 by the Royal College of Physicians, London. Procurable on loan (service charge $3) from Committee on Motion Pictures and Medical Television, American Medical Association, 535 N. Dearborn St., Chicago 10.

This film was prepared on the occasion of the 300th anniversary of the publication of "Exercitatio Anatomica de Motu Cordis et Sanguinis." The numerous essential procedures are carried out whereby Harvey convinced himself that the blood moves through the body in a circular manner rather than by surging to and fro. The procedures illustrated involve demonstrations on dissected human material, on living animals, and in the normal human living subject. The diversity of animals used would make it expensive to duplicate these experiments as lecture demonstrations, and the careful lighting, choice of human subjects, and the closeup views afforded by the camera make the human demonstrations superior to what would be afforded in ordinary lecture demonstrations. The emphasis throughout is on the actual text of Willis' translation of Harvey's book and on the anatomic and physiological material. This film is of special interest to students of medicine and to interns in that it demonstrates how much can be done with careful observation and very little apparatus. The archaic style of Willis' translation will make this film hard for some to follow; however, it could be seen profitably by every medical student at some time in his career. It should be shown to classes in physiology in the freshman or second year of medicine and again in the clinical years. The film will also be of value to those interested in the history of medicine.

Videclinic: Mind and Medicine: 16 mm., black and white, sound, showing time 46 minutes. Produced in 1955 by the Smith, Kline & French Medical Television Unit, in cooperation with the American Psychiatric Association and the American Medical Association. Procurable on loan (service charge $3) from Committee on Motion Pictures and Medical Television, American Medical Association, 535 N. Dearborn St., Chicago 10.

This film is a Kinescope of a program originally produced for closed-circuit television that outlines the problem of mental illness and the latest weapons developed to fight it. The research aspects of mental illness, including the use of lysergic acid to produce symptoms in normal and abnormal people for study purposes, are covered first. Next is shown the dramatic new uses of drugs in the treatment of mental disease, and finally there is a report on the "open ward" system and "therapeutic communities" directly from Belgium and England. This film is recommended for medical society and hospital staff meetings.

The Doctor Examines Your Heart: 16 mm., black and white (cleared for television), sound, showing time 11 minutes. Produced in 1955 with the cooperation of the American Heart Association by Bray Studios, Inc., New York. Procurable on loan (service charge $2) from Committee on Motion Pictures and Medical Television, American Medical Association, 535 N. Dearborn St., Chicago 10.

This film demonstrates the methods used by the physician in examining the heart and includes medical history, percussion to determine heart size, listening to the heartbeat with a stethoscope, determination of blood pressure and pulse rate, fluoroscopic examination, and use of the electrocardiogram. The purpose of the film is to show that, while the heart is the strongest organ of the body, it requires, like all mechanisms, a checkup in order to deal with inherent or developing irregularities. Logically, one should "service" the heart as one services an automobile or any mechanism that is in constant use. This interesting and attractive film is recommended for the general public. It will be useful to physicians who are called upon to speak on this subject to service clubs and can also be used in high school health education classes.

The Physiology of Reproduction in the Rat: 16 mm., color, sound, showing time 19 minutes. Prepared by Richard J. Blandau, M.D., and Anthony Canedo, University of Washington, Seattle. Produced in 1955 by the Department of Medical Illustration, University of Washington, supported in part by a grant from the Ortho Research Foundation. Procurable on loan (service charge $3) from Committee on Motion Pictures and Medical Television, American Medical Association, 535 N. Dearborn St., Chicago 10.

This film attempts to show the complete external and internal changes that may be observed during the reproductive cycle in the rat, including various reproductive phenomena such as running, mating behavior, and related ear quiver. An animated sequence is used to illustrate the significance of the cyclic changes observed in the vaginal smear. The opening scenes of the film contrast the behavior of the female rat during the period of estrus with her behavior between periods. The external behavior of both male and female during mating is well shown, and the time relations of the estrus cycle are set forth especially well. The sequences showing the changes in the external and internal genitalia of the female during estrus are good. A dramatic moment is shown when the ovum that is discharged by the ovary is seen to enter the oviduct. After that, time-elapse photography shows the penetration of the ovum by the spermatozoa. These pictures show modern microscopic and photographic techniques at their best and are at once attractive because of the use of color and instructive because of the careful planning and editing. The narration is good. This film deserves the highest praise and can be shown to nurses and medical students as a part of their courses in physiology. Physicians will be interested in seeing it as it shows the latest in photography and microscopy. Instructors in college classes in zoology, genetics, or physiology will welcome the film as a rather complete presentation of the essence of reproductive physiology.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Studies of the Physiology of the Dumping Syndrome. K. E. Roberts, H. T. Randall, H. N. Bane and others. New York J. Med. 55:2897-2902 (Oct. 15) 1955 [New York].

Sixty experiments were carried out on 34 patients who had undergone gastrectomy to study the alterations in blood volume, extracellular fluid, and blood pressure after the ingestion of various foodstuffs consisting of hypertonic glucose, carbohydrates given in the form of corn starch or cooked potatoes, protein given in the form of beefsteak or as a powdered commercial preparation, and fat given in the form of vegetable oil or a commercial homogenized preparation. The patients showed at least three major metabolic defects, i. e., severe dumping symptoms, inadequate caloric intake, and defective fat and nitrogen absorption. The experiments indicated that the dumping symptoms are associated with an acute decrease in circulating blood volume and extracellular fluid, a decrease in blood pressure, and electrocardiographic changes consistent with myocardial ischemia. It has been postulated that the acute alterations in blood volume and electrocardiographic changes are triggered by rapid enzymatic hydrolysis of foodstuffs within the jejunal lumen and a subsequent breakdown of larger molecular particles into their smaller molecular components with a corresponding increase in osmolarity. As a result of the increased osmolarity, extracellular fluid is shifted into the jejunal lumen in an attempt to maintain the jejunal contents isotonic with the plasma. Carbohydrate substances were observed to have a greater effect than protein in triggering this chain of reactions. A dietary regimen has been proposed that is based on these findings and consists essentially of a high-protein, low-carbohydrate diet given at frequent feeding intervals. Preliminary results indicate that patients placed on this diet gained weight and showed symptomatic improvement.

Peptic Ulcer in Laennec's Cirrhosis. W. P. Swisher, L. A. Baker and H. D. Bennett. Am. J. Digest. Dis. 22:291-294 (Oct.) 1955 [Ft. Wayne, Ind.].

Of 417 patients with Laennec's cirrhosis, 58, or 13.9%, had peptic ulcer in addition to their liver disease. Fifty-one had duodenal ulcers, and seven patients had gastric ulcers. X-ray evidence of duodenal ulcer was found in 47 cases. Postmortem examination revealed one healed duodenal ulcer and three active duodenal ulcers not demonstrated by x-ray studies. Gastric ulcer was diagnosed in six patients by roentgen examination and in one patient at autopsy. The presence of peptic ulcers in 13.9% of patients with Laennec's cirrhosis is far above the expected incidence of peptic ulcers in hospitalized patients. Sixteen or 28% of the 58 patients with hepatic cirrhosis and peptic ulcer were hospitalized because of hemorrhage from the ulcer. The physiological and pathological states present in cirrhosis may increase the predilection toward peptic ulceration. Possible predisposing factors are: absence or relative absence of neutralizing bile salts from the gastrointestinal tract, stimulatory effect of alcohol on hydrochloric acid secretion, direct inflammatory effects of alcohol on gastric and duodenal mucosa, increase of portal pressure and resultant venous stasis in bowel, malnutrition and altered serum proteins, impairment of the steroid metabolism, and finally psychosomatic phenomena. A combination of several such factors probably accounts for the increased incidence of peptic ulcer. Most important seem to be the direct stimulating and irritant action of alcohol, absence of neutralizing food, and perhaps a decrease in flow of bile salts and underlying psychiatric disturbances. No evidence was found in this series to incriminate portal hypertension, hypoproteinemia, or hyperbilirubinemia. This study indicates that one cannot assume that hematemesis or melena in a patient with Laennec's cirrhosis is always due to a ruptured esophageal varix. The common coincidental finding of peptic ulcer with Laennec's cirrhosis makes it imperative that an accurate diagnosis be made as soon as possible in any patient with Laennec's cirrhosis who is bleeding from the gastrointestinal tract.

Relations of Type of Tumor and Localization of Bronchial Carcinoma to Pulmonary Ventilation and Changes in Their Relationship by Exogenous Influences (Chronic Bronchitis, Pneumonia, Smoking). B. Löhr and A. Wagner. Arch. klin. Chir. 280:592-608 (No. 6) 1955 (In German) [Berlin Germany].

The clinical data of 435 patients with bronchial carcinoma admitted to the surgical clinic of the University of Heidelberg, Germany, between 1947 and 1953, were studied in an attempt to draw conclusions from them concerning the origin of the disease. Because of the many factors involved and of the possibility of their combinations, the authors searched for unequivocal and constant features. Localization of tumor and type of tumor were observed as being suitable in this regard. Comparison of the localization of the tumors with pulmonary ventilation showed a parallelism in that, in 51% of the patients, the right lung and its bronchial branches were involved by carcinoma, and in 49% the left lung was affected, while the ventilation of the right and the left lung took place in a ratio of about 54 to 46. The percentage distribution of tumors thus corresponded with the respective sections of the lung. This correspondence between involvement by tumor and ventilation was observed likewise with regard to pulmonary lobes and various sections of the bronchial tree. It was therefore concluded that a cause and effect relationship exists between ventilation (i. e., inhalation of carcinogenic noxae) and involvement by tumor. Furthermore, it was found that, with the same percentage of involvement by tumor, the squamous epithelium carcinoma occurred more frequently in the central portions of the bronchial tree while the small cell carcinoma occurred more frequently in the peripheral portions of the bronchial tree. It was assumed that this relationship between localization of tumor and type of tumor would be changed with respect to the percentage of involvement by tumor as soon as exogenous stimuli of sufficient intensity occurred. Chronic bronchitis, pneumonia, and smoking were considered as such stimuli, and their effect on the relationship between localization and type of tumor was studied. For each of these three groups of patients a special predilection with regard to localization of the tumor was found, and predominance of squamous cell carcinoma was definitely shown in the group of patients with bronchitis and in patients who smoked. These findings confirmed the concept that the development of bronchial carcinoma depends essentially on exogenous stimuli; it was shown simultaneously that it can no longer be denied that bronchitis, smoking, and pneumonia play a part in its causation.

Insensitivity to Vitamin D Developing During the Treatment of Postoperative Tetany: Its Specificity as Regards the Form of Vitamin D Taken. C. E. Dent, C. M. Harper, M. E. Morgans and others. Lancet 2:687-690 (Oct. 1) 1955 [London, England].

The authors present the histories of four patients in whom, after the accidental surgical removal of the parathyroids during operations on the thyroid, there developed chronic hypocalcemic

---

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1946 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

tetany. All showed a greatly increasing insensitivity to the hypercalcemic action of calciferol, even though the patients had been free of symptoms and normocalcemic before on smaller doses. When, instead of calciferol, the same or smaller doses of dihydrotachysterol (A. T. 10) were given to three of these patients, or of vitamin D_3 to the fourth patient, the symptoms of tetany were rapidly relieved and the plasma calcium level rose rapidly to normal. All of the patients are now well maintained on relatively small doses of the substituted vitamin D preparations. In two patients the change from calciferol to dihydrotachysterol and from calciferol to vitamin D_3 was carried out under metabolic control. This showed that the change of vitamin D preparations coincided with the onset of normal vitamin D action. It seems probable that, in the future treament of postoperative tetany, it will become necessary to change from one form of vitamin D to another. This curious phenomenon is likely to have some bearing also on the pathogenesis and treatment of those various forms of bone disease that include so-called "resistance to vitamin D" as one of their features.

A Thyroid Blocking Agent as a Cause of Endemic Goitre in Tasmania: Preliminary Communication. F. W. Clements. M. J. Australia **2**:369-371 (Sept. 3) 1955 [Sydney, Australia].

The results of two goiter surveys in Tasmania at an interval of five years and subsequent investigations strongly support the hypothesis that a significant amount of the endemic goiter in that state is due to the blocking effect of a substance or substances present in the diet of children. After a goiter survey in 1949 of some 8,000 school children, which confirmed that most of the island was goitrous, tablets containing 10 mg. of potassium iodide were distributed weekly to school children in Tasmania for the next five years. The second survey in 1954 showed a fall in the incidence of goiter in children of all ages in two districts, and in older girls in most districts; but there was a considerable rise in incidence in the younger children in most of the island, and the rate for boys equaled that for girls. This increase had occurred even in those schools where the distribution of iodine tablets was regular and complete. In the five years between the surveys, there was a considerable increase in milk consumption by children in Tasmania, owing to the introduction of the Commonwealth government's free milk scheme. To meet the demand for extra milk, a number of changes were made in dairy practice, including a great increase in the production of a forage crop, chou-mollier (thousand-headed kale), which is one of the Brassicæ. In view of the discovery by Astwood and his co-workers that some Brassicæ contain an antithyroid substance—namely, *l*-5-vinyl 2-thiooazolidone—it was decided to test for antithyroid activity milk, and extracts from milk, from cows fed chou-mollier and other Brassicæ. Tests were made with radioactive iodine, I^{131}. Two girls who drank the milk from cows fed chou-mollier had definite interference with the uptake of the I^{131} compared with the uptake of three other girls. A pair of identical twins was used, one in each group. Similar results were obtained in tests on other subjects with whole and skimmed milk, and to a lesser extent with various extracts. The investigation of milk from cows fed various Brassicæ is proceeding, and attempts are being made to obtain the antithyroid substance in a highly concentrated or pure form.

Tonsillitis and Splenomegaly. P. G. Cronk and P. G. I. Stovin. J. Roy. Army M. Corps **101**:231-234 (July) 1955 [London, England].

Nineteen of 185 British soldiers and their wives admitted to a hospital in the Suez Canal Zone with tonsillitis were found to have degrees of splenomegaly easily detected by routine palpation. Only in five cases was there adenopathy apart from tonsillar adenitis. Seven of the patients had had jaundice in the past, and one had had malaria. The clinical picture of tonsillitis, splenomegaly, and in a few cases cervical lymphadenopathy is rather suggestive of the anginose type of glandular fever, but white blood cell counts, blood film examinations, and repeated Paul-Bunnell tests ruled out glandular fever. The authors suggest that the probable connection between the tonsillitis and the splenic enlargement is the removal of neutralization of absorbed streptococcic toxins by the spleen as the main organ in the reticuloendothelial system. They think that this may occur more frequently than is realized in tonsillitis, though a search of the literature has failed to reveal any references to this combination of signs.

Painful Non-Arthritic Disturbances of the Hand and Wrist. E. C. Toone Jr. and J. Kawchak. Virginia M. Month. **82**:441-443 (Oct.) 1955 [Richmond, Va.].

Many lesions besides arthritis may affect structures near the joints. The authors discuss three painful syndromes of the hand and wrist, which are rather frequent but are often not diagnosed for months or years. Each may be treated effectively with relatively minor surgical procedures. The first is DeQuervain's disease, which is a painful syndrome resulting from the thickening and stenosing of the tendon sheaths of the abductor pollicis longus and extensor pollicis brevis at the ligament of the styloid process of the wrist. Activities such as typewriting, knitting, fly casting, golfing, piano playing, and work on grinding and buffing machines, which place these tendons under stress, predispose to this condition. The predominant early symptom is pain over the radial styloid process, which may radiate down into the thumb or up into the forearm. The discomfort is usually constant. The Finkelstein test, which is almost pathognomonic, is carried out by abducting the thumb across the palm, flexing the fingers over the thumb, and then sharply deviating the hand to the ulnar side. When the test is positive, an excruciating pain develops at the styloid process of the radius. Surgical treatment is simple and effective. The dorsal carpal ligament and the common sheath of the abductor pollicis longus and the extensor pollicis brevis are incised under local anesthesia. If the thickening is marked, the portions forming the roof of the osteofibrous canal are excised partially or completely. The carpal-tunnel syndrome results from compression of the median nerve by the transverse carpal ligament of the wrist and the contents of the carpal tunnel. Sensory symptoms constitute the earliest clinical feature and are limited to the distribution of the median nerve. At first, numbness may be present only during paroxysms of pain, but later a permanent hypalgesia and hypesthesia may be present. If the involved wrist is held in flexion for 60 seconds, there may be rather marked accentuation of symptoms. Also, the sensory changes may be accentuated by percussion over the median nerve. Surgical treatment consists of sectioning the transverse carpal ligament, thus decompressing the carpal tunnel. A successful operation is usually followed by prompt disappearance of pain and paresthesias and restoration of normal motor function. The trigger-finger syndrome results from a stenosing tendovaginitis of the digital flexor tendons of the thumb or lesser fingers usually at the metacarpophalangeal or the proximal interphalangeal joint. A number of these patients will improve with immobilization. If no improvement follows three weeks' conservative treatment, the tendon sheath constriction can be released by a simple surgical procedure. None of these conditions responds to medication usually employed in treating arthritic lesions.

Insulin Resistance and Scarce Insulin Sensitivity in Pancreatic Diabetes: One Clinical Case. T. Chiarioni and E. Nardi. Gior. clin. med. **36**:1091-1114 (Aug.) 1955 (In Italian) [Bologna, Italy].

Resistance or low sensitivity to insulin in patients with pancreatic diabetes may be due to infectious disease and febrile episodes; formation of anti-insulin antibodies; markedly decreased hepatic functional activity; excess insulinasic activity; anterior hyperpituitarism; hyperadrenalism; or hypertonia of the sympathetic nervous system. The authors report the case of a 44-year-old man whose sugar level when first seen was 190 mg. per 100 cc. and who was not benefited by diet and insulin. After eight months the blood sugar level was 240 mg. per 100 cc. He was then hospitalized, and, despite a diet without carbohydrates and insulin administration, the glycosuria and acetonuria remained extremely high. A dose of 120 units of insulin and a diet containing 60 gm. of carbohydrates daily caused, after 20 days, the disappearance of the ketosis, but the glycosuria and the subjective symptoms remained unchanged. Comparing the quantity of carbohydrates ingested and that lost in the urine, it was evident that the ratio between the grams of carbohydrates utilized and the units of insulin administered was significantly below the ratio that is usually found in patients with uncomplicated diabetes. A cycle of 12 x-ray irradiations to the hypophysis (130 r per session) on alternating days and intramuscular administration of 5 mg. of testosterone caused the glycosuria to disappear, and the daily amount of insulin could be reduced. The patient was discharged and instructed to eat a diet like the one at the hospital and to continue with the same dose of insulin. This was a case of pancreatic diabetes aggravated by the patient's low sensitivity to the action of insulin. This aspect of the disease did not seem attributable to inactivation or destruction of insulin but rather to factors inherent in the neuroendocrine constitution of the patient, in particular to a moderate anterior hyperpituitarism and, even more, to hypercorticalism. A lability of the patient's neurovegetative tonus with a tendency to episodes of hypertonia of the sympathetic nervous system may have been a collateral factor.

A New Corticosteroid: Metacortandracin. L. de Gennes and B. Mathieu de Fossey. Presse méd. 63:1270-1273 (Oct. 1) 1955 (In French) [Paris, France].

Metacortandracin (prednisone) has an anti-inflammatory action greater than that of cortisone; the amount has been reported to be 2.5 to 4.6 times greater, depending on both author and patient. The drug has given good results in arthritis, ankylosing spondylitis, acute gout, arthrosis, rheumatic fever, asthma, disseminated lupus erythematosus, periarteritis nodosa, some of the milder dermatoses, and scleroderma. Fair results have been obtained in acute leukemia, lymphosarcoma, and lipid nephrosis. Metacortandracin is inert with respect to the sodium ion and therefore causes no retention of either sodium or water. Patients receiving this hormone do not have to be put on a low-sodium diet. Most authors agree that potassium supplements are not necessary either but that a diet rich in proteins will supply enough of this element to replace whatever small amount is depleted by the drug. Metacortandracin increases the amount of hydrochloric acid in the gastric juice more than does hydrocortisone, but it has little effect on gastric juice volume and none on uropepsin secretion. The hormone has some catabolic effect on tissue proteins, but this disappears after the first few days of treatment. It stimulates erythropoiesis and causes an increase in hemoglobin. It has the usual side-effects of hypercorticalism and psychic disturbance. In general, it appears that this new steroid can replace cortisone and hydrocortisone, except in the treatment of adrenal cortical hypofunction.

Treatment of Recurring Pyelonephritis. E. M. Blegen and H. N. Haugen. Tidsskr. norske lægefor. 75:603-606 (Sept. 1) 1955 (In Norwegian) [Oslo, Norway].

The importance is stressed of recognizing the origin of symptoms of urinary infection, such as frequent, painful micturition, fever, and pyuria, which in a large proportion of cases is a relapsing pyelonephritis. Decisive diagnosis depends on careful microscopic examination of the urine. In the intervals between relapses there may be no symptoms. Recurrence means flare-up of a surface process while at the same time a deeper process in the kidneys is active. Since late in 1952 the authors have treated recurring pyelonephritis with a combination of agents that exert their effect on both the surface processes and the deeper processes. Sulfonamide and sodium bicarbonate are given alternately with a mandelic acid preparation and ammonium chloride for two weeks' courses, respectively, and a total of eight weeks' treatment. Alkaline ash and acid ash diets are applied during the respective courses. In some cases 0.5 gm. of streptomycin was administered twice daily for five days simultaneously with sulfonamides. Up to the end of 1954, 30 patients (3 men, 27 women) were treated. Follow-up of 20 of these from 2 to 28 months after treatment ended showed 17 to be free from symptoms, with normal urine. There were no complications. Complete recovery cannot be expected in all cases: there may be a chronic glomerulonephritis complicated with pyelonephritis or the pyelonephritis may be so advanced that irreversible changes have developed in the kidneys.

Renal Biopsy in Glomerulonephritis and Nephrotic Syndrome. H. Gormsen, T. Hilden, P. Iversen and F. Raaschou. Nord. med. 54:1341-1348 (Sept. 1) 1955 (In Danish) [Stockholm, Sweden].

With regard to the purely practical value of renal biopsy in the diagnosis, differential diagnosis, prognosis, and treatment of glomerulonephritis, the authors conclude that the method, provided that the biopsy is ample enough to be considered representative, definitely establishes whether the clinical diagnosis is correct, definitely evaluates the gravity of a glomerulonephritis, estimates duration only fairly well, and determines whether there is an acute glomerulonephritis or an acute flare-up of a previously existing chronic glomerulonephritis, which is important in deciding the duration of confinement to bed. In patients with nephrotic syndrome, renal biopsies can give the etiological diagnosis. In cases of oligoanuria of vague etiology, the results of biopsy can be decisive in determining whether hemodialysis should be carried out. It is often impossible on the basis of clinical criteria alone to determine whether an oligoanuria depends on a grave acute or chronic glomerulonephritis, in which case hemodialysis must presumably be regarded as useless, or on an acute tubulointerstitial nephritis with intact glomeruli, in which case hemodialysis will sometimes be indicated.

Oral Hydrocortisone Therapy in Rheumatoid Arthritis: An Appraisal of General Results of Prolonged Administration. E. W. Boland. Ann. Rheumat. Dis. 14:232-237 (Sept.) 1955 [London, England].

Results of prolonged oral hydrocortisone therapy in 150 consecutive patients with active peripheral rheumatoid arthritis were analyzed. Treatment was continued for from 9 to 36 months. At the time of analysis, treatment had been discontinued in 24 patients for the following reasons: insufficient clinical response in 4, major complications in 2, complications unrelated to hydrocortisone in one, death from extraneous causes in 5, and remission in 12. The chief factors that influenced the success of therapy were the severity or activity of the disease and the duration of arthritis before treatment. At analysis, improvement was graded as adequate in 36% of patients with severe disease, 57% with moderately severe disease, and 88% with moderate disease. Results were more favorable when the arthritis was of relatively recent origin; the crucial duration was about two years, and thereafter as duration lengthened the proportion of adequate response lessened. As time went on, fewer patients showed adequate improvement. The disease was restrained satisfactorily in 72% at 6 months and in 59% at 18 months. Fifty of the 150 patients showed evidence of progression during the observation period. Although hydrocortisone is a valuable agent in the management of selected cases of rheumatoid arthritis, it is far from an ideal suppressive agent. Like cortisone, it has many shortcomings, chief among which are the hormonal side-effects, especially when dosage requirements are large; the tendency to aggravate certain coexisting pathological conditions; the development of unresponsiveness in some patients after prolonged administration; and the failure to prevent disease progression in an appreciable percentage of cases.

Acute Hemolytic Anemia in Infectious Mononucleosis: A Report of a New Case and a Review of the Literature. L. J. Kirkham. J. Iowa M. Soc. 45:525-530 (Oct.) 1955 [Des Moines, Iowa].

Eleven cases of infectious mononucleosis associated with acute hemolytic anemia were collected from the literature. A new case is described in an 8-year-old girl who had been ill for a week with malaise and fever. At the onset she had three or four erythematous papules scattered over her body, but they cleared completely within three days. She also complained of some mild pain in her right shoulder, and of mild upper abdominal pain. She was given 500 mg. of tetracycline (Achromycin), and on the evening of the same day she voided dark brown urine, and was admitted to the hospital. She voided similarly colored urine for the next four days. The patient was running a temperature of 103 F (39.4 C) and had a mild acute pharyngitis and definitely enlarged lymph nodes in all cervical areas and in the axillary, epitrochlear, and inguinal regions. The spleen was palpable 3 cm. below the costal margin but was not tender. The liver was tender and was thought to be slightly enlarged. The blood cell count showed 3,890,000 per cubic millimeter red blood corpuscles, 12,000 per cubic millimeter white blood corpuscles, 86% lymphocytes, and 11% hemoglobin on the first day after admission, and 4,060,000 per cubic millimeter red blood corpuscles, 18,500 per cubic millimeter white blood corpuscles, 95% lymphocytes, and 11.5% hemoglobin on the fourth day after admission. Most of the lymphocytes observed in the patient's blood smear were considered typical of infectious mononucleosis. The treatment she received was essentially symptomatic, and in addition bed rest and 1 gm. of chloramphenicol (Chloromycetin) daily for five days. The patient was thought to be the first with infectious mononucleosis in whom hemoglobinuria occurred. She made a complete recovery. Although several of the previously reported 11 cases failed to satisfy the criteria completely, it is felt that hemolytic anemia unquestionably does occur in infectious mononucleosis and, further, that it is increasing in frequency. Most of these patients did not require special treatment, but some responded well to the steroid hormones, and one recovered promptly after splenectomy without a therapeutic trial of hormones. The mechanism of the hemolysis has not been clarified very much by the immunologic studies that were done. The hemoglobinuria that occurred in the author's case strongly suggested an intravascular hemolytic process, while the rapid response to splenectomy seen in another case supported the concept of hypersplenism and, therefore, an extravascular hemolytic process. Another concept is that of the production of hemolytic immune bodies, which was supported by the response of several patients to steroid hormones and also by the author's patient with hemoglobinuria. It seems that the possible mechanisms of hemolysis may differ from patient to patient, depending on the patient's previous exposure to antigenic agents. The increased incidence of hemolysis associated with infectious mononucleosis coincided with the advent of potent antibiotic agents, and, although more studies are required before antibiotics can be pointed out as the cause, it is felt that they may be to blame.

Variola in France in 1955: Epidemiology and Prophylaxis. B. Le Bourdellès, M. Berger, M. Rodallec and others. Presse méd. **63:**1247-1248 (Sept. 24) 1955 (In French) [Paris, France].

France has had eight epidemics of variola since the second world war. Three of the first five were known to have originated from carriers coming from North Africa, but the last three were brought from the Orient. The 1955 epidemic in Brittany was started by a French soldier on leave from the war in Indochina; it comprised 95 frank cases, with 20 deaths, and 11 abortive cases. The first cases were difficult to diagnose because of the protean nature of the disease developing in a semi-immunized population. There were many atypical and uneruptive forms. The extreme contagibility of the disease testified to the especial virulence of the far eastern virus. Importation of this virus is likely to become increased, by virtue of the enormous expansion of air travel. Prophylactic measures should, therefore, be practiced with greater strictness.

Systemic Blastomycosis: Report of a Case. V. H. Knight Jr. and W. W. Wilson. J. Florida M. A. **42:**275-277 (Oct.) 1955 [Jacksonville, Fla.].

The authors present the history of a 56-year-old man, who one year previously had noted the onset of exertional dyspnea, a mild nonproductive cough, and a wart-like growth on the right cheek. Later this skin lesion ulcerated, and a biopsy revealed double contoured bodies compatible with blastomycosis. A cutaneous lesion developed also on the wrist. Roentgen examination of the chest revealed a diffuse, bilateral, granular and nodular infiltration. Smears made from the skin lesion and the sputum showed Blastomyces dermatitidis, and this finding was confirmed by mycologic culture. Despite abnormalities in the hepatic and renal functions, the authors resorted to treatment with stilbamidine. The recent introduction of 2-hydroxystilbamidine is an advantage, as it is less influenced by sunlight than is stilbamidine. The drug is administered intravenously, usually in doses of 150 mg. dissolved in 500 ml. of 5% glucose. The drug is administered daily, until a total dose of 3.5 to 4.6 gm. is reached. The man whose history is presented received a total of 4.2 gm. of stilbamidine in a period of 30 days. He showed slow but progressive improvement. Nine months after the completion of treatment he felt well, except for a mild disturbance in the sensory portion of the trigeminal nerve, which, however, has slightly improved since its first appearance three months after treatment. This case illustrates the effectiveness of stilbamidine in a highly fatal disease.

Nephritis Without Albuminuria (Acute Postinfectious Angiopathy). G. Czoniczer and T. Zsótér. Ztschr. ges. inn. Med. **10:**748-752 (Aug. 1) 1955 (In German) [Leipzig, Germany].

Of the four classical symptoms of diffuse glomerulonephritis (albuminuria, hematuria, edema, and hypertension), albuminuria is generally regarded as the most constant. Some authorities regard the diagnosis of acute nephritis as doubtful if albuminuria is absent. Among 30 patients with acute nephritis observed by the authors in the course of three and one-half years, there were 4 in whom albuminuria was absent. These patients ranged in age from 14 to 31 years. All four had had another disease from 3 to 14 days before the onset of the nephritis; one had had a "cold," two tonsillitis, and one sore throat. Edema and hypertension were present in all four, hypertension always persisting for from two to three weeks or even longer. Edema was usually of moderate degree and seemed limited to the face. In one patient the edema was latent, becoming apparent only as the result of treatment, which resulted in diuresis and loss of weight. Fasting always counteracted the edema in the course of about one week. That these patients actually had nephritis was demonstrated by the characteristic forms of hypertension and edema and by the fact that, in the later course of the disease, albumin always appeared in the urine, at least in small amounts. The authors suggest that this form, in contradistinction to the classical form of glomerulonephritis, could be designated as "acute postinfectious angiopathy," because they feel that vascular changes are the chief characteristic of this form of nephritis.

SURGERY

Considerations in the Surgical Treatment of Ventricular Septal Defects. E. B. Kay, H. A. Zimmerman and F. S. Cross. J. Thoracic Surg. **30:**452-468 (Oct.) 1955 [St. Louis].

Patent ductus arteriosus, atrial septal defects, and ventricular septal defects all represent essentially the same type of physiological lesion, that is, one with left to right shunting of blood with overloading of the pulmonary circulation. Surgical correction in each of these defects may be deferred until the optimum time arrives for intervention, unless the patient is getting into severe difficulties. Severe clinical symptoms and cardiographic and x-ray changes in a patient with a ventricular septal defect, however, should be taken as an indication for early cardiac catheterization and, if the intraventricular and pulmonary pressures are found to be elevated, surgical repair of the defect should be seriously considered. The repair must be made before the vascular changes caused by pulmonary hypertension become irreversible if the patient is to be benefited. Increasing pulmonary and right ventricular pressures add to the risk of surgical intervention, but the dangers of waiting should always be weighed against the risk of the operation. All the factors, including the age of the patient, the period during which the elevation of the pressures has existed, the size of the heart, the degree of pulmonary vascularization (by x-ray), and the pulmonary reserve, must be taken into consideration. Six patients have been operated on by the authors in the last two years, two by closed techniques and four through an open cardiotomy. The first closed-technique operation, in which a ventricular septal defect was repaired by a suture method in a 20-year-old white girl, was successful, and the patient is now able to lead a normal life. A second closed-technique operation, performed on a 5-year-old girl, failed when fatal ventricular fibrillation developed. Cross circulation was employed in three of the open cardiotomy operations, with one successful closure and two deaths; in the other, no suitable donor was available, and an attempt was made to use a pump and a reservoir of oxygenated blood instead. Ventricular fibrillation developed, however, as soon as the ascending aorta was occluded, and a normal rate could not be restored. The many inherent difficulties encountered in attempts to repair ventricular septal defects by the open techniques now available make the continued investigation of closed techniques advisable. The principle of reconstituting the membranous ventricular septum by inversion and approximation of the pliable cardiac wall between the right atrium and aorta to the apical portion of the defect appears promising and is being utilized in all the closed techniques now being studied.

Experiences with Surgical Repair of Atrial Septal Defects. E. Watkins Jr. and R. E. Gross. J. Thoracic Surg. 30:469-491 (Oct.) 1955 [St. Louis].

The atrial septal defects found in 43 patients operated on by the authors, though varying greatly in size and shape, tended to fall into the following five general categories, according to their location in the septum: (1) the common atrium defect (2 cases); (2) the so-called ostium primum defect, which the authors prefer to classify as an endocardial cushion defect, because it is related not only to inadequate fusion of the primitive atrial septum with the endocardial cushions (the anlage of the mitral and tricuspid valve rings) but also to incorrect maturation of the endocardial cushions themselves (4 cases); (3) the inferior defect, which must be distinguished from the endocardial cushion defect (5 cases); (4) the midatrial marginal defect, which was the commonest type encountered (28 cases); and (5) the superior marginal defect (15 cases). The fact that serious conduction disturbances and death may occur when the atrioventricular conduction bundle is traumatized or cut makes the identification and avoidance of this specialized tissue a matter of vital importance. It will be found anterior to a line drawn between the valve of the coronary sinus and the central fibrous body—two landmarks within the atrial chamber that can be palpated at operation. Definition of the landmarks and connecting line is now performed routinely during the exploration of all atrial septal defects. The endocardial cushion defect may prove suitable for closure by external suture, but the associated valve deformity introduces serious problems after closure. The common atrium defect seems to require some kind of prosthesis or tissue graft to avoid atrial and valve-ring distortion. Defects in the other three categories, which are located along the posterior margin of the atrial septum, constituted 86% of those seen in these patients; they are best suited for closure by the external suture method. The atrial wall method is now reserved for use in malformations that cannot be closed by external suture, either because of their large size or because they are situated anteriorly in the septum. Defects lying near a caval orifice should be closed by sutures introduced into the heart through the left atrial wall to avoid constricting the caval orifices by suture. Postoperative management has sometimes been complicated by the appearance of transient left ventricular failure. A prophylactic regimen of fluid limitation is therefore applied to all patients during the immediate postoperative period, and digitalis and mercurial diuretics are given if failure develops. Arrhythmias are frequent during this period of failure. Six of the nine deaths that occurred among the first consecutive 22 patients were due to technical errors that experience has since shown to be avoidable. Deaths in the last 21 patients were limited to two patients with advanced pulmonary vascular obstruction and two with serious atrioventricular valve deformity. These conditions are now regarded as contraindications to valve closure by present methods. Clinical improvement in the surviving patients has been striking. All have reported increased exercise tolerance and relief of symptoms.

An Analysis of Fifty Patients Treated by Mitral Commissurotomy Five or More Years Ago. R. P. Glover, T. J. E. O'Neil and O. H. Janton. J. Thoracic Surg. 30:436-451 (Oct.) 1955 [St. Louis].

The first 50 consecutive patients in the authors' mitral commissurotomy series have been followed up, and the 41 survivors have been intensively studied in an attempt to ascertain their present subjective and objective status. All were operated on from five to six and a half years ago. Each of the 50 patients was suffering from some degree of functional incapacity; 20 had a definite history of rheumatic infection; 23 had a history of gross hemoptysis; 27 had had one or more bouts of congestive failure; and arterial emboli, from which a reasonable recovery had been made, had occurred in 6. Thirteen were in gross chronic congestive heart failure on admission to the hospital, and 19 were in permanent atrial fibrillation. Three patients died within the first postoperative month, and six died within the first three postoperative years. All the deaths occurred in patients with advanced stage 3 (progressively incapacitating) or stage 4 disease. Appraisal of the patient's subjectively reported clinical state and a correlation of the clinical findings, electrocardiographic tracings, teleroentgenograms, and catheterization data in each case warrant the conclusion that 30 (73%) of the survivors are in better condition and living a more nearly normal life than they were before the operation. The conservativeness of this estimate is shown by the fact that, according to their own and their family physician's appraisal of their present clinical status, 36 (88%) of the survivors are better now. No definitive conclusions concerning their present clinical status could be reached on the basis of their murmurs alone. Only 4 have a heart free from murmurs; 11 have lost all evidence of their original mitral diastolic murmur, but 14 now have mitral systolic murmurs of varying degrees that were not present before the operation. The best results from mitral commissurotomy are routinely obtained in patients with a pure murmur of mitral stenosis indicative of a small mitral orifice (cigarette size or less). Conclusive evidence of improvement does not regularly appear in the postoperative electrocardiograms, but electrocardiographic changes indicative of a definitive return to normal will be found in a considerable percentage of patients. Roentgenographic studies showed that, in 87% of these patients, the heart had remained at its preoperative size or had become smaller, whereas before the operation it was growing progressively larger. The functional state of the patients was paralleled and corroborated by all the cardiac catheterization data available. Valvular calcification was present before operation in 20 patients and in these the degree of improvement obtained, though satisfactory, was less than that obtained in those whose valves were free of calcium deposits. Eight patients showed definite evidence of rheumatic activity during the postoperative period. No evidence of restenosis has been observed in any of the surviving patients, nor was any present in the valves of those who died in the postoperative period. Only one patient had an operative embolus, and she has now completely recovered from her left hemiplegia, except for the finer motions of the hand. No postoperative emboli have occurred up to the present time. Commissurotomy has been of untold value to most of the patients in this series, and there is no reason to suppose that the improvement obtained will not continue.

Surgical Treatment of Coronary Insufficiency. J. N. Briggs and F. X. Byron. West. J. Surg. 63:559-561 (Sept.) 1955 [Portland, Ore.].

The authors present a history of the various attempts at myocardial revascularization, giving special attention to the three commonly used procedures: the cardiopericardiopexy of Thompson, the arterialization of the coronary sinus advocated by Beck, and Vineberg's internal mammary implantation. The authors favor the cardiopericardiopexy or pericardial poudrage of Thompson. It is technically simple, requiring little equipment and no specialized training. This operation utilizes all the available collaterals, the pericardiophrenic arteries, the internal mammary arteries, the inferior phrenic arteries, and the adjacent mediastinal vessels. Furthermore, this procedure has had the greatest clinical trial, and some of Thompson's patients have been followed for 14 years. The authors have used Thompson's method in eight cases. As regards the selection of patients for this treatment, they say that it should be used only after failure of medical treatment. The heart may be moderately enlarged, but patients in heart failure are not suitable candidates. There are no age limits, but there is more risk in younger patients. Operations should not be performed within three months of an infarct and preferably six months should have elapsed. Of the eight patients operated on by the authors, three have died, but only one of these was an operative death. It occurred on the sixth day after operation and was due to fresh infarction in a greatly narrowed coronary artery. This patient would not meet the present criteria for operation. The two late deaths were due to coronary infarction, but both patients had been improved by Thompson's criteria up until the time of death, 6 and 14 months after operation respectively.

Local Hypothermia of the Heart: Preliminary Report. D. Melina and C. Pollara. Gior. ital. chir. **11**:940-943 (Aug.) 1955 (In Italian) [Naples, Italy].

The authors' experiments with general hypothermia combined with a more pronounced local hypothermia of the heart were based on the fact that the "biological zero," i. e., the temperature limit at which point the specific functional activity of a cell ceases, of the myocardial tissue is much lower than that of the nervous tissues (30 to 24 C [86 to 75.2 F] according to the various zones). General hypothermia (rectal temperature of 28 C [82.4 F]) was rapidly induced in a group of dogs after they had been given deep Pentothal anesthesia. After the circulation was arrested by occlusion of the venae cavae, the azygos vein, the aorta, and the pulmonary artery, the heart was cooled directly by means of carbon dioxide, and its internal temperature, as measured with a regular thermometer after an atrial or ventricular cardiotomy, was lowered to 20 C (68 F). At this temperature, marked bradycardia (four to six pulsations per minute) was present. This method enabled the authors to interrupt the circulation for 30 minutes, during which time various surgical procedures were performed on the cavities of the heart. The authors state that the circulation can be interrupted in some cases for longer time (43 minutes in one dog) and that general hypothermia combined with more pronounced local hypothermia of the heart makes it possible not only to prolong the circulatory arrest but also to prevent the onset of a state of myocardial anoxia. Ventricular fibrillation, a much feared and often irreversible and fatal complication of general hypothermia, is also prevented.

Contralateral Pulmonary Metastases in Bronchial Cancer. A. Balmes and A. Thevenet. Presse méd. **63**:1297-1301 (Oct. 5) 1955 (In French) [Paris, France].

Five cases of contralateral pulmonary metastasis were noted in a series of 75 cases of bronchial cancer. A review of the literature showed that about 20% of bronchial cancers metastasize into the contralateral lung; only 10% are detectable radioclinically. Secondary cancer of the lung represents about 30% of cancer metastases in general. Recent figures show that the primary tumor is located in the bronchi in about 5% of cases. The circumstances of the clinical appearance of these metastases are of four types. 1. They may be noted at the time of initial examination revealing cancer or even before the primary tumor manifests itself. 2. They may be secondary metastases, i. e., manifesting themselves in the weeks following discovery of the initial lesion. In such cases, as in those of early metastases, the cancer has revealed itself late and is inoperable. 3. The metastases may appear late, after surgical treatment of the bronchial cancer. 4. They may be latent, in which case they are not found before autopsy. As to their route of propagation, it seems that they spread not only through lymph channels and blood vessels but also through the bronchi by aspiration. Most of the contralateral metastases are of the cavitary or epidermoid type. Radiologically, they are seldom miliary but often nodular, taking the form of multiple or isolated rounded opacities. As mentioned, the early and the secondary metastases are a bad prognostic sign, but late metastases in the contralateral lung are amenable to surgical therapy.

The Surgical Aspects of Portal Decompression. C. W. Hughes and E. J. Jahnke. Am. J. Gastroenterol. **24**:372-377 (Oct.) 1955 [New York].

Of 52 patients with portal hypertension who had end-to-side portacaval and splenorenal shunt operations, follow-up studies were completed in 30. Twenty-eight (93.4%) of the 30 patients had portal hypertension caused by intrahepatic block, and in only 2 (6.6%) was it caused by extrahepatic block. No patient was denied surgical intervention because of severe dysfunction of the liver. The first patients operated on had had hemorrhages from esophageal varices. Because of the highly satisfactory results of the operation in these patients, its indications were extended to encompass those patients with portal hypertension and extensive esophageal varices in whom hemorrhages had not occurred. Only 2 of the 30 patients had a shunt performed as a prophylactic measure. The direct portacaval shunt operation proved to be the procedure of choice, since a larger anastomosis can be obtained between the two systems by this method than by a splenorenal shunt, which is more difficult technically to perform and more time-consuming. Preoperatively, esophagoscopy was carried out routinely to determine size and extent of esophageal varices; manometric pressure readings were taken in the esophageal varices without complications. Techniques of portal venography and portacaval and splenorenal anastomoses are presented. Comparison of preoperative and postoperative manometric pressures taken in the portal vein showed a drop in portal pressure of over 200 mm. of sodium chloride solution after shunting procedures in most of the patients. Preshunt vena cava pressures were observed to range up to 220 mm. of sodium chloride solution; after the shunting procedures, the portal pressure equalized with the venacaval pressure and obviously could not be dropped below the initial venacaval pressure. Postoperative studies of the esophageal varices by esophagoscopy showed disappearance of some of the varices and decrease in size and pressure of others. When pressure readings were obtainable in the remaining varices, they were comparable to the pressure in the portal vein after the shunting procedure. While there appeared to be a correlation between the portal vein and esophageal varix pressures, there did not appear to be a correlation between size of the varices and tendency toward hemorrhage. Only two patients had minor hemorrhages from esophageal varices postoperatively, but both had demonstrable esophageal varices. Postoperative liver function studies showed temporarily increased dysfunction apparently related to anesthesia and operative trauma. Alterations in hepatic function, however, persisted only for 7 to 10 days. Only two patients died of liver failure as a result of surgery. The authors believe that maximum preoperative preparation, minimal anesthesia and operative trauma, minimal blood loss, and the use of chlortetracycline (Aureomycin) postoperatively for 10 days is responsible for keeping the mortality rate to a minimum and for the gratifying results thus far obtained.

The Medical Aspects of Portal Decompression in Cirrhosis. I. C. Plough. Am. J. Gastroenterol. **24**:378-383 (Oct.) 1955 [New York].

Portal hypertension and collateral venous pathways are frequently a late complication of cirrhosis, brought about by constriction of the intrahepatic portal bed by fibrosis and nodular regeneration of the damaged liver. Such patients may appear to have recovered completely from hepatic decompensation, only to bleed suddenly from esophageal varices. The only effective operations to reduce portal hypertension appear to be those in which a direct shunt is constructed from the portal venous system to the inferior vena cava or its branches. The source of bleeding should be accurately determined by x-ray and endoscopic examination. The nature of the liver disease and the specific location of the block in the portal system must be decided by careful, complete medical evaluation before the operation. Intractable ascites is not an indication for the shunt operation. Shunt operations may be done on patients with varices from which hemorrhage did not occur, but the value of the operation has not yet been established with statistical reliability, because very little is known of the natural history of esophageal varices. Severe impairment of liver function is a relative contraindication to operation. More than a slight degree of jaundice and depression of the serum albumin below 2 gm. per 100 cc. make the operation very hazardous. In such patients, the chances of recurrent hemorrhage must be balanced against the markedly increased operative mortality in coming to a decision. Patients selected for shunt operations demand very careful attention from the internist before, during, and after operation. Preoperative treatment consists of rest, proper diet, and withdrawal of alcohol.

There is no need for blood transfusion, which carries the hazard of homologous serum hepatitis, except after hemorrhage. Patients with severe liver damage are extremely susceptible to sedatives and narcotics, particularly morphine. These medicaments should be used in reduced doses or not at all. The duration of operation and anesthesia must be kept as short as possible. Hypotension must not be permitted to occur. Careful blood and fluid replacement is necessary. The routine postoperative use of chlortetracycline (Aureomycin) is recommended because of its reported good effect in hepatic coma. Conservatism is urged in ambulation of patients convalescent from operation. Because of recent evidence that high protein feeding is occasionally toxic after shunt operation, it is recommended that there be no forcing of the patient's protein intake.

Indications and Contraindications in Hypodermoclysis with Hyaluronidase in Surgery of the Digestive Tract. A. G. Weiss and L. Hollender. J. chir. **71**:673-686 (Oct.) 1955 (In French) [Paris, France].

Hypodermoclysis with hyaluronidase permits the use of the subcutaneous route of administration of parenteral fluid therapy, which is more physiological than the intravenous route. The authors have used it successfully over 300 times in patients who had had surgical interventions on the digestive tract. Hyaluronidase triples the rate of absorption of fluids administered subcutaneously, thereby eliminating local stagnation and distention. The rate of absorption is a function of the nature of the liquid injected. Isotonic sodium chloride solution of 9 per thousand penetrates more rapidly than 5% glucose solution, but the latter is absorbed faster than alcohol solution of 19 per thousand. Vitamin C, adrenoxyl, Phenergan, and other agents inhibit the effect of hyaluronidase and distinctly slow up the process of absorption. Macromolecular fluids injected subcutaneously with hyaluronidase are poorly absorbed. The method has certain definite contraindications. It should not be applied to patients whose metabolism is seriously disordered, those who are in acute or chronic shock or peripheral collapse, or those who need rapid increase of their circulating fluid volume. It is also not advisable in diabetics; patients with malignant disease; those with local infection or septicemia; those receiving corticotropin, cortisone, antihistaminics, or estrogens; those with certain dermatoses, notably eczema; those with cellular hyperhydration; and those with protein deficiency.

Early Post-Cibal Symptoms Following Gastrectomy: Aetiological Factors, Treatment and Prevention. W. M. Capper and R. B. Welbourn. Brit. J. Surg. **43**:24-35 (July) 1955 [Bristol, England].

In an attempt to collect reliable data on some of the controversial aspects of early postcibal symptoms in patients who have undergone gastrectomy, the authors sent a questionnaire to some 50 physicians and surgeons whom they knew to be particularly interested in gastric surgery. This paper is based on replies to these questionnaires, on recent publications, and on data secured by the authors themselves. They differentiate two types of early postcibal symptoms: the dumping syndrome proper and bilious vomiting. Early postcibal symptoms improve spontaneously during the first 12 to 18 months after operation; after this the incidence remains constant. Patients with extensive lesions at the time of operation tend to have less severe postcibal symptoms. Women on the whole fare worse than men. Postcibal symptoms are rare after gastroenterostomy. After gastrectomy there is no clear evidence that their frequency or severity bears any relation to the amount of stomach resected. An antecolic anastomosis possibly gives better results than a retrocolic. There is no evidence that a valve or the site of attachment of the afferent loop is significant. Postcibal symptoms are less persistent and less severe after a Billroth 1 anastomosis; loss of weight is less and colic and diarrhea are also less frequent, but the recurrence rate after the Billroth 1 procedure for duodenal ulcer is higher than it is after gastrojejunal anastomosis. In the initial stages of postcibal symptoms, explanation and reassurance are important. Careful analysis of dietary habits is valuable. Milk, sweet things, and food in liquid form may be causative factors. Meals should be taken dry and drinks only between meals. Lying down for half an hour before a meal greatly reduces bilious vomiting, and lying down to eat or for half an hour after food reduces dumping. Local anesthetics by mouth, hexamethonium bromide, and sodium bicarbonate, all before meals, may improve dumping symptoms. Bilateral paravertebral splanchnic block with procaine probably gives the greatest relief, which may be permanent. Surgical measures to give relief should be considered only when symptoms are severe and disabling and have persisted for at least 18 months after operation. Enteroanastomosis, jejunoplasty, and Roux-en-Y anastomoses usually relieve bilious vomiting, but relapse is common. As a primary procedure, the Roux-en-Y anastomosis prevents bilious vomiting. After any of these procedures, constant watch must be kept for recurrent ulceration. Support for the afferent loop and lesser curvature of the stomach may relieve or prevent dumping symptoms. Conversion to a Billroth 1 anastomosis usually relieves bilious vomiting, dumping symptoms, and diarrhea, causes increase in weight, and reduces fecal fat loss. Jejunal and colonic replacement of the stomach gives similar results, but jejunal ulceration is common after the former. In the present state of knowledge, conversion to a Billroth 1 is the procedure of choice for the surgical treatment of all types of postgastrectomy symptoms where a gastrojejunal anastomosis is present.

Operative Cholangiography. J. H. Gifford and S. C. Kahlstrom. West. J. Surg. **63**:605-606 (Sept.) 1955 [Portland, Ore.].

The studies reported were concerned with the proper evaluation of operative cholangiography. Two groups of cases, each consisting of 100 consecutive cholecystectomies for cholelithiasis, were investigated. All of these patients were operated on by a group of three surgeons who are associated as partners in the same office. In the first group, operative cholangiography was not used in any instance, and the decision to explore the common duct was based on palpation of a stone or the clinical indications of jaundice, dilatation and thickening of the duct, or a contracted gallbladder in patients with active symptoms. In this group the common bile duct was opened in 29 patients. Stones were found and removed in nine instances, while the remaining 20 patients had their ducts explored unproductively. In the second group, operative cholangiography was carried out in each instance, and the common bile duct was opened in 27 instances; 23 of these ducts were opened on cholangiographic evidence of stone, and stones were actually found in 21 patients, while in 2, air bubbles had been mistaken for stones. In the other four patients, in whom the cholangiogram showed no stones, the common duct was opened on clinical indications. Residual stones were proved in six patients and strongly suspected in another eight patients of group one, whereas in group two stones were left behind in only three patients. The authors conclude that the so-called clinical indications for common duct exploration are fallible and that they lead to exploration of the wrong ducts. Operative cholangiography is not infallible, but it is a more accurate method for determining the presence of common duct stones than palpation or clinical indications.

Surgical Treatment of Local Carcinoma Recurrences and Metastases, Respectively. H. Rosolleck. Arch. klin. Chir. **280**: 573-576 (No. 6) 1955 (In German) [Berlin, Germany].

Surgical treatment was practiced for local recurrences or easily accessible metastases in 22 patients, of whom 20 had been operated on previously for carcinoma of the breast, one for carcinoma of the penis, and one for carcinoma of the anus. The operation for local recurrences or metastases was preceded, in all of the patients, by a thorough clinical examination that definitely excluded the occurrence of generalized (distal) metastases. Extensive excision far into the healthy tissue is imperative. The survival time after the primary operation varied from 2 to 17 years, and the survival time after the operation for local recurrence or metastases varied from three months to six years. Because of the difficult conditions prevailing after the war, most patients did not receive irradiation treatment after the primary operation. When local recurrences or metastases were first observed, the patients first were referred to the roentgenologist for irradiation treatment, but irradiation alone failed to remove the tumor tissue and surgery had to be done. The fallacy of the statement made by some roentgenologists that surgical treatment preceding roentgen irradiation for local recurrence or metastases is not advisable because results of subsequent irradiation of scar areas are poor was demonstrated. Since life was considerably prolonged in some of the patients who underwent surgical treatment for local recurrence or metastases, the author pleads for surgical removal (with the exclusion of distal metastases) with subsequent roentgen irradiation, a method of management that is superior to that of roentgen irradiation alone. Hormone therapy does not seem to be appropriate in patients with local recurrence or metastases of cancer of the breast; it should be reserved for patients with generalized metastases in whom surgical treatment or roentgen irradiation is no longer feasible.

NEUROLOGY & PSYCHIATRY

Poliomyelitis Complicating Pregnancy. J. R. Bergquist and W. P. Sadler. Minnesota Med. **38**:668-673 (Oct.) 1955 [St. Paul].

Five hundred sixty-eight patients with acute anterior poliomyelitis were admitted to the contagion division of the Minneapolis General Hospital during the 1952 poliomyelitis epidemic. There were 88 women between the ages of 15 and 45 years, and 24 (27.3%) of them were pregnant. It has been estimated that between 6.2% and 11% of the female population in the child-bearing age will be pregnant at any one time. While the exposure rate was found to be higher in the nonpregnant woman than in the pregnant, the incidence of poliomyelitis in the pregnant women reported on by the authors confirms the statement by other workers that the attack rate is apparently higher in the pregnant woman. Three of the 24 women died, giving a maternal mortality rate of 12.5%, which is not greater than that in the nonpregnant women with poliomyelitis. Five of the 24 women aborted; giving an abortion rate of 20.8%, no higher than that expected for the general population. Of the 24 women, 12 were in the third trimester of pregnancy, 6 in the second, and 6 in the first. All three deaths occurred among the women in the third trimester. Eight of the women in the third trimester had the spinal paralytic type and four the bulbar spinal type of poliomyelitis. Of the six women in the second trimester, two had the nonparalytic type, three the spinal paralytic type, and one the bulbar type of the disease. Of the six women in the first trimester, four had the nonparalytic type and two the spinal paralytic type. Ten of the 12 women in the third trimester died or had severe residual paralysis. Thus, the most severe cases occurred in the last trimester of pregnancy, showing the varied picture poliomyelitis can present. Severe residual paralysis resulted in 8 (33.3%) of the 24 women, and mild residual paralysis in 7 (31.4%). There were four respirator cases in the entire group. Early tracheotomy, endotracheal suction, bronchoscopy, and positive pressure administration of oxygen greatly facilitated delivery in the respirator cases. The labor was conducted according to accepted standards. Most of the patients delivered spontaneously, and it was felt that labors were definitely less painful and shorter than in normal pregnant women; this might have been the result of relaxed perineal muscles and high pain threshold. Analgesic, amnesic, and sedative drugs are interdicted. Pudendal block with procaine was adequate anesthesia for most patients. Postmortem hysterotomy was unsuccessful to effect fetal salvage. Growth and development in surviving infants were normal.

The Clinical Response of Psychoneurotics to Chlorpromazine. M. Silverman. J. Ment. Sc. **101**:640-643 (July) 1955 [London, England].

Chlorpromazine hydrochloride, or Largactil, was given to 50 patients with psychoneurotic disorders in outpatient departments of general hospitals. Chlorpromazine was given in oral doses ranging from 25 mg. three times a day to 75 mg. three times a day. Approximately three-fifths of the patients gained substantial benefit from the treatment. Anxiety states showed a better response than the other diagnostic groups. This supports the view that the main effect of the drug is in the relief of tension. Some obsessional states showed material improvement. Some investigators suggested that obsessional patients should not undergo prefrontal leukotomy until chlorpromazine has been given a trial. Hysterical and depressive reactions did not respond well. Patients in the first four decades fared better than the older age groups.

Prolonged Sleep Treatment in Mental Disorders (Some New Psychopharmacological Considerations). H. Azima. J. Ment. Sc. **101**:593-603 (July) 1955 [London, England].

A prolonged state of sleep, approximating as much as possible the normal physiological state, was accomplished by the combination of different barbiturates and chlorpromazine (Largactil). The minimum daily sleep time was 20 hours, and the average duration of treatment, 25 days. This report is based on a study of 25 patients who were followed up for five months or more. These 25 patients had not responded to any other form of treatment, ranging from electric shock to long-term psychotherapy, and in each case the sleep treatment was used as the last resort. The group included eight patients with schizophrenia, two with manic depressive psychosis, three with obsessive compulsive neurosis, nine with mixed psychoneurosis, two with hysteria, and one with character neurosis. Improvement was noted in 60% of the cases. This improvement was based upon social and behavioral normalization. There were very few complications: two transitory maculopapular rashes; postsleep convulsive seizures in two patients, one being a recognized epileptic before treatment; and one case of pneumonia, which responded very rapidly to antibiotics. The following tentative list of indications for prolonged sleep treatment is proposed: neuroses, in particular conversion hysteria, anxiety hysteria, and borderline cases; hypochondriacal and psychosomatic syndromes; and schizophrenic reaction with preponderance of affective alterations. Patients with obsessive compulsive neuroses do not respond to sleep, and patients with mania respond to chlorpromazine alone.

Columnotomy in the Treatment of Unreduced Dorsolumbar Vertebral Fractures with Cord Lesions. G. J. Renes. Arch. chir. neerl. **7**:269-279 (No. 3) 1955 (In English) [Arnhem, Netherlands].

In Indonesia, where many hospitals are overcrowded and understaffed, inadequately treated traumatic injuries, such as cord lesions caused by unreduced vertebral fractures, are not uncommonly seen. Most of these injuries are caused by falls from trees. Twenty-three patients with persistent cord lesions caused by unreduced dorsolumbar vertebral fracture were treated surgically. Two are still in plaster jackets; in another patient the operation had to be discontinued because of simultaneous injury to the parietal pleura and severe hemorrhage from a lumbar artery, causing shock. Twenty patients remain for discussion. In seven of these only a laminectomy was carried out. This report is chiefly concerned with the 13 patients, who, after preliminary laminectomy, were treated by columnotomy and reduction of the spine. These patients were operated on from 5 to 27 months after the original injury. A columnotomy with reduction of flexion-angulation and posterior dislocation was carried out using La Chapelle's operation as modified by Allaart. Postoperative roentgen examination revealed that complete reduction was obtained in only one case; 2 remained unchanged, the other 10 cases showing reduction of flexion-angulation by an average of 14.4 degrees. Posterior dislocation in eight cases was completely reduced in two and partially reduced in six. Five patients were greatly improved, two were moderately improved, two slightly improved, three patients remained unchanged, and one patient became slightly worse. In this series clinical improvement appeared to be dependent on the degree of reduction of flexion-angulation. Serious delay in treatment did not worsen the results of operative reduction by columnotomy in these unreduced cases.

A Case of Transverse Myelitis Following T. A. B. Inoculation. T. P. H. McKelvey. J. Roy. Army M. Corps **101**:191-195 (July) 1955 [London, England].

The author presents the history of an 18-year-old soldier in whom a transverse myelitis of the cervical spinal cord developed 15 days after he received a second injection of T. A. B. (typhoid, paratyphoid A and B) vaccine. It was considered that the spinal cord lesion was probably a thrombosis affecting the cervical cord. The absence of other apparent cause of the transverse myelitis—e. g., trauma, syphilis, or other infection, bacterial or viral—and its relatively close sequence to his T. A. B. and other inoculations led to the consideration that it might be associated with those inoculations. Neurological sequelae after T. A. B. inoculation have been classified as syndromes of radiculitis, or plexitis, and mononeuritis, of polyneuritis and Guillain-Barré syndrome, of Landry's paralysis and myelitis, and of cerebral and meningeal forms. Such sequelae occur most commonly after a second inoculation. In the case described here, the immediate effect was upon the cervical spinal cord involving the fifth cervical to first thoracic segments with no evidence of cerebral, brain stem, or meningeal involvement. There was no further spread. Death did not occur, but recovery was far from complete, there being residual weakness in the muscles of the upper limbs, particularly those innervated from the eighth cervical and first dorsal segment, and slight spastic weakness of the lower limbs. It is now thought that the pathogenesis of such neurological complications after prophylactic inoculation is that of an anaphylactic reaction affecting blood vessels. Success in treatment of encephalomyelitis after rabies inoculations, where a similar mechanism has been postulated, has been reported with antihistamines and cortisone. Antihistamine drugs and cortisone were not used in the case reported here. However, it is felt that consideration should be given to their immediate use in all cases showing evidence of neurological lesions after prophylactic inoculation, especially where there is evidence of spinal cord involvement.

PEDIATRICS

The Pulmonary Hyaline Membrane Syndrome. S. S. Stevenson and L. E. Laufe. Pennsylvania M. J. **58**:1101-1103 (Oct.) 1955 [Harrisburg, Pa.].

The pulmonary hyaline membrane syndrome has shown a real and alarming increase in incidence in the last 15 years. It now seems to be responsible for half the total mortality among premature infants and for more neonatal deaths in all live-born infants than any other cause. The infant presenting this syndrome, usually born prematurely or by cesarean section or to a diabetic mother, has mild respiratory difficulty shortly after birth as if he had aspirated amniotic fluid. He then seems to be well for three or four hours, after which breathing becomes progressively more labored. Repeated roentgenograms show increasing diffuse haziness of the lung fields, and the infant becomes more and more cyanotic. Approximately 50% of such babies die, usually before they are 48 hours old. Microscopic examination of the lungs reveals extensive atelectasis, vascular congestion, and an eosinophilic hyaline-like membrane that lines occasional dilated alveoli and alveolar ducts. Experiments with guinea pigs have shown that, when amniotic fluid, which has a thromboplastin-like activity, is superimposed upon pulmonary edema, 20% of the animals exhibit the respiratory symptoms of the disease and present the complete syndrome at postmortem examination. It seems probable, therefore, that the human disease is produced when aspirated amniotic fluid becomes mixed with a pulmonary exudate. The formation of pulmonary exudate in human infants may be due to several causes, including irritation of the lungs by high concentrations of oxygen. This last may well be important, especially in premature infants. The increase in the incidence of the pulmonary membrane syndrome, which occurred simultaneously with that of retrolental fibroplasia, took place during the years in which incubators capable of maintaining high concentrations of oxygen became available. Further work on the origin of the syndrome should be directed toward elucidating the causes of pulmonary edema in the neonatal period. Certain practical suggestions for the prevention and treatment of the disease can, however, be made on the basis of present knowledge. 1. Place newborn infants in a prone position. They will not smother, and constant postural drainage will be established. 2. Aspirate the stomachs of infants born by cesarean section to free them from amniotic fluid and debris. 3. Restrict oxygen to the amount needed to preserve life and prevent cyanosis. The concentration of oxygen should never exceed 45%. 4. Observe all newborn infants for heart failure and proceed to rapid digitalization if failure appears. 5. Prophylactic antibiotic therapy should be given to every newborn baby with respiratory difficulty, especially when it is accompanied by atelectasis. 6. Be prepared to withdraw air from the pleural cavity if pneumothorax develops and makes it necessary. 7. Withhold food and parenteral fluids from infants with this syndrome until convalescence becomes obvious (usually within 48 hours). Cortisone, estrogen, and the fibrin-lysing substances are potentially dangerous and should be avoided. Bronchoscopy, which cannot remove foreign substances far down in the bronchial tree and which is traumatizing in newborn infants, should not be attempted.

Treatment of Thyrotoxic Children with Thiourea Derivatives: Long-Term Follow-Up and Recent Experiences. R. H. Kunstadter and A. F. Stein. A. M. A. Am. J. Dis. Child. **90**:373-380 (Oct.) 1955 [Chicago].

Thiourea derivatives have been used by the authors during the last 12 years in treating 13 girls and 4 boys aged 5 to 15 years for mild to severe primary hyperthyroidism. The results obtained in these children, nine of whom were first reported on in 1949, may provide answers to the following questions concerning the advisability of prolonged treatment with the thiourea drugs. 1. Is permanent "cure" possible? 2. What dose should be administered and how long should the drug be taken? 3. What is its effect on growth and development? 4. What happens to the size of the goiter and the exophthalmos? 5. What are the advantages of prolonged medical treatment? The original nine patients have been observed for periods ranging from 6½ to 12 years; follow-up in the other eight varied from 4 months to 6 years. All the patients were hospitalized at the time treatment was begun. They were ambulant and received sedation for sleep only when it was deemed necessary. They remained in the hospital until clinical improvement appeared and/or the basal metabolic rate began to fall—usually not longer than two or three weeks. Five patients in all underwent thyroidectomy—one because of a thyroid nodule suspected of being a neoplasm, one because of marked enlargement of the thyroid, one because of psychotic episodes and cardiac complications during early treatment, one, who was badly disturbed, because of poor cooperation, and only one because of drug failure. Eight of the 12 patients followed under medical treatment alone are in remissions that have lasted 5 years or more in six and from 2 to 5 years in two. Treatment in the other four patients is continuing. The eight patients in remission received treatment lasting from 6 to 36 months. They tolerated large doses, in most instances full adult doses, without evidence of intoxication. Indications are that large initial doses result in earlier response, lessen the likelihood of early relapses, and may shorten the duration of treatment. Growth and development, including sexual maturation, progressed normally through puberty into adulthood in all the patients followed in remission for long periods of time. Goiter and exophthalmos have disappeared completely in some patients; in others, small or moderate goiters or mild exophthalmos, or both, are still present. Treatment with thiourea derivatives can not only be expected to produce "cures" of five years or more in a large percentage of patients, but it may also make it possible to avoid the complications of surgical intervention and the disturbances of endocrine balance resulting from thyroidectomy.

Congenital Absence of the Spleen. D. W. Polhemus and W. B. Schafer. Pediatrics **16**:495-497 (Oct.) 1955 [Springfield, Ill.].

A case of congenital absence of the spleen accompanied by persistent atrioventricularis communis, pulmonary atresia, right aortic arch, and transposition of the heart to the right side; partial situs inversus involving liver, gallbladder, pancreas, stomach, and duodenum; and accessory lobe of the left lung is described in a newborn infant girl, who died suddenly when 7 days old. She was born by spontaneous cephalic delivery and weighed 3,240 gm. (7 lb., 2 oz.), and her respiration was spontaneous and without dyspnea. She had persistent cyanosis that increased with crying and activity and was not benefited by administration of oxygen. Heart sounds were heard best over the right side of the heart. There was also a soft heart murmur late in systole in this area. Agenesis of the spleen without other anomalies is excessively rare, whereas an increasing number of infants have been observed with certain specific anomalies in association with congenital absence of the spleen. This syndrome was originally described as including splenic agenesis, persistent atrioventricularis communis, partial situs inversus, accessory lobe of the left lung, and abnormal mesenteric attachments. In three cases of this type collected from the literature, a diagnosis of the syndrome was made before the patient died because of the findings of Heinz-Ehrlich bodies, or of Howell-Jolly bodies, target cells, and other abnormal elements in the peripheral blood of an infant with known congenital heart disease. Every baby having an obscure type of congenital heart disease should have peripheral blood studies with this syndrome in mind. If there are any of a variety of abnormalities observed in the blood, and particularly if fluoroscopy reveals transposition of the abdominal viscera, ante-mortem diagnosis of this syndrome can be made.

Defective Hemostasis: I. Hemophilia: A Pediatric Review. C. Weihl. Ohio M. J. **51**:983-985 (Oct.) 1955 [Columbus, Ohio].

Hemophilia, one of the classical hematological diseases of childhood, is no longer considered a single disease but a group of closely related diseases. The utilization or conversion of prothrombin into thrombin during the clotting process requires the presence of active thromboplastin in addition to the platelet factor and the tissue thromboplastin factor. Several substances normally present in the plasma contribute to the production of active thromboplastin. These substances have come to be known by several names; a deficiency of any one of them leads to a prolongation of clotting time and the clinical syndrome of hemophilia. The term of plasma thromboplastin factor A (PTF-A) is proposed for one of these substances and the clinical disease that occurs when it is deficient should be called hemophilia A. The other plasma thromboplastin factors, namely PTF-B and PTF-C, may be deficient and responsible for the defective clotting time, and the clinical syndromes caused by their deficiency should be called hemophilia B and hemophilia C. The diagnosis of hemophilia A (classical hemophilia) depends on a history of a characteristic hereditary pattern (sex-linked recessive trait), a finding of persistent bleeding in a male patient, usually beginning early in life, and the demonstration by laboratory means of a deficiency in plasma thromboplastin factor A (PTF-A or antihemophilic globulin). That the defect is caused by an absence of PTF-A is shown by mixing the patient's plasma with normal plasma and observing that the defect is corrected, whereas mixing the patient's plasma with plasma from a patient who is known to have hemophilia A fails to correct the defect. Hemorrhages will occur in spite of the most patient efforts to protect the child from injury. Their treatment requires, in addition to the usual local hemostatic measures, transfusion of fresh or frozen plasma in which the PTF-A, which rapidly deteriorates in blood stored in the fluid state, is retained for relatively long periods. The clinical syndrome caused by a deficiency of PTF-B cannot be distinguished from true hemophilia. It also seems to be inherited as a sex-linked recessive trait, occurring only in male patients. Ordinary laboratory tests again show prolonged clotting and decreased prothrombin consumption. Plasma of a patient with this disease readily corrects the defective clotting of patients with known hemophilia A, and vice versa. Since PTF-B, in contrast to PTF-A, is relatively stable in stored blood and plasma, patients with hemophilia B can be treated with a transfusion of ordinary stored blood. Hemophilia C differs from the A and B varieties in that it is inherited as a dominant trait and affects both males and females. The tendency to bleed is much less pronounced, and hemarthroses are rare. The clotting time may be either normal or prolonged, but impaired prothrombin utilization as in hemophilia A and B is shown by the prothrombin consumption test. Plasma from patients with this disease will correct the defect in clotting observed in patients with PTF-A and PTF-B deficiency, and vice versa. PTF-C, like PTF-B, is relatively stable, so that the patient with hemophilia C may be transfused with stored blood when necessary to promote coagulation.

UROLOGY

Latent Carcinoma of the Bladder. C. I. Cooling. Brit. J. Urol. **27**:221-223 (Sept.) 1955 [Edinburgh, Scotland].

The term latent carcinoma has been employed in cases in which the primary tumor is detected only at postmortem examination or not until after metastases have produced symptoms. The author presents two such cases. The first patient was a 53-year-old woman, who had had a swelling of the neck for about two years. It had increased rapidly in the previous eight months and had caused pain. Examination revealed a large mass of hard lymph nodes in the left supraclavicular fossa. This mass was fixed to the deep structures and was obviously malignant. A biopsy of the mass revealed a highly cellular carcinoma, but no opinion of the possible origin of the tumor could be suggested. Nasopharyngoscopy, bronchoscopy, and gastroscopy were carried out, but all failed to reveal any primary tumor in the accepted common sites of origin for such a metastatic tumor mass. The mass in the neck was treated by x-ray therapy as though it were a primary tumor, and in three months the mass resolved completely. Six months later, edema of the right leg developed and the right kidney became palpable, but the woman refused admission to the hospital for further investigation. A few days later she had a cerebral thrombosis from which she died. Postmortem examination revealed a hard, sessile, nodular tumor of the bladder, 3 cm. in diameter, around the right ureteric orifice, which had infiltrated through the whole thickness of the bladder wall. A chain of involved lymph nodes extended from the iliac vessels to the celiac axis. The second patient, a woman aged 72, complained of a lump on the chest wall. Histological examination after removal of the lump revealed a highly pleomorphic carcinoma, which was thought to be a metastasis from a carcinoma of the breast, but there was no evidence of such a tumor. Two months later, symptoms of frequency of micturition and hematuria led to studies on the urinary tract, which revealed a large tumor of the right wall of the bladder, which had infiltrated out to the pelvic wall. The woman died a month later. Each of these women presented histological evidence of deep infiltration and invasion of both vascular and lymphatic channels.

Hanging Bladder Stones Formed on Unabsorbable Suture and Ligature. J. H. Levack. Brit. J. Urol. **27**:239-241 (Sept.) 1955 [Edinburgh, Scotland].

While innumerable cases have been reported of foreign bodies in the bladder becoming thickly encrusted, no case of hanging stone as found in the two patients presented here could be found in the literature. In the first patient, a woman aged 42, cystoscopy revealed what seemed to be a calcified papilloma hanging from the anterior wall of the bladder. It was seen to be attached by a pedicle to the bladder wall. There was generalized cystitis. Suprapubic cystotomy disclosed that the calculus was attached to the bladder by a nylon suture. Part of this suture was incorporated in the calculus. The rest of the suture, which was buried in the bladder wall, was detached and the whole specimen was removed. The bladder was closed with catgut. Chemical analysis of the stone disclosed that it consisted entirely of phosphates. The history of this woman revealed that, at a sling operation about two years before, the technique of Millin had been followed, and nylon sutures had been used to transfix the two ends of the fascial slings above the bladder neck. One such stitch had eventually broken partly through the bladder wall at its inner surface. The second patient, a 60-year-old man, had undergone a transvesical prostatectomy. After the operation he felt well, but five months later he reported that lately he had had some bladder pain and frequency of micturition. Cystoscopy revealed a small calculus hanging from the scar area on the anterior wall of the bladder. The stone was voided on the day after the cystoscopy, and after that bladder pain and frequency ceased. Inspection of the specimen revealed that a small calculus had formed on a knot of linen thread. This stone also consisted entirely of phosphates. It is surmised that linen thread had been used for hemostasis.

The Male Gonorrhea "Carrier": Report of Seven Cases. J. B. Bittner and G. O. Horne. Brit. J. Ven. Dis. **31**:155-159 (Sept.) 1955 [London, England].

Gonorrhea is apparently becoming a much more innocuous disease in both sexes. The authors call attention to the male gonorrhea "carrier," a man who has the disease and is capable of transmitting it but who has no symptoms or symptoms so slight that they are ignored. Seven such cases were encountered in four years in a venereal disease clinic. The subclinical infection of the carrier can be diagnosed only by very thorough bacteriological investigation. When this condition is suspected, the investigations should include a stained smear and culture of at least one of the following: urethral scraping, urinary threads (if present), centrifuged urine deposit, prostatic secretion, and centrifuged prostatic urine deposit. The likelihood of success will obviously depend on the standard of techniques used, particularly for culturing the gonococcus. If the patient is symptom-free, more than one positive result should be sought if possible before a diagnosis of gonorrhea is made. A gonococcal complement fixation test should always be done in such cases, but this test has certain limitations, and it should not be relied upon for diagnosis. The importance of the male carrier should not be overrated, but in areas in which the incidence of gonorrhea is increasing or is not decreasing rapidly enough as a result of currently used methods of control, the possibility of male carriers contributing to the infectious pool (usually attributed to females) should be considered.

INDUSTRIAL MEDICINE

An Appraisal of Periodic Health Examinations. R. J. Bolt, C. J. Tupper and O. T. Mallery Jr. A. M. A. Arch. Indust. Health **12**:420-426 (Oct.) 1955 [Chicago].

Shortly after World War II, members of the department of medicine and the institute of industrial health of the University of Michigan Medical School and Hospital were approached by certain industrial organizations in the state of Michigan for the purpose of instituting routine annual checkup examinations for the executive personnel of the interested companies. The system adopted consisted of conducting all examinations on an inpatient basis. This was done for the following reasons: 1. It would afford the examinee a satisfactory examination without repeated visits on an outpatient basis. 2. It would afford a much closer physician-patient relationship and allow for the carrying out of indicated special studies. 3. It would allow for the institution of necessary treatment in the hospital and assure more adequate instruction and follow-up. 4. This system would afford an opportunity to evaluate various laboratory and x-ray procedures when employed in the absence of symptoms and aid in establishing the value or lack of value of these tests as screening measures in asymptomatic persons. The various examinations are outlined. They were initiated in 1947 and have continued to the present time. This analysis covers the five year period from July, 1947, to July, 1952. During this period of time, 943 examinations were done on 500 persons; 481 were men and 19 were women. The average age of those examined was 48.6 years, with a range of from 32 to 70 years. Two-thirds of the examinees were between the ages of 40 and 55. On the initial examination, 52% of the 500 persons examined were found to have one or more defects requiring treatment. Of all defects found on the first examination and for which treatment was advised, 69.8% were not known to exist prior to the examination. On subsequent examinations of the same persons, from 12.7% to 20.3% were found to have new abnormalities requiring treatment. The percentage of unknown defects suggested on the basis of the history and physical examinations was 87.7%. The routine and ancillary studies were responsible for the establishment of otherwise unsuspected diagnoses in 12.3% of the 351 defects found requiring treatment. These figures illustrate the fact that adequate histories and physical examinations continue to be the basic elements for success in this type of examination. The percentage of positive x-rays and/or laboratory studies that reveal significant disease in the absence of signs or symptoms is small.

Uranium Mining Operations on the Colorado Plateau. J. D. Torrey and P. W. Jacoe. A. M. A. Arch. Indust. Health **12**:375-377 (Oct.) 1955 [Chicago].

In the mining of uranium on the Colorado Plateau, the occupational hazards are those that could be anticipated, except that the problems are multiplied because of the geographical location, the lack of water, the lack of electrical power, and many other shortages. The evidence obtained in five years of study indicates that in order of their seriousness the occupational hazards are as follows: internal alpha radiation, dust, effects of uranium and vanadium as metals, and miscellaneous hazards. The primary hazard involved in mining uranium arises from the alpha emitters of radon, RaA, and RaC'. The most economical way to control the hazard is by well-planned ventilation. This calls for an engineering study. Inclines, shafts, and stope mines will require different ventilation systems.

THERAPEUTICS

Antagonism Phenomena Between Various Micro-Organisms: Yeasts and Bacteria. M. Bizot. Presse méd. **63**:1251-1252 (Sept. 24) 1955 (In French) [Paris, France].

The simultaneous culture of two micro-organisms in the same medium is usually unfavorable to one of them. In vitro experiments on the antagonisms of yeasts and bacteria showed that the ascosporic yeasts of the Saccharomyces type always inhibit the growth of anascosporic yeasts of the Candida type and of certain bacteria, without significant decrease in vitality. The anascosporic yeasts can inhibit the growth of certain microbes, notably micrococci, but in doing so they undergo some decrease in vitality. This effect, proved in vitro, justifies the time-honored practice of administering brewer's yeast. The phenomenon seems to be linked to the life of the cell, which fact contraindicates the therapeutic use of dead yeasts (powdered or granulated). Ultra-high yeast would appear to be the best therapeutic agent, because its optimum temperature is close to that of the human body and thus permits constant effectiveness in the digestive tract. The anascosporic yeasts are completely inhibited by some germs, such as Proteus, and this inhibition can go to almost total lysis of the yeast. In contrast, Saccharomyces boulardii inhibits the growth of Proteus organisms without decrease in proliferation; the alcoholic action of S. boulardii is not sufficient to explain this inhibition. The coexistence of pathogenic organisms with a therapeutic yeast does not affect its normal development. Theoretically, therefore, its administration is feasible to patients with sepsis.

Erythromycin in Human Brucellosis. O. Urteaga B., P. Larrea R. and J. Calderon M. Antibiotic Med. **1**:513-522 (Sept.) 1955 [New York].

The authors made studies on 14 patients with brucellosis, of whom 7 were in the acute and 7 in the chronic phase of the disease. Erythromycin was administered orally in tablet form, the daily dose of from 1.2 to 2.4 gm. being given in three divided doses. The total dose required to eliminate the febrile attack varied in the acute cases between 20 and 30 gm., administered over a period of from 9 to 16 days, while in the chronic cases, treated according to the biological cycle of the organism, similar results were obtained with small doses of 4.8 to 7.2 gm. administered in two or three days. The authors cite literature reports, which demonstrate that there are two stages of brucellosis that correspond to the life cycle of the Brucella organism—the extracellular bacterial stage and the intracellular rickettsial stage—which have different histobacteriological characteristics and cause the toxifebrile and the apyretic syndromes respectively. The antibiotic acts directly on the organism by making the circulating medium hostile. This suppresses the interstitial reproduction of Brucella and compels the bacteria to take refuge in the cell protoplasm, where antibiotic action is almost nil. In this way the antibiotic destroys the extracellular phase of the organism and the corresponding toxi-infectious syndrome. Then the Brucella enter their defensive intracellular phase and the patient experiences a remission, that is, the apyretic stage. The characteristic of the organism of being able to multiply in the interstitial mediums, as well as in the interior of the cell, explains the undulant nature of the disease. The antibiotic, which destroys the septicemic bacterial extracellular phase, interferes with the immunity mechanism, and so relapse occurs after variable periods. The authors were able to demonstrate in some of their patients that, by giving erythromycin in smaller doses and only for a few days, the bacterial phase of the disease was controlled and a clinical remission resulted, yet the immunobiological mechanisms were not interfered with. Short relapses again yield to small doses of erythromycin, and the patient's own defense processes are stimulated. Each passage of the organisms from the tissues to the circulating medium acts like an autovaccination that can be controlled by the therapeutic activity of the antibiotic, that is, the antibiotic acts as an adjunct to the patient's autovaccination processes.

Desensitization in Streptomycin Allergy of Nursing Personnel. H. Jahrmärker. Ärztl. Wchnschr. **10**:873-876 (Sept. 23) 1955 (In German) [Berlin, Germany].

The author presents the histories of two nurses in whom severe sensitivity to streptomycin developed and in both of whom specific desensitization was carried out. The first nurse had prepared from 30 to 40 streptomycin injections daily and had given inhalation treatments with streptomycin. At the end of five months a conjunctivitis developed, also acute urticaria on face, neck, and arms. A skin test with streptomycin produced a positive reaction, whereas tests with other possible allergens proved negative. Although the symptoms of streptomycin sensitivity subsided after treatment with calcium and histamine preparations, recurrences increased in frequency despite the fact that this nurse no longer prepared the streptomycin injections. Specific desensitization was carried out with the aid of subcutaneous injections of streptomycin. These injections were given two or three times a week, beginning with subthreshold doses that were gradually increased. In the first nurse, a good and persisting tolerance for occupational exposure was obtained. In the second nurse, difficulties were encountered during desensitization. Despite slow increase in the desensitizing doses, the treatment had to be interrupted several times. Furthermore, it proved impossible to confer tolerance for therapeutic doses, which would have been important for an intercurrent tuberculosis. Generally the application of small desensitizing doses is sufficient and safe. Clinical success seems to depend not so much on the size of the doses used for desensitization as on the degree of sensitivity that existed before treatment. The degree of tolerance that can be achieved by desensitization is limited as to dose and differs individually. The immunologic foundations and the technique of desensitization are discussed. If sensitivity to streptomycin becomes severe in nursing personnel in whom symptomatic treatment is not sufficient, either desensitization must be attempted or further contact with streptomycin must be carefully guarded against.

Effect of Cortisone and Certain Other Steroids on the Peripheral Vasculature in Arthritis. A. Woodmansey and J. W. Beattie. Ann. Rheumat. Dis. **14**:293-297 (Sept.) 1955 [London, England].

A defective peripheral circulation is frequently observed in rheumatoid arthritis, and many of the therapeutic measures employed in this and allied conditions result in an increased peripheral blood flow. The authors report investigations on cortisone and certain other steroids. Altogether 57 patients (56 women and 1 man) were studied; 43 had rheumatoid arthritis and 14 osteoarthritis. They were investigated in five groups, each group receiving one of the following steroids: cortisone, testosterone, deoxycorticosterone acetate with ascorbic acid, progesterone, and estradiol monobenzoate. Only one patient, wtih rheumatoid arthritis, received two steroids. Cortisone was the only steroid that consistently produced an improvement in the peripheral vascular status and in the arthritic condition. The peripheral vascular effect may be an important factor in the pharmacological action. It is suggested that this effect of cortisone takes place via the thermo regulatory mechanism.

Trial of Chemotherapy of Myeloid Leukemia by Three New Agents: Demecolcine, Thiocolchicine, and Myleran. J. Bousser and D. Christol. Presse méd. **63**:1229-1231 (Sept. 21) 1955 (In French) [Paris, France].

Six patients with chronic myeloid leukemia were treated with demecolcine (Compound 12,669), a colchicine derivative. This drug has a definite effect on leukocytosis, percentage of immature elements in the blood, and splenomegaly; it can produce excellent remissions, but only at dosage levels at which its effects are not strictly controllable and constant checking is necessary. Accidents occur that are serious and unforeseeable. The results obtained with demecolcine are highly transitory. Another colchicine derivative, N-desacetyl-thio-colchicine (R´261 Roussel) was tried in seven patients with the chronic form of the disease and proved to be similar to demecolcine, in that its activity was so temporary as to require a maintenance program of treatment and its toxicity was pronounced. It may even have contributed to the death of one patient. Myleran, or GT 41 (1-4-dimethylsulphonyl-oxybutane), on the other hand, gave encouraging results in a group of 18 patients, 14 with chronic myeloid leukemia, 2 with terminal myeloblastic attack, and 2 with myeloid splenomegaly with myelosclerosis. This was especially true for the first category and not for the second and third. Myleran is well tolerated if no more than 10 mg. is given per day. The authors usually gave three, sometimes four, 2 mg. tablets a day but reduced this number to two when leukocytosis was moderate (about 50,000 white blood cells per cubic millimeter). The effect of the drug on leukocytosis was progressive and complete, and there were no disturbances of red blood cells or platelets. The quality of the remissions obtained was good, and they seemed to last only a little less time than those induced by radiotherapy. Myleran has the advantage of being inexpensive and easy to administer. This drug is worthy of being used in the current therapy of myeloid leukemia.

Desoxycorticosterone and Salicylates in Treatment of Rheumatic Diseases. L. Schiavetti and F. Ferraris. Riforma med. **69**:901-904 (Aug. 13) 1955 (In Italian) [Naples, Italy].

The antirheumatic effect of a preparation containing desoxycorticosterone acetate (0.0002 gm.), sodium salicylate (0.4 gm), vitamin A (0.005 gm.), and vitamin C (0.2 gm.) was studied in 16 patients with third or fourth stage rheumatoid arthritis, 12 with fibrositis, and 30 with arthrosis. The preparation was given rectally in daily doses of three suppositories for 10 days to the patients of the first group, who had had previous treatments, including cortisone, and to those with fibrositis. The patients with arthrosis were given two suppositories daily for 20 days. The elevated erythrocyte sedimentation rate dropped in all the patients with rheumatoid arthritis, 30% of whom were benefited in their subjective symptoms and 40% in their joint function. The best results were obtained in the patients with fibrositis in whom the subjective and functional symptoms disappeared within one week. As for the third group of patients, the therapy was more effective in those with acute arthrosis than in those with arthrosis of long standing in whom even the subjective symptoms were only slightly influenced. A simultaneous study made on 18 patients with the same clinical pictures, who were given rectally only sodium salicylate and vitamin A in doses equal to, or double, those given the above patients, indicated a less marked antirheumatic activity in general of this combination, an insufficient action on pain and the other rheumatic signs, and a less marked action on the erythrocyte sedimentation rate. The salicylic-steroid combination thus gave results superior to those obtained with salicylates alone. The effect of these two substances administered concurrently is potentiated because of their complementary action on the two phases—that of muscular involvement and that of tissue involvement—of the rheumatic inflammation. Side-effects were practically absent in the patients, which fact was partly due to the presence of the two vitamins in the preparation. The vitamins favor the antirheumatic activity, protect the adrenal glands, and probably favor the peripheral utilization of the hormone present in the preparation.

Hormonal Treatment of Cancer of Breast. R. Grinberg, L. Jaroslavsky and G. Stutman. Rev. Assoc. méd. argent. **69**:163-166 (June 15-30) 1955 (In Spanish) [Buenos Aires, Argentina].

The treatment of cancer of the breast through modification of the endocrine balance started with surgical and roentgen castration, proceeded with the administration of hormones and, later, with adrenalectomy or a hypophysectomy. Cancer of the breast in its relation to hormones can be divided into the following three groups: (1) tumors related to estrogens, (2) those related to androgens, and (3) those that are independent of either hormone. Tumors related to estrogens improve from administration of androgens or as a result of surgical operations aimed at eliminating production of estrogens. Tumors related to androgens improve from administration of estrogens. No definite treatment for tumors of the independent type has been found. The effect of hormonal treatment on metastases is fairly good for skin or bone metastases, moderately good for lung metastases, and poor for metastases in the brain or in the liver. Failure of the administration of androgens, estrogens, progesterone, and cortisone points out the independent nature of the tumor. The authors conclude that: (1) hormones constitute a useful treatment of cancer of the breast (in many cases in the advanced stage of the disease the results are favorable, although transient); and (2) adrenalectomy and hypophysectomy have prolonged the life of many patients with cancer of the breast in the advanced stage. These operations are grave for the poor condition of the patients in that stage of the disease. They should be replaced in the future by adequate medical treatment. The number of patients with cancer of the breast who do not respond to hormonal treatment is very large. Therefore, further investigations concerning treatment of value for the independent type of cancer of the breast are of importance.

PATHOLOGY

Lower Nephron Nephrosis: I. A Pathogenesis for Degeneration of the Kidney Tubules. C. O. Rice, J. H. Strickler and N. Lufkin. Am. J. Surg. **90**:547-557 (Oct.) 1955 [New York].

Complete electrolyte, water, nitrogen, and caloric balance studies were done on 102 patients who had been operated on for severe major illness. Of the 102 patients, 48 died and autopsies were performed. In 21 of these, degeneration of the kidney tubules was observed, while in 27 no degeneration of the kidney tubules was revealed. Of the 21 patients with degeneration of the kidney tubules, the organic cause for death as indicated by the pathological report was insufficient in 8 (group 1) but the electrolyte studies made during life revealed definite electrolyte imbalance. In 13 patients (group 2) organic disease was found on autopsy, which could have contributed to the development of the disturbance in the electrolyte balance that had been revealed by the electrolyte studies made when the patients were still alive. The remaining 27 patients (group 3) in whom electrolyte imbalance was known not to be present, as illustrated by the blood electrolyte studies or as indicated by history, were chosen selectively as controls; tubular degeneration was not found in any of them on autopsy. In analyzing these three groups, it was observed that an electrolyte imbalance and tubular degeneration of the kidneys were constantly associated regardless of other organic disease. Conversely, when tubular degeneration was not found in the kidneys (group 3), no electrolyte imbalance had existed, as indicated by the history or the laboratory findings. In some of the patients in group 3, the kidneys did not show tubular degeneration, although the disease causing death may have been severe; in others, the short duration of the illness would seem to indicate that an electrolyte imbalance would not have had time to develop. The authors suggest that, when tubular degeneration of the kidney is found on autopsy, electrolyte imbalance may have been present before death. The consistency of these corollary findings, and their absence when an electrolyte imbalance has been known definitely not to exist, suggests the relationship even in the face of other organic disorder. Conversely, when an electrolyte imbalance has existed and has contributed to the death of a patient, it is likely that tubular degeneration of the kidneys will be found. These corollary findings of electrolyte imbalance and degenerative changes in the kidney tubules suggest a pathogenesis for lower nephron nephrosis, the cause of which has long eluded specific identification.

Lower Nephron Nephrosis: II. The Function of the Kidney When Tubular Degeneration Exists. C. O. Rice and J. H. Strickler. Am. J. Surg. **90**:558-561 (Oct.) 1955 [New York].

The electrolyte intake and output figures and serial blood electrolyte pictures in the 21 patients with degeneration of the kidney tubules reported on by the authors in the preceding paper are discussed. Only 3 of the 21 patients had terminal anuria. The tubular degeneration in these three patients was no greater than that observed in the other 18 patients who did not have anuria. On the whole, the excretion of water by the kidneys was found to be only slightly diminished in the patients with severe tubular degeneration. There was no constancy in the nature of the electrolyte imbalance in relation to the extensiveness of the tubular degeneration. The findings, however, indicated a significant decrease in the excretion of sodium and chloride and, to a lesser extent, of potassium and nitrogen when tubular degeneration of the kidneys was present. These findings suggest the need for reducing the intake of these elements in proportion to their excretion in the urine, lest their retention result in further chemical imbalance. In many of the patients who died with tubular degeneration of the kidneys, glycosuria was not present despite the high blood sugar level. These findings made the authors aware of the need for observing and treating an elevated blood sugar level, as well as treating the electrolyte imbalance when these conditions exist simultaneously.

The Severity of Aortic Arteriosclerosis in Certain Diseases: A Necropsy Study. D. L. Creed, W. F. Baird and E. R. Fisher. Am. J. M. Sc. **230**:385-391 (Oct.) 1955 [Philadelphia].

Although the actual mechanism involved in the development of human arteriosclerosis has not been clearly elucidated, the possibility that certain diseases may influence its evolution is suggested by the fact that syphilitic aortitis, diabetes mellitus, xanthomatosis, hypothyroidism, and lipoid nephrosis, as well as hypertension, are often accompanied by severe arteriosclerosis. The authors evaluated the severity of aortic arteriosclerosis found in 1,223 autopsies performed on males at Veterans Administration Hospital during the seven year period from 1946 to 1952 inclusive. The severity of aortic arteriosclerosis was tabulated in each instance according to the major disease accounting for the patient's death as disclosed at autopsy. Only those diseases that appeared to be related to a statistically significant increase or decrease of aortic arteriosclerosis are considered in the results. The data obtained reaffirmed the observations of an increased severity of arteriosclerosis in patients with hypertension. Bronchogenic carcinoma was also associated with such an increase. This appears to be directly associated with this type of malignant tumor, rather than the presence or absence of hypertension or old age in these patients. The rapid weight loss of patients with bronchial carcinoma likewise cannot account for the increased severity of arteriosclerosis, since such alteration in the nutritional state was found also in other neoplastic diseases not associated with comparable degrees of arteriosclerosis. Whether the smoking factor is important in the development of arteriosclerosis cannot be affirmed or refuted. The high incidence of adrenal metastases (45% in this series) in bronchogenic carcinoma might suggest the possible effects of adrenal destruction in the development of human arteriosclerosis. However, similar degrees of arteriosclerosis were noted in patients without adrenal metastases. The degree of arteriosclerosis was decreased rather than increased in patients with Laennec's cirrhosis and in those with malignant lymphoma. The authors feel that an explanation for a decreased severity of arteriosclerosis in patients with hepatic cirrhosis might well reside in the clearing action of estrogen upon serum lipoproteins, failure of estrogen inactivation being a characteristic of Laennec's cirrhosis. In addition, the presence of jaundice, which is associated with increased serum phospholipids, an important factor in the stabilization of serum lipid emulsions, may also play a role. The frequent hepatic involvement observed in patients succumbing to malignant lymphomas and leukemia may account for the decreased severity of arteriosclerosis in patients with these diseases. A prolonged poor nutritional state, which many of these patients exhibit, is also frequently associated with a decreased severity of arteriosclerosis.

Adrenocortical Activity and Reactivity as Measured by Eosinophil Counts. A. Hoffer. Canad. M. A. J. **73**:463-465 (Sept. 15) 1955 [Toronto, Canada].

It is impossible to assay adrenocortical activity and reactivity by means of eosinophil counts unless the total diurnal rhythm is represented. No valid comparison is possible between groups of subjects unless the activities are compared at a time when the rate is not changing, that is, either at the sleeping eosinophil peak or the waking eosinophil trough. The reactivity must be measured by the rate of change of eosinophils.

***Rheumatic Activity in Auricular Appendages Removed at Mitral* Valvoplasty.** R. M. Clark and W. Anderson. Am. J. Path. **31**: 809-820 (Sept.-Oct.) 1955 [Ann Arbor, Mich.].

Seventy-eight auricular appendages from patients with progressive cardiac failure presumably of rheumatic origin were available from valvoplasty procedures performed at the Toronto General Hospital. Since the most recent operation in this particular group was carried out at least 18 months ago, sufficient time has elapsed to report on the incidence of recrudescence and on any relationship that might exist between the reappearance of clinical rheumatic fever and the extent and nature of the auricular lesions encountered. Portions of the 78 auricular appendages were examined microscopically. In only 10 of them were lesions completely absent. Histological evidence of rheumatic activity in the form of Aschoff nodules was found in 50% of the patients, sometimes many years after the initial attack and in the absence of signs of clinical activity. These lesions were almost twice as frequent in patients under 31 years of age as in the remainder of the series. The change observed most frequently was basophilic connective tissue degeneration, which was present in 54% of the cases. The other lesions observed included cellular infiltration in endocardium and myocardium in 51%, fibrosis in 40% and intra-auricular thrombi in 42%. Thrombi were most frequently found in association with auricular fibrillation, but no correlation could be found between Aschoff nodules and arrhythmias. The presence of Aschoff lesions and the postoperative course could not be correlated. Two possibilities are suggested by the fact that granulomas were encountered more frequently in the younger age group. First, the rheumatic process, although subclinical, may be continuously active. Alternatively, the presence of lesions could be explained by recrudescences becoming less frequent with advancing age. According to the clinical histories, rheumatic fever was present in some of these patients from 6 to 41 years before operation. Incidental to the study of the heart material was the study of 29 specimens of lung taken for biopsy. They were examined for parenchymal and vascular changes that might indicate chronic pulmonary hypertension. About one half of the 29 specimens of lung were found to show changes indicative of chronic pulmonary hypertension.

ANESTHESIA

Local Anesthesia in the Newborn. R. E. Straith, J. L. Teasley and L. T. Moore. Plast. & Reconstruct. Surg. **16**:125-134 (Aug.) 1955 [Baltimore].

The authors feel that the correction of congenital deformities such as harelips is too often postponed much longer than necessary. At between 1 and 4 weeks of age a newborn infant, with adequate preoperative medication, can be operated upon under local anesthesia for the correction of these deformities without the danger of general anesthesia. Local anesthesia has five advantages. First, it is much safer than general anesthesia in infants. Second, there is more room about the operative site when anesthesia apparatus is eliminated. Third, there is no disturbance of fluid intake and output, which often leads to serious problems in infants. Fourth, adrenalin, which can be used with the local anesthesia, markedly reduces the blood loss, especially in very vascular tumors. Fifth, local anesthesia is much less expensive. At the Straith Clinic in Detroit, babies with cleft lip and other deformities are operated upon at about 7 days of age. The baby will usually be gaining weight and should weigh at least 6 lb. (2,721.55 gm.), take fluids normally, and have a normal hemoglobin level, temperature, pulse, and respiration. One hour before operation, 2 or 3 oz. of the food formula are given by gavage. Immediately after this, a suppository of pentobarbital sodium (Nembutal) is inserted as far as possible, and the buttocks are taped tightly shut to prevent its being expelled. The child is then returned to the crib until it is brought to the operating room 45 minutes later. The baby is placed on the operating table, with its head in a rolled towel "doughnut" with adhesive passing under the doughnut and around the forehead. The baby is "mummified" with adhesive tape under the back to both wrists and across the hips and knees. The chest is not immobilized, so that, in case of vomiting, the head and chest can be turned to prevent aspiration. After the baby is in proper position for operation, the depth of analgesia is determined by pinching the ear lobe. If there is a response to this stimulus, 4 or 5 mg. of meperidine (Demerol) hydrochloride is injected intramuscularly in a 6 lb. baby. If the response is delayed, but definite, 2 or 3 mg. is given. If there is little or no response, no Demerol is given. Periodic stimulation is used to keep informed as to the baby's analgesia level. Oxygen may be given through the nose but is rarely necessary. In babies with cleft lip, 5 cc. of 1% Xylocaine is injected at each infraorbital foramen, in the base of the columella, around each superior buccal fornix and at the corner of the mouth, and usually gives excellent anesthesia. Several hundred infants with congenital deformities have been operated upon with local anesthesia and some form of sedation without an anesthetic death.

On the Present-Day Therapy of Shock for Surgical Patients. J. S. Lundy. Proc. Staff Meet. Mayo Clin. 30:446-450 (Oct. 5) 1955 [Rochester, Minn.].

Lundy calls attention to a new factor that must be recognized when shock occurs during anesthesia. When a patient, adult or child, has been treated for some time with either cortisone or corticotropin, and this treatment has been stopped for some time, shock may appear suddenly. This type of shock can be fatal. It should be prevented by the preoperative preparation of such patients with cortisone, and the agent should be given postoperatively as well. Occasionally, a solution of dextran and hydrocortisone seems to maintain the average patient without resort to measures other than the giving of fluids. An equally soluble fluorohydrocortisone has been made available, in which the potency has been increased tenfold, so that 10 mg. of fluorohydrocortisone diluted in 500 cc. of dextrose has been effective. Very recently a preparation of hydrocortisone has been made available that is water-soluble and need not be diluted in more than 2 cc. of water. This preparation can be given in very small quantities. This is convenient and speeds up recovery. When blood has been lost, it should be replaced. However, it may not be necessary to replace all the lost blood. In cases in which surgical shock has occurred, with considerable loss of blood, excellent results have been obtained from first giving 500 cc. of the proper blood, followed by 500 cc. of a 6% solution of dextran in isotonic solution of sodium chloride containing 100 mg. of hydrocortisone. Administration of this solution is followed by the giving of a second bottle of blood, a procedure followed in turn by administration of another bottle of dextran, with or without the hydrocortisone. The author hopes that it will become possible to treat patients prophylactically against shock. He feels that it will probably not harm a patient to give him cortisone preoperatively and to repeat it on the day of operation and again in the first part of the postoperative period.

BOOK REVIEWS

The Practice of Dynamic Psychiatry. By Jules H. Masserman, M.D., Professor of Neurology and Psychiatry, Northwestern University, Chicago. Cloth. $12. Pp. 790. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, England, 1955.

Dr. Masserman has always been active in research as well as in clinical activities and, like many other psychiatrists, has developed his own formulation of the nature of emotional illness, which he presents with great facility. This book follows a previous volume called "Principles of Dynamic Psychiatry," in which he elaborated a theory of biodynamics, correlating concepts of behavior into a comprehensive system. Now he includes his theory of *Ur-defenses* (a group of commonly held beliefs that protect from fear and anxiety) to explain aspects of conduct. Insights gained from animal experiments are also presented. The volume discusses the psychiatric examination and reaction types, although a large portion is devoted to therapy—a wide range of subjects is listed in the index under therapy. There is a chapter that deals with the type of reports that should be presented to medical and nonmedical personnel. A detailed account of the historical background of psychotherapy and chapters on group therapy and musical therapy are features of the book. Many case histories are scattered through the text. The bibliography is extensive and the index adequate. The format is so modern that the headings have no capital letters. The whole text sparkles with mention of history, philosophy, literature, art, and music. There are extensive references to the work of other psychiatrists. This book presents such a personal bias and departs so far from the conventional that it cannot be considered a textbook but will be read largely to learn the author's particular point of view. In general it appears to sacrifice depth and integration to scope. It is recommended for stimulating supplementary reading.

Textbook of Occupational Therapy with Chief Reference to Psychological Medicine. By Eamon N. M. O'Sullivan, B.A., M.B., D.P.M. Cloth. 21s. Pp. 319, with illustrations. H. K. Lewis & Co., Ltd., 136 Gower St., London, W.C.1, England; (printed in Republic of Ireland by Kerryman Ltd., Tralee), 1955.

This book offers a balanced discussion of the practical aspects of occupational therapy. The opening chapter on definitions and history is lively and instructive. Successive chapters deal with general principles, with problems of organization and administration, with the special applications of occupational therapy in mental disease, and with the analysis of representative crafts such as woodworking. The author has gone to much trouble to give concrete details such as floor plans, and the section (beginning with page 67) on occupational opportunities for patients in the kitchen, dining halls, laundry, farm, gardens, grounds, seamstress's department, tradeshops, and engineer's department should be helpful. The many problems in disposing of items made in some occupational therapy are described. There is a good bibliography and an index. This book is recommended.

Systemic Lupus Erythematosus: Review of the Literature and Clinical Analysis of 138 Cases. By A. McGehee Harvey, M.D., and others. Reprinted from *Medicine*, vol. 33, no. 4, December, 1954. Cloth. $3. Pp. 291-437, with 25 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1955.

This monograph from the department of medicine of Johns Hopkins University is the most comprehensive review available of the symptoms, laboratory features, and treatment of systemic lupus erythematosus. Since the concept of this disease has broadened greatly in the last few years with the widespread use of the diagnostic plasma L. E. cell test, such a review is particularly timely. The authors have attempted to gain as complete a picture as possible of the natural history of this disease by analyzing the case histories of 138 patients with systemic lupus erythematosus and by correlating their findings with those in the medical literature. They have analyzed the effects of treatment on each of the manifestations of the disease. The review was compiled with the hope of bringing to light new avenues of approach to the study of lupus erythematosus; however, it should also serve as an excellent reference manual for the investigator and as a differential diagnostic aid for the clinician. Rapid reference is facilitated by the use of a detailed outline in the table of contents. The bibliography is extensive and current. The publishers are fully justified in reprinting this review in the form of a bound volume of good quality.

Wiederbelebung. Von Prof. Dr. H. Killian und Priv.-Doz. Dr. A. Dönhardt. Cloth. 24 marks; $5.70. Pp. 320, with 93 illustrations. Georg Thieme Verlag, Herdweg 63, (14a) Stuttgart, Germany; [Intercontinental Medical Book Corporation (subsidiary of Grune), 381 Fourth Ave., New York 16], 1955.

The authors of this book appear to be well informed about recent developments in pharmacology and anesthesiology and on this basis offer a thorough discussion of the entire subject of resuscitation. Preliminary chapters on definitions and history are followed by a review of the problems of resuscitation as seen from the viewpoint of gas exchange, cardiovascular regulation, temperature regulation, renal function (especially water and salt balance), the muscular and skeletal system, the psyche, and the autonomic nervous system. In connection with this last, there is a penetrating summary of current thinking about the use of drugs to influence or abolish the regulatory activity of the "vegetivum." This is followed by a substantial chapter on the treatment of apnea, of circulatory failure, of renal failure, and of severe pain. A short section on the transportation of the sick and injured includes several important collections of figures. A concluding section takes up the important varieties of asphyxia, of thermal and electrical injuries, and of injuries seen after atomic bombing. The information in this book is up-to-date and compactly presented. The illustrations are not only attractive but also valuable, since they show details of modern European apparatus. Bibliographies include American and Canadian works, and the index is good. The book should help to correct the unreasonable fear of acapnia that lingers from former days. It should be seen by everyone concerned with emergency work, anesthesia, premature infants, oxygen therapy, and first aid.

Applied Medical Bibliography for Students. By William Dosite Postell, Medical Librarian, Louisiana State University School of Medicine, New Orleans. Publication no. 259, American Lecture Series. Monograph in Bannerstone Division of American Lectures in Internal Medicine, edited by Roscoe L. Pullen, A.B., M.D., F.A.C.P., Professor of Medicine, University of Missouri School of Medicine, Columbia. Cloth. $4.50. Pp. 142, with 12 plates. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1955.

Despite the author's declaration that this book was designed for students, it seems to offer a great deal of useful information for several other types of reader. Part 1, dealing with historical bibliography, gives a condensed account of scientific and medical writing from the time of the Assyrian manuscripts through the beginnings of modern medical journalism in the mid-19th century. Part 2, dealing with modern bibliography, is a survey of medical libraries and their collections and a brief evaluation of a number of basic reference books, indexes to periodical literature, and journal collections, including general and specialty groups. In part 3, which describes methods of bibliography, the author outlines scientific investigation and gives in some detail the process of writing a paper and the techniques of compiling a final bibliography, including the two most commonly used forms of documentation. This little volume has considerable value as a reference tool for the individual researcher and for the small library. The appendix includes a bibliography of the various titles mentioned in the book, as well as a list of recommended readings. It is carefully indexed and is illustrated with reproductions of bibliographic tools such as various types of catalog cards, journal-holding files, and index pages. The author's style is smooth and uncomplicated. The book is highly recommended for libraries or for individual readers, as well as for medical students.

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

QUERIES AND MINOR NOTES

RECURRENT CARDIAC INFARCTIONS

To THE EDITOR:—*A 35-year-old white man had a posterior myocardial infarction in 1952 followed by an uncomplicated recovery. Four months ago he had an anterior infarction, again with a normal recovery. Both episodes were confirmed by electrocardiograms. At present his tracing shows evidence of only an old anterior infarction. There is nothing to suggest a ventricular aneurysm. A lung x-ray is normal; the cardiothoracic ratio is 16/29.5. He is slightly underweight. His blood pressure and the remainder of his physical examination are normal. This man's only complaint is dyspnea when he lies on his left side, and this is promptly relieved when he changes position. What is the most probable explanation for this symptom? What is the average life expectancy in a case of this kind?* *John M. Trapnell Jr., M.D., Philadelphia.*

ANSWER.—Regarding this inquiry, the cardiothoracic ratio of 16/29.5 suggests enlargement of the heart; therefore, dyspnea, even when it is only experienced when the patient lies on the left side, possibly suggests heart failure. However, since it apparently is relieved by change in position, extracardiac factors such as an arthritis of the dorsal spine, a hiatus hernia, floating lower rib or ribs, an abnormality of the splenic colon, a "Magenblasse," duodenal or gastric lesion, or even a gallbladder condition must be excluded. A trial of therapy for heart failure, with administration of digitalis and a sodium-restricted diet, might be essayed to see if the symptom is obviated. The average life expectancy in the case of a man with two acute coronary episodes would be from two to five years. A patient who has had three bona fide coronary occlusions is alive now for six years following the last and is apparently in "perfect health." The electrocardiogram still shows deep Q-waves. Another patient with bronchial asthma suffered three bona fide episodes of acute coronary occlusion and survived the last attack almost 10 years.

TUBERCULOSIS IN INFANT

To THE EDITOR.—*What treatment is indicated for an 11-month-old child with a large, firm, nontender cervical node of one month's duration and a positive patch test? Examination otherwise and chest x-ray are negative. The only therapy to date has been antibiotics for one week with no apparent change in the mass. If this should be tuberculous adenitis what therapy would be advised?*

Keith E. Vincent, M.D., Long Beach, Calif.

ANSWER.—Any 11-month-old child who reacts characteristically to tuberculin has tuberculous lesions that probably are multiple and may be in various parts of the body. Although it would be necessary to recover tubercle bacilli from the large, firm cervical lymph node for exact diagnosis of this particular disease, it is reasonably safe to assume that it is tuberculous and treat it accordingly. Antimicrobial drugs (streptomycin, aminosalicylic acid, and isoniazid) are in common use in such cases. Some prefer isoniazid alone, others prefer isoniazid and aminosalicylic acid, and still others administer all three of the major drugs simultaneously. Each of these drugs has a suppressive effect on tubercle bacilli, and when two are given in combination they may be more effective than either one alone. Moreover, such combinations delay emergence of resistance of tubercle bacilli to drugs. It would hardly be expected that one week of antimicrobial drug administration would result in an appreciable change in the large lymph node. The treatment probably should be continued for at least six months or even a year. If the node shows evidence of breaking down and becoming fluctuant, surgical extirpation would be indicated without interruption of drug administration. The child has other lesions; therefore, the removal of the one now presenting is not a cure for the disease. One or more of the other lesions may evolve to clinical proportions, which may be prevented by antimicrobial drugs. There is now a widespread movement for the administration of antimicrobial drugs to those who have recently converted from nonreactors to reactors to tuberculin without any other finding but the tuberculin reaction. Recent convertors are known to have at least microscopic tuberculous lesions. They are vascular, and the drugs may be expected to reach all tubercle bacilli. It is not yet known whether the bacilli are destroyed or only suppressed. In any event, cases have now been reported in which reversion of the tuberculin reaction has occurred following prolonged drug administration. It is still possible that only suppression has occurred to such a degree that bacilli have not multiplied and therefore tuberculoprotein is not being eliminated in sufficient amount to maintain sensitivity of tissues. However, some evidence has accrued that strongly suggests such treatment of recent tuberculin converters prevents development of acute tuberculous lesions such as meningitis, generalized miliary disease, and pleurisy with effusion.

GREASE GUN INJURIES

To THE EDITOR:—*Recently I had two cases of finger injury caused by penetration of hydraulic oil under high pressure. In one case there was a small laceration of the skin; in the other there was no visible laceration. The latter case proceeded through stages of inflammation, atrophy, and contracture; the finger finally had to be amputated. The other case occurred three weeks ago; the finger is still swollen and inflamed. I presume the inflammation is chemical. Penicillin was not expected to help and did not. Please comment on nature of these oil injuries and their proper management. Have you heard of such cases involving the eye or the male genital organ?* *J. B. Martin, M.D., Fredericktown, Pa.*

ANSWER.—Grease gun injuries to the hand have been reported a number of times in the literature. (Byrne, J. J.: Grease Gun Injuries, *J. A. M. A.* **125:**405 [June 10] 1944; Frank, E.: Hand and Finger Injuries Caused by Grease Under High Pressure, *Wien. klin. Wchnschr.* **67:**23, 1955; Mason, M. L., and Queen, F. B.: Grease Gun Injuries to Hand, *Quart. Bull. Northwestern Univ. M. School* **15:**122, 1941.) The writer has seen a similar injury of the nose but has seen no report of involvement of the eye or male genitalia. The injury is due to injection under high pressure, (from several hundred pounds up to 1,000 lb.) of lubricating grease from the nozzle of a grease gun. Similar injection of diesel oil may also occur accidentally in mechanics repairing motors. The injection may be quite painless, the finger or hand simply swelling suddenly and becoming numb. The part becomes white or yellowish-brown, and a small pin-point greasy wound is seen. There is often little or no immediate tenderness. Pretty soon, however, areas of gangrene of skin or entire digit occur, and associated with this are evidences of infection. Three factors are accountable for symptoms in this early stage: pressure of the grease, mechanical and chemical irritation of the foreign body, and infection. It would seem logical at this stage to open the digit both to relieve tension and to release as much as possible of the grease. After the initial stage of injury has passed, the grease sets up a chronic inflammatory reaction about the whole extent of the distribution of the grease. This may be extensive, especially if the initial pressure was high or if tendon sheaths and loose fascial spaces are invaded. In this stage it is advisable to dissect out the involved areas, which may require skin excision and replacement. Where residues of oil remain in the tissues, it seems logical to assume that in a certain num-

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

ber of cases chronic granulomatous lesions (oleomas) will occur; small ones have been encountered by this consultant. These chronic lesions belong to the same generic class as the paraffinomas, the oleomas that followed oil injection of hernias, hemorrhoids, breast plastics, and facial plastics of the past. Similar lesions were reported in the recruits of the German and Russian armies who injected oil beneath the skin to produce tumors for purpose of escaping service.

SYPHILIS AND PAIN IN KNEES

To the Editor:—*A man, aged 52, was found to have syphilis in 1946 and was treated with 10 million units of penicillin. He developed a sensitivity to penicillin and has been unable to receive any since. In 1952, he had pain on the medial aspects of the knees just above and below the joint line and had tenderness over this area. X-rays showed osteoarthritic changes, and an adventitious bursa was removed without relief. The pathologist reported round cell infiltration of the tissue. In 1954, x-rays showed a defect of the tibial plateau and bone adjacent on both tibias. The uric acid level was 5 mg. per 100 cc. A spinal tap was done, and a 4+ Kahn was reported. X-rays taken in May, 1955, showed a healing reaction of the involved areas of the tibia, so that the joint margins were reformed. He has continued to have pain. Colchicine preparations were tried without relief. Should this patient receive further treatment for syphilis, and, if so, should heavy metals be used? At present, neurological examination is negative. Would x-ray findings, such as a defect in the medial tibial plateau that later filled in within a year's time, be caused by syphilis?* *M.D., North Dakota.*

Answer.—The question posed as to the relationship of syphilis to the symmetric difficulty with this patient's knees could hardly be answered without the opportunity to see the patient and his serial x-rays. The description given of the lesions in the knees is compatible with the possible diagnosis of bilateral Charcot neuropathy, and the fact that the patient has had pain does not rule this out. Contrary to the usual textbook statement, Charcot joints are sometimes quite painful. On the other hand, the bilaterality of the lesions and the tendency to spontaneous healing of involved areas of the tibial plateau does not conform to the Charcot joint and renders this diagnosis relatively improbable. The positive Kahn test in the spinal fluid cannot be interpreted. It probably indicates that the patient has neurosyphilis. Flocculation tests on the spinal fluid are, however, relatively unsatisfactory, and, in addition, the information concerning the patient's spinal fluid examination is totally incomplete. One would wish to know the blood cell count, the quantitative protein content, a quantitatively titered complement fixation (not flocculation) test, and a colloidal test. While it seems relatively unlikely that the lesions in the patient's knees are due to syphilis, nevertheless, under the circumstances a therapeutic test is perhaps thoroughly justifiable. Since the patient is known to be penicillin sensitive, such a therapeutic test is probably best carried out with intravenously administered mapharsen, 60 mg., every second or third day to a total of 10 doses, plus 2 to 4 gm. of potassium iodide three times daily (e. g., 1 teaspoonful of the saturated solution given well diluted three times daily after meals). If there is not prompt relief from the pain within a couple of weeks on this treatment regimen, it may be assumed that the lesion is not syphilis. Arsenic plus potassium iodide is better for the purpose indicated than any of the broad-spectrum antibiotics. These have some treponemicidal effect, but this is substantially less than with penicillin or arsenic.

PROTEIN-BOUND SERUM IODINE

To the Editor:—*Kindly indicate corresponding values of basal metabolism tests and protein-bound iodine levels. In other words, a basal metabolism of +20, 30, 40, 50, or 60 corresponds to what iodine level in the blood?*

John P. Gifford, M.D., Vero Beach, Fla.

Answer.—The accepted normal levels of protein-bound serum iodine vary according to the technique employed in their determination but are generally in the range of 3.5 to 8 mcg. per 100 ml. of blood. Fluctuations in readings occur when an attempt is made to exactly reproduce tests of basal metabolic rate; similarly, minimal variations are noted in protein-bound iodine values. Thus, it is not possible to positively interchange these determinations in terms of each other. A severely myxedematous individual might have a protein-bound iodine level of 0.2 to 0.4 mcg.; in the moderate hypothroid state 1 to 2.5 mcg. would be expected, and a moderately severe thyrotoxic patient should present a reading of 10 to 12 mcg. with a corresponding basal metabolic rate of +40 to +60. It should be emphasized that a critical clinical evaluation is the most valuable diagnostic procedure in the determination of the status of any patient suspected of thyroid dysfunction.

CORTISONE SUPPRESSES RESISTANCE TO INFECTION

To the Editor:—*In treating acute rheumatic fever with cortisone acetate in doses of 100 mg. daily the following effects occurred in a 13-year-old boy who has been in bed for one year. On the 21st day an anal ulcer appeared. On the 28th day a tonsillar ulcer appeared. On the 30th day a temperature of 101.4 F (38.5 C) appeared with extensive swelling of the cervical areas bilaterally. This swelling simulated parotitis, which the patient had several years ago. These cervical swellings were indurated and erythematous, and the one on the left side ruptured with a discharge of pus. Before the skin broke there was an eschar 1 in. by 2 in. in area. After this the temperature dropped to 97.4 F (36.3 C). The right cervical swelling fluctuates but is not erythematous or indurated and has no eschar formation. The cortisone acetate therapy was discontinued on the 33rd day. The anal ulcer is healing, and the tonsillar ulcer is gone. It is now 18 days since the patient has had cortisone. The arthritis has gone, and the tachycardia remains at 122 per minute.* *A. G. Walters, M.D., Detroit.*

Answer.—It has been shown that cortisone may suppress resistance to infection. This depression of resistance has been observed in bacterial, viral, and parasitic infections in animals. Acneform eruptions and furunculosis have been reported during hormonal therapy. The use of cortisone in this patient is therefore contraindicated. The history of previous swelling of the cervical glands and the present recurrence of the swelling, with necrosis, ulceration, and purulent discharge is suspicious of tuberculous cervical lymphadenitis. It has been reported that inactive tuberculous foci may be reactivated during hormonal therapy and even after the cessation of treatment. The possibility of the coexistence of tuberculosis with the rheumatic fever should be ruled out.

SUSPECTED CRIMINAL POISONING

To the Editor:—*Blood and urine studies of a patient show the presence of arsenic. There is strong suspicion, albeit no proof, that a criminal attempt at slow poisoning was made. The patient decided not to bring the case into court. Has the physician the duty, or even the right, to make a report contrary to the wish of the patient?* *M.D., New York.*

Answer.—The inquirer does not state the basis for his suspicion of criminal poisoning, but it may be assumed that he has made an adequate investigation to rule out the possibility of accidental poisoning or poisoning in some way related to the occupation of the patient. In some jurisdictions there may be a legal obligation specifically imposed by statute or ordinance on the physician to report to the police a situation involving possible deliberate poisoning. The presence of a small amount of arsenic may be attributed to foods eaten by the patient, but where the quantity exceeds such amounts the possibility of deliberate poisoning may not be ignored. There is undoubtedly a duty placed on the practitioner to protect and save the life of his patient. In the well-known Scottish poisoning case of *Rex v. Pritchard*, Edinburgh, July, 1865, the victim's physician was severely criticized by the judge for his conduct, in that he took no action when he had become convinced that his patient was being poisoned. The judge said that no consideration of professional etiquette could stand in the way of the far higher duty "owed by every right-minded man to his neighbor" to prevent the destruction of human life, in which duty the practitioner had failed. As a general practice, when criminal poisoning is suspected, the patient should be moved to a hospital where the necessary treatment and investigation can be undertaken. This will protect the patient from the possibility of further poisoning, allow for a more conclusive diagnosis, and afford an opportunity for necessary investigation. Chapter 8, section 1, of the Principles of Medical Ethics points out that physicians as good citizens "should bear their part in enforcing the laws of the community and in sustaining the institutions that advance the interest of humanity." Chapter 1, section 1, similarly states in part that: "The prime object of the medical profession is to render service to humanity. . . ." The fact that a person who is guilty of an attempt at criminal poisoning may in effect be shielded by the physician who fails to call in the authorities to investigate represents a menace not only to the patient involved but to the community at large. The same principle is involved as in the case of a patient having a contagious disease who must be reported for the benefit of the community.

COLOSTOMIES

To the Editor:—*Does the use of an artificial anus on the left side shorten the life span of the patient? In such cases what is the best system to elicit intestinal movements for evacuation? Does the daily use of enemas to clean the large intestine cause atrophy of the peristalsis of the cecum and of the ascending colon? When enemas are used what quantity of water and size of the sound should be used? Is it advisable to use salted water for enemas?* *M.D., Argentina.*

Answer.—A left-sided colostomy in no way shortens the life of a patient, since there is sufficient colon left for normal function. The absorptive aspect of the right colon is not interfered with and enough of the left side of the intestine remains to absorb most of the water and allow for a fairly firm stool. On the question of daily evacuations, a daily enema acts in a cleansing fashion so that usually there are no movements between enemas. Daily enemas do not produce an atrophy of the colon or interfere with any general peristaltic movements. For some patients, an enema every second or third day will control the bowel movements. The amount of the enema varies from about a pint to a quart, depending on what works best for the patient, who rapidly learns how to obtain a good evacuation. Usually a 20 or 22 F. catheter is considered effective to introduce the enema into the colostomy opening, and the distance inserted varies from 10 to 25 cm. Enema water can be plain lukewarm water or slightly soapy water. Some patients with left-sided colostomies get along quite well without enemas. In time the intestine develops a fairly rhythmic function, and bowel movement usually occurs first thing in the morning. There may be two or three small movements during the day, which are readily handled with the modern colostomy apparatus.

PULMONARY FIBROSIS WITH EMPHYSEMA

To the Editor:—*Please describe the management of a case of bilateral pulmonary fibrosis with emphysema, cause undetermined, in a 49-year-old physician in general practice. There is some dyspnea with occasional wheezing, noticeable only on rapid climbing of hills or stairs. Kindly make special reference to: (1) prevention and treatment of respiratory infection, (2) amount and type of exercise, (3) special breathing exercises, and (4) use of bronchodilators and alternatives as iodides and arsenic.* *M.D., North Carolina.*

Answer.—The dyspnea in this patient is probably caused by diffuse airway obstruction, and management should be directed primarily toward keeping the airways open. The extent to which this can be accomplished depends on the mechanism of obstruction that may vary within the broad group of patients who are considered on clinical grounds to be suffering from emphysema. 1. By reducing inflammatory swelling of the bronchial mucosa, antibiotics help to restore patency of the airways when respiratory infection is present. A mixture of organisms is usually involved. Prophylactic use of antibiotics is not indicated unless repeated respiratory infections dominate the clinical picture. 2. Physical exercise up to the point of dyspnea is not contraindicated. 3. Special breathing exercises may be helpful if skilled instruction can be obtained. Such exercises often increase the patient's exercise tolerance and increase his ability to control bouts of dyspnea. 4. Bronchodilators provide the most direct and often the most successful means of relieving airway obstruction with its resultant dyspnea. Iodides and arsenic are not effective alternatives for bronchodilator therapy. Isopropylarterenol and similar agents are conveniently administered with a hand-operated nebulizer. It is important that the patient exhale maximally and then inhale the aerosol deeply so that it can reach the smaller airways. Bronchodilator therapy should be administered freely and, if effective, continued indefinitely.

AUTOPSIES

To the Editor:—*A patient with the probable diagnosis of lupus acutus disseminatus, aplastic anemia, and thrombocytopenia died in a hospital here. The family did not want an autopsy. No charity was involved. Could the coroner and hospital insist on an autopsy or had the wish of the family to be respected?* *M.D., California.*

Answer.—A hospital may request an autopsy but may not have one performed without the consent of the surviving heirs or next of kin. A coroner may insist upon an autopsy in any case coming within his custody within the limits of the statute in the particular state in question. In California, for example, various statutory provisions set forth circumstances under which autopsies may be ordered by the coroner, deputy coroner, justice of the peace, workman's compensation commission, superintendent of public health, and private individuals.

METHOD FOR GIVING THE SALK POLIOMYELITIS VACCINE

To the Editor:—*In* The Journal, *Aug. 13, 1955, page 1406, is a question and answer entitled "Method of Giving the Salk Poliomyelitis Vaccine." I feel that the answer to the question of whether the vaccine should be given by the single-syringe-multiple-needle change method is misleading to the general practitioner. It has been established that the virus of epidemic hepatitis can be transmitted by minimal amounts of blood or tissue juice that will always be present in a syringe if the plunger is drawn back. To recommend not to draw the plunger back is a rather dangerous recommendation in general and certainly not recommendable for the Salk vaccine. Little is known about the immunization, but it is well established that vaccination and immunization given intracutaneously or subcutaneously are far more effective than the intravenous route. Granted that the chances of hitting a blood vessel are minimal, I believe that in a new procedure, such as the Salk vaccination, everybody should strictly adhere to the recommended procedure.*

Irving Park Boulevard at Broadway
Chicago.

GUNSHOT WOUND OF AORTA

To the Editor:—*I would like to comment on "Gunshot Wound of Aorta," Queries and Minor Notes section,* The Journal, *Dec. 11, 1954. One of the points the inquirer wanted to know was whether a .22 caliber bullet striking the abdomen and penetrating the abdominal aorta would stop a man at once. No mention was made by the consultant concerning the hydraulic effect of missiles on the large blood vessels of the body. A missile striking the abdominal aorta can kill instantly by rupturing the aortic valves, bursting blood vessels in the brain, and/or dilating the heart, producing cardiac standstill. It is my opinion that a .22 caliber bullet lacks the momentum to do this unless it is one of the high velocity special makes that several companies put on the market.*

TREATMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS WITH PREDNISONE AND PREDNISOLONE

Alfred Jay Bollet, M.D., Stanton Segal, M.D.
and
Joseph J. Bunim, M.D., Bethesda, Md.

Prednisone and prednisolone have been found to be approximately four times as potent as cortisone and hydrocortisone in suppressing the inflammatory manifestations of rheumatoid arthritis.[1] Since administration of these two synthetic steroids in moderate doses does not cause sodium retention or edema, they offer important advantages over previously used steroids. Cortisone and hydrocortisone have been employed in the treatment of systemic lupus erythematosus with considerable effectiveness in controlling many of the manifestations of this disease. These drugs, however, tend to intensify fluid retention and hypertension in patients with renal and cardiac involvement. It was thought advisable, therefore, to compare the relative merits of prednisone and prednisolone with the older steroids in the treatment of systemic lupus erythematosus and to determine the effectiveness and limitations of the newer steroids.

MATERIAL AND METHODS

This series consists of 10 patients with systemic lupus erythematosus whose disease had not been satisfactorily controlled at the time of admission (table 1). Their ages varied between 7 and 46 years, and the disease had been present for between 1 and 10 years. Nine patients were female; there was one Negro patient in the group. At the time of admission, four patients were receiving cortisone in daily doses of 37.5 to 100 mg., four were getting hydrocortisone, 60 mg. per day, and to one patient 112.5 mg. of cortisone and 40 units of corticotropin daily were being administered. One patient had not received any hormone therapy. With these various regimens, control of the disease was incomplete. The patients were having continual symptoms or periodic exacerbations of activity of the disease. Further, most of the patients exhibited some undesirable side-effects of hormone therapy (table 1). In two instances these side-effects were of a serious nature; one patient had an episode of psychosis while receiving 200 mg. of cortisone daily and another patient had frequent convulsive seizures, which stopped when cortisone therapy was discontinued.

All 10 patients demonstrated the L. E. phenomenon in peripheral blood and had some systemic manifestations of acute illness. Nine patients had joint symptoms, eight had anemia, and eight leukopenia. Four patients had severe renal disease, and, of these, two had a nephrotic syndrome. Three patients were observed to have convulsive seizures. Typical cutaneous lesions occurred in three.

In the initial period of observation, patients continued to receive the medicaments administered prior to admission. When warranted, the dose of steriod that had been given prior to and immediately after admission was gradually lowered in order to define more clearly the nature of the suppressed symptoms. In most instances, patients were allowed to have some escape from hormonal control. An abrupt change was then made from previous medication to prednisone or prednisolone without interrupting steroid therapy. Placebos were employed in such a manner that the patient was not aware when the switch was being made from the old to the new steroid. As the dose of the old steroid was decreased, placebo was substituted for the amount withdrawn and at the same time another placebo indistinguishable from prednisone or prednisolone was given. At a certain time, the antecedent drug was completely replaced by its placebo, and simultaneously the new steroid was substituted for its placebo. It should therefore be recognized that many of the symptoms that responded to prednisone had been also satisfactorily suppressed by cortisone or hydrocortisone.

The size of the initial, suppressive dose of prednisone or prednisolone varied roughly with the severity of the

J.; Black, R. L.; Bollet, A. J., and Pechet, M. M.: Metabolic Effects of Metacortandralone and Metacortandracin, Ann. New York Acad. Sc. **61:** 358 (May 27) 1955. (*c*) Bollet, A. J.; Black, R., and Bunim, J. J.: Major Undesirable Side-Effects Resulting from Prednisolone and Prednisone, J. A. M. A. **158:** 459 (June 11) 1955.

disease. After a period of observation long enough to determine the effectiveness of the suppressive doses on each manifestation of the disease, the dosage was tapered 5 mg. every five days, until recurrence of some symptoms developed. The next higher dose was then selected as the minimum maintenance dose for complete suppression of the disease. The patients were then observed while receiving this dosage for periods varying from two to eight months; the average length of follow-up was four months. Throughout the period of study, from the time of admission, all patients in the series were given a diet containing 3 gm. of sodium (5 gm. of sodium chloride) per day.

RESULTS

Dosage.—The initial suppressive daily dose varied between 20 and 60 mg. (fig. 1) and averaged 35 mg. In most instances, 30 or 40 mg. was given daily. The largest dose, 60 mg. per day, was given in case 6. This patient had been receiving 160 units of corticotropin gel per day at the referring hospital in another state. She was given only 60 mg. of hydrocortisone on the day of transfer, while en route to Bethesda. During this transition there developed rapidly spreading bilateral pneumonia and increased intensity of the facial rash, mucous membrane lesions, and arthritis. Circulatory shock supervened. Prednisone therapy was instituted immediately upon admission; 60 mg. was given the first day. Vigorous antibiotic measures were added, although the causative agent of the pneumonia was not demonstrable. Within 24 hours the patient was markedly improved, and the dose of prednisone was decreased to 40 mg. per day. This case illustrated the capacity of prednisone, supplemented with antibiotics, to control a very severe exacerbation of lupus erythematosus complicated by a serious intercurrent infection. Maintenance doses in the group of patients varied between 5 and 30 mg. per day, averaging 18 mg. Comparison of the maintenance dose of prednisone with the previous maintenance dose of steroid reveals that prednisone has about four times the potency of cortisone and a little over three times that of hydrocortisone in controlling the manifestations of systemic lupus erythematosus.

TABLE 1.—*Composition of Series of Ten Patients with Lupus Erythematosus at Beginning of Prednisone Treatment*

Case	Age	Sex	Race	Duration of Disease, Yr.	Previous Hormonal Therapy	Daily Maintenance Dose	Comment
1	41	F	W	4	Cortisone *	100 mg.	Incomplete control, edema, moonface, mental clouding, convulsions
2	29	M	W	8	Cortisone + corticotropin *	112.5 mg. + 40 units	Incomplete control, pustular rash, moonface, seizures
3	24	F	W	2	Cortisone *	50 mg.	Edema, acne
4	46	F	W	2	Cortisone *	75 mg.	Incomplete control with severe relapses, persistent infection, phlebitis
5	7	F	W	6	Cortisone Hydrocortisone *	200 mg. 60 mg.	Moonface, edema Acne
6	21	F	W	3	Corticotropin gel Hydrocortisone *	160 units 60 mg.	Incomplete control, amenorrhea Severe exacerbation
7	23	F	W	10	Hydrocortisone * Corticotropin (intermittent)	60 mg.	Moonface, increased edema
8	35	F	W	5	Cortisone * Corticotropin (intermittent)	37.5 mg.	Incomplete control, amenorrhea Increased edema, psychosis
9	42	F	W	7	Cortisone Hydrocortisone *	100 mg. 60 mg.	Incomplete control Incomplete control, hirsutism

* Therapy that patient was receiving at time of admission.

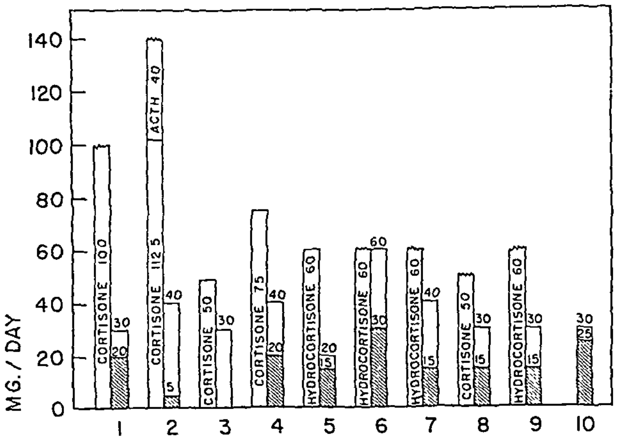

Fig. 1.—Dosage of steroid showing relative potency in 10 patients with systemic lupus erythematosus. For each case, first bar indicates maintenance dose of cortisone, hydrocortisone, or corticotropin at time of admission; a frayed top indicates incomplete control of symptoms. Second bar represents maximal amount of prednisone or prednisolone given. Cross-hatched area within second bar indicates minimum maintenance dose subsequently established. (Minimum dose not established for case 3 at time graph was drawn.)

None of these patients had a complete and sustained remission, and therapy was therefore not interrupted. One patient exhibited a definite change in the degree of activity of his disease (case 2). When initially seen, he was having systemic and pulmonary symptoms in spite of treatment with 112.5 mg. per day of cortisone plus 40 units per day of corticotropin gel. He experienced a severe exacerbation of these symptoms when the corticotropin was reduced to 5 units per day, even though the cortisone dosage was maintained. He was markedly improved when given prednisolone, 40 mg. per day. After four months of therapy with prednisolone and then prednisone, it was found that a dosage of only 5 mg. of prednisone per day was sufficient to prevent symptoms. Subsequently, the dose had to be increased to 10 mg. per day. As there was apparent change in the activity of the disease, this patient was not included in calculation of relative potency of the steroids. Two patients in this series were first given prednisolone for a period of six weeks and subsequently were transferred to prednisone therapy. No difference in potency, effectiveness, or side-effects was noted between the two drugs in these patients. Reference hereafter will be made only to prednisone, although some of the observations on these two patients were made with prednisolone.

Effect on Systemic Manifestations.—Fever was present in six patients and chills in two at the time prednisone therapy was begun; there was a rapid defervescence and disappearance of chills in all patients; normal temperatures were reached in 12 to 24 hours (table 2). Marked malaise was present in 10 patients and anorexia in 8; both cleared completely within a few days in all but 2 patients, who presented severe nephrotic syndrome. Joint pains in nine patients and objective joint findings in seven completely disappeared in all but one patient, who had nephrosis. In one of the two instances of splenomegaly, the spleen receded after two days of therapy, but in another patient, who had a greater degree of splenomegaly (two fingerbreadths below costal margin), there was no change. Generalized adenopathy diminished gradually over the course of a few weeks in two of four patients.

Table 2.—*Effect of Prednisone Therapy on the Manifestations of Systemic Lupus Erythematosus*

Manifestations	Cases, No.	Favorable Response	
		Cases, No.	Time
Systemic			
Fever	6	6	12-24 hr.
Chills	2	2	immediate
Malaise	10	8	1-4 days
Anorexia	8	6	1-2 days

Abnormal electroencephalogram	5	0	....
Hematological			
Leukopenia (less than 5,000 cells/cu. mm.)	8	6	1-6 wk.
Anemia (hematocrit less than 38%)	8	2	3 wk.
Serum proteins			
Hypoalbuminemia (less than 3.5 gm./100 cc.)	10	0	....
Hyperglobulinemia (above 3.5 gm./100 cc.)	4	0	....

The L. E. phenomenon was present in peripheral blood and was not influenced by prednisone therapy. The sedimentation rate was elevated above 25 mm. per hour (Westergren) in all 10 patients, with an average level of 85 mm. per hour. On prednisone therapy, a diminution in sedimentation rate occurred in all patients, but only in four did it return to normal levels; the average of the lowest values obtained in each patient on therapy was 48 mm. per hour. C-reactive protein was present in the serum of five patients when prednisone therapy was begun and disappeared in all, within one week.

Fig. 2.—Chest x-ray of patient in case 2 taken while patient was receiving daily doses of 112.5 mg. of cortisone and 5 units of corticotropin.

Effect on Skin and Mucous Membrane Lesions.—A typical facial rash of lupus erythematosus was present in two patients, and a lesion resembling that seen in discoid lupus was present in another (table 2). The erythematous malar rash disappeared within two weeks in both patients, and the chronic discoid rash improved gradually but had not entirely disappeared after three months of therapy. Mucous membrane lesions, consisting of shallow inflamed ulcerations, were present in three patients and cleared within two weeks of therapy.

Effect on Pulmonary and Pleural Manifestations.—Cough and pleuritic pain disappeared within a few days in all patients with these symptoms (table 2). Pleural friction rubs were present in three patients and cleared within three days of treatment. Chest wall tenderness, which was noted in two patients, slowly cleared over 7 to 10 days. Moist rales were present bilaterally in five patients, and definite clearing in most areas was noted in all patients during the first week of therapy; in three patients, however, patches of rales persisted throughout therapy. Radiological findings were noted in eight patients, consisting of parenchymal infiltrates and horizontal linear densities, usually accompanied by small pleural effusions. In six of these patients, complete or almost complete disappearance of these changes occurred during two to six weeks of prednisone therapy (fig. 2 and 3), but in the other two patients new parenchymal infiltrates appeared.

Effect on Cardiovascular Manifestations.—Mild dyspnea at rest was present in six patients and subsided in four (table 2). Aching, precordial pain, which was present in five patients, disappeared in all. Apical systolic murmurs, which were heard in three patients during febrile periods, cleared within two days of treatment. Pleuropericardial friction rubs were heard in two patients over the apex of the heart, and these also disappeared within two days. Enlargement of the heart was present in three patients but was marked in only one. A transient diminution in cardiac size occurred only in the last-mentioned instance during prednisone therapy. Later this patient was found to have a large pericardial effusion at autopsy, as was suspected clinically. The other two patients with enlargement of the heart also had evidence of pericardial disease. Electrocardiographic abnormalities were present in five patients, consisting mainly of T wave and S-T segment changes. The patterns returned to normal during treatment in only two patients.

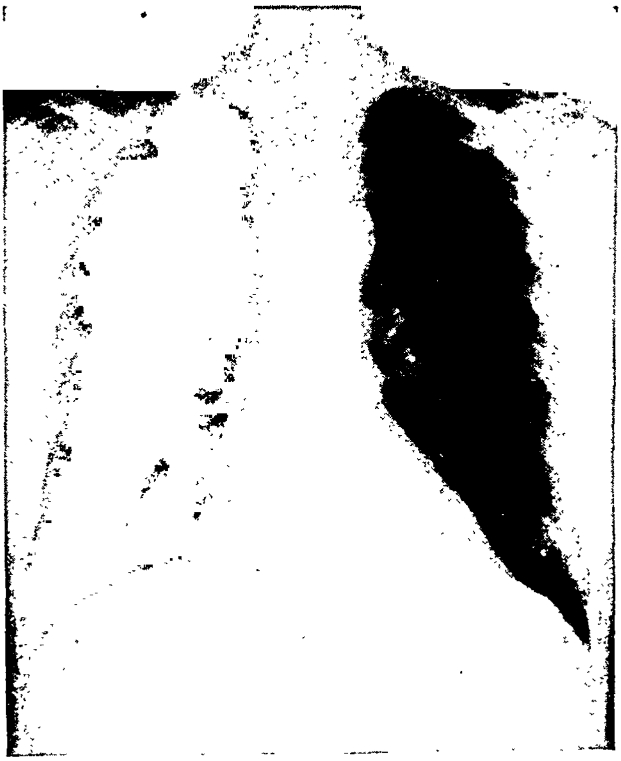

Fig. 3.—Chest x-ray of patient in case 2 taken after 18 days of prednisone therapy, 40 mg. per day.

Effect on Renal Manifestations.—Some evidence of renal abnormality was present in seven patients, but in only four were these findings marked (table 2). Persistent proteinuria (before prednisone therapy) was noted in these four patients; three also had hypoalbuminemia, edema, and azotemia; two had hypertension. Determinations of the daily urine protein excretion in these four patients showed no significant changes during therapy with prednisone in doses up to 30 mg. per day for as long as three months, and there was no indication of improvement in the renal status of any of the patients with severe renal disease.

In one patient proteinuria and cylindruria, and in two hematuria, seen microscopically, appeared during an acute febrile exacerbation of the disease. The proteinuria and hematuria subsided when the toxic state was controlled with prednisone, but no change was noted in the chronic type of hematuria or cylindruria that was unrelated to the febrile episodes. Similarly, azotemia appeared in three patients during acute exacerbations of the disease accompanied by vomiting and dehydration. When fluid balance was restored and prednisone given to control the acute episode, the urea nitrogen level returned to normal in these patients. The three patients with long-standing azotemia showed no improvement when steroid was given.

Prior to treatment, hyponatremia occurred in five patients and hyperkalemia in three, and there were no consistent changes resulting from prednisone therapy, although improvement in these findings did occur in some cases. There was a slight rise in the serum carbon dioxide content in most patients, averaging 3 mEq. per liter, and acidosis, which was present in two patients, improved. Edema was present in three of the patients with severe renal disease at the time prednisone therapy was begun. Weight loss occurred in all three of the edematous patients, averaging 4.2 kg. (9.2 lb.), and a gradual disappearance of the edema was noted in one case. In the two patients with marked albuminuria, hypoalbuminuria, and edema, no significant improvement occurred. The effect of therapy on the serum protein levels will be discussed presently.

Retinopathy was present in three patients, and gradual clearing of the small hemorrhages and exudates occurred in one patient. Another patient had considerable arteriolar narrowing and irregularity, as well as hemorrhages and exudates. These findings were increasing rapidly and marked papilledema appeared before prednisone therapy was begun. No further change in the retinal picture occurred after prednisone therapy was started, although this patient did develop hypertensive encephalopathy. The blood pressure was elevated in three patients with severe renal disease at the time prednisone therapy was begun. No significant changes in blood pressure levels occurred in these or other patients during treatment.

Effect on Gastrointestinal Manifestations.—Nausea, vomiting, dull upper abdominal pain, and epigastric tenderness were present in several patients and responded well to treatment with prednisone (table 2). Hepatomegaly was present in four patients but was not marked in any. Return of the liver to normal size occurred in three patients after two to four weeks of therapy. Icterus associated with marked malaise, nausea, vomiting, epigastric discomfort, and an enlarged, tender liver appeared in one patient immediately before prednisone therapy was begun. The serum bilirubin level rose to 2.6 mg. per 100 cc., alkaline phosphatase rose to 4.0 Bessy-Lowry units, the cephalin flocculation test became strongly positive (3+), and thymol turbidity was 8 units. These findings gradually subsided while the patient received prednisone (30 mg. per day). She left the hospital after three weeks of therapy but continued to take prednisone at home. Upon readmission three weeks later, all liver function tests, including sulfobromophthalein (Bromsulphalein) retention, were within normal limits. The icterus was probably due to an intercurrent, acute, viral hepatitis (other cases of infectious hepatitis appeared in hospital personnel at the same time). Abnormal cephalin flocculation and thymol turbidity were also present in the serum of two other patients, without other evidence of impaired liver function. The thymol turbidity became normal, but a positive (2+) cephalin flocculation reaction persisted after six weeks of therapy with prednisone in both instances. No patient in this series showed a positive serologic test for syphilis.

Effect on Central Nervous System Manifestations.—Headache was present in six patients and was associated with hypertension in three of these (table 2). In the three patients in whom it was not associated with hypertension, headache cleared promptly with prednisone therapy. Seizures occurred in two patients before prednisone was administered. These were associated with loss of consciousness and consisted of a focal onset progressing to generalized clonic and tonic movements. These two patients improved during prednisone therapy, but one required continuation of barbiturates in order to prevent seizures. A third patient developed convulsive seizures during prednisone therapy. She had marked hypertension and increasing retinopathy before this steroid was given, and the seizures seemed to be due to an episode of hypertensive encephalopathy, which subsided during treatment with hypotensive agents.

Mental changes were present in two patients before prednisone therapy; one had marked confusion, impairment of memory, and episodes of disorientation and the other had brief episodes of loss of consciousness, involuntary movements, and loss of ability to concentrate. Both patients showed improvement when given prednisone, although some mental impairment persisted in the former patient. Electroencephalograms were obtained in eight patients in this series and five were found to be abnormal; these consisted of the patients with seizures and those with mental changes. The tests were repeated on four of these patients after six weeks more of prednisone therapy, and no improvement was found in any case.

Effect on Hematological Manifestations.—Leukopenia was present in eight patients, with total white blood cell counts ranging between 2,000 and 4,000 cells per cubic millimeter (table 2). In six of these patients the white blood cell count rose above 5,000 after periods of prednisone therapy ranging between one and six weeks. Eight patients had a definite anemia (hematocrit value below 38%), and the average hematocrit value for the entire group was 32%. Although some rise occurred during therapy in six of these patients, the hematocrit value reached 38% in only three and the average rise in hematocrit value during therapy was 5%. This peak was usually reached after three weeks. In the three patients with renal failure, there was a gradual but progressive fall in hematocrit value during the entire period of hospitalization. None of the patients in this series had a positive Coombs' test or clinical evidence of acute hemolysis.

Effects on Serum Constituents.—All 10 patients in this study had serum albumin levels below 3.5 gm. per 100 cc., and four had serum globulin levels above 3.5 mg. per 100 cc. (table 2). In no case did the levels of the protein fractions return to normal during prednisone therapy, although some changes did occur. The serum cholesterol level had been elevated in two patients who had albuminuria and edema. A rise in serum cholesterol, averaging 79 mg. per 100 cc., occurred in 8 of the 10 patients during prednisone therapy. Similar changes have been noted during prednisone and prednisolone therapy of rheumatoid arthritis.[18] Changes in the nonprotein nitrogen and electrolyte constituents of serum have already been mentioned.

Effect on Over-All Status of Patient.—Most of the patients were started on prednisone therapy at a time when they were acutely ill with symptoms of relapse that followed reduction in dosage of the older steroids. Marked and early symptomatic improvement occurred, therefore, as the systemic manifestations of the illness were controlled by prednisone. When the maintenance dose had been reached, eight of the patients felt that they were stronger, free of annoying minor symptoms, and functionally improved, in contrast to their status on previous therapy. The patients who had had frequent exacerbations of the disease due to escape from steroid suppression were better controlled by prednisone therapy during the period of observation. On the other hand, those patients with serious renal disease showed no improvement in their clinical status or in the results of the tests of renal function that were performed. Similarly, patients with evidence of cardiac involvement due to lupus erythematosus showed no significant improvement. The manifestations of lupus erythematosus that were observed to be refractory to therapy with prednisone are summarized in table 3.

Follow-Up.—Periods of observation have extended for between two and eight months, averaging four months. During this time, two of the patients with severe renal disease died in uremia. The other patients have all maintained whatever improvement occurred after transfer to prednisone therapy.

Side-Effects.—Minor undesirable side-effects were seen in all 10 patients. These included minor mental changes, such as transient euphoria in two and irritability in one patient. Also, facial rounding occurred in all 10, amenorrhea in 3, mild hirsutism in 2, epigastric discomfort in one, and acneform eruption in one. No serious side-effects, however, were observed, and it was not necessary to discontinue use of the drug in any case. It should be mentioned, however, that serious side-effects have been observed with prednisone and prednisolone in the treatment of a series of patients with rheumatoid arthritis.[2] These included the occurrence of peptic ulcer, psychosis, compression fractures of vertebrae, and alteration of glucose tolerance. In these patients with lupus erythematosus, however, gastrointestinal x-rays and glucose tolerance tests were done every six weeks during the period of the study, but no abnormalities were found.

COMMENT

Several comprehensive studies of the effects of cortisone and corticotropin therapy on systemic lupus erythematosus have been published.[3] There has been general agreement concerning the efficacy of these drugs in the treatment of this disease. Fever, arthritis, lymphadenopathy, mucocutaneous manifestations, as well as pulmonary manifestations, have improved with adequate dosage readily. Cardiac abnormalities and hepatosplenomegaly, however, have responded with greater variability. Cortisone or corticotropin administration was accompanied by an increase in white blood cells when leukopenia had occurred and by some correction of the anemia, hypoalbuminemia, hyperglobulinemia, and increased erythrocyte sedimentation rate. Disappearance of urinary abnormalities was observed in one series [3b] but not in another.[3a] Harvey and associates [3c] have reported decrease in albuminuria or hematuria in about 50% of cases, frequently associated with subsidence of an acute phase of the disease. Little improvement was noted in patients with the nephrotic syndrome.[3a] Positive cephalin flocculation tests and thymol turbidity tests have returned to normal and reduction in sulfobromophthalein retention has been noted. Dubois and others [3a] reported disappearance of L. E. cells from peripheral blood during remission, but this was not confirmed by Soffer and collaborators.[4] Harvey noted disappearance of L. E. cells in only 5 of 46 cases, and these 5 exhibited few L. E. cells prior to steroid therapy.

TABLE 3.—*Manifestations of Systemic Lupus Erythematosus Refractory to Therapy*

Systemic	Renal	Pulmonary and Pleural	Cardiac	Central Nervous System
L. E. phenomenon Anemia Elevated erythrocyte sedimentation rate Low serum albumin Adenopathy	Edema Hypertension Retinopathy Proteinuria Hematuria Cylindruria Azotemia Electrolyte abnormalities	Rales often diminish but do not usually disappear	Enlarged heart Abnormal electrocardiogram	Abnormal electroencephalogram

Cortisone and corticotropin therapy in systemic lupus erythematosus has been frequently associated with complications. Besides the usual Cushing-like changes, cardiovascular complications have been present, especially hypertension, fluid retention, and congestive heart failure. Some form of mental aberration has been noted in from one-half to two-thirds of the cases, and psychoses have been seen with some frequency. Convulsions occurring in the course of this disease may at times be attributable to cortisone therapy. However, most of the side-effects resulting from therapy have been reversible and are alleviated by reduction of the dose or discontinuation of use of the drug. The over-all effect of cortisone and corticotropin on prognosis and prolongation of life is believed by Dubois and associates to be slight. However, Haserick [5] states that these drugs not only have dramatic effect in the acute disease but actually prolong life. At the time of their review, Harvey and associates believed the data on this point insufficient to permit a valid conclusion.

This study of the effects of prednisone and prednisolone in the treatment of systemic lupus erythematosus is based on 10 cases followed for an average period of only four months, and the observations made must be viewed with these limitations in mind. The results indicate that the effects and limitations of prednisone closely resemble those of cortisone, hydrocortisone, and corticotropin. These agents are capable of suppressing the acute toxic manifestations of the disease, including fever, arthritis, malaise, and anorexia, and can tide a patient over a severe exacerbation. In addition, they may suppress to a varying degree, and usually incompletely, pulmonary, pleural, cardiac, and central nervous system manifestations of the disease. Renal pathology in particular does not seem to be significantly influenced by therapy with either the new or the older steroids.

Prednisone and prednisolone have been found to be approximately four times as potent as cortisone and hydrocortisone in controlling these steroid-sensitive manifestations of lupus erythematosus, thus resembling the comparative potency found in the treatment of rheumatoid arthritis.[6] Dose for dose, however, there is a comparable incidence of undesirable side-effects, with the notable exception of sodium and water retention and the production of hypopotassemia. The lack of salt-retaining effect indicates that prednisone and prednisolone should have a significant advantage over the other steroids in the treatment of patients with lupus erythematosus, who have cardiac or renal involvement, since these drugs will not accentuate a tendency toward fluid retention or electrolyte imbalance. The three patients with edema due to renal disease all lost weight, and one lost the edema entirely when transferred to prednisone, although there was no significant effect on the underlying renal disease. Further, the fact that a low-salt diet is not necessary and supplementary potassium need not be given when these drugs are administered constitutes an additional advantage.

SUMMARY AND CONCLUSIONS

In a study of 10 patients with lupus erythematosus followed for an average period of four months, prednisone and prednisolone have been found to be potent suppressive agents. They are capable of diminishing the fever, chills, malaise, anorexia, arthritis, rash, mucous membrane lesions, cough, pleuritic and precordial pain, chest wall tenderness, pleural and pericardial friction rubs, pulmonary rales, abdominal pain and tenderness, headache, convulsive seizures, leukopenia, elevated sedimentation rate, and C-reactive protein. Renal abnormalities, including proteinuria, hematuria, seen microscopically, cylindruria, and azotemia, improved only in those instances in which the abnormalities had increased or appeared during an acute exacerbation of the disease, usually accompanied by fever and dehydration. Serious renal disease in these patients was not influenced by these drugs, and two patients died in uremia. No significant alterations of blood pressure were observed. Edema was noted to gradually diminish during prednisone therapy. Leukopenia improved in most instances, but anemia did not, and alterations in serum albumin and globulin levels were only slight. These steroids were found to be approximately four times as potent as cortisone and hydrocortisone and did not cause salt or water retention or hypopotassemia. Minor undesirable side-effects have appeared.

In general, the effectiveness and limitations of prednisone and prednisolone in the treatment of systemic lupus erythematosus parallel closely those of cortisone and corticotropin, with the exception that the new steroids do not cause sodium and water retention or potassium loss when administered in moderate therapeutic doses.

POSTURE AND CERVICOBRACHIAL PAIN SYNDROMES

Donald A. Johnson, M.D., Ph.D., Memphis, Tenn.

The accurate diagnosis and effective treatment of disabilities manifest by cervicobrachial pain and paresthesias is difficult. The difficulty has been increased by the myriad of reports dealing with cervicobrachial syndromes, because of a tendency to regard each of them as a specific clinical entity. Lack of notable success with specific treatment as in the scalenus anticus syndrome has tended to discredit the syndrome without otherwise accounting for the patient's disability. To fill this void the criteria for a diagnosis of a protruded cervical intervertebral disk are at times stretched beyond their just limits or a functional etiology is invoked to explain such symptoms. To the confusion of examiners, specificity of name in cervicobrachial syndromes is not matched by a specificity of either symptoms or signs.

Many of the cervicobrachial syndromes regularly listed in diagnostic classifications are not clinical entities but rather are isolated aspects of a single clinical problem. The common factor in a variety of cervicobrachial syndromes is posture. Postural factors are the commonest primary cause of disability of this type, and the correction of postural stress will contribute to the relief of symptoms. Naffziger and Grant,[1] Gage and Parnell,[2] Hansson,[3] Freiberg,[4] DePalma,[5] and others have written of the importance of postural factors in the scalenus anticus syndrome. Falconer and Weddell[6] stated that postural changes without anatomic defect precipitated neurovascular symptoms in their costoclavicular syndrome. McGowen and Velinsky[7] pointed out that exercises designed to strengthen the trapezius and levator scapulae muscles were curative in the same type of problem. Michele[8] indicated that postural changes with round shoulderness and drooping of the shoulder girdle were the primary underlying factors in the scapulocostal syndrome. Walshe and co-workers[9] indicated that posture was a primary factor in first rib syndromes. These observations are scattered thru a voluminous literature and have not received the recognition they deserve except by Haggart[10] in 1948, who emphasized the value of conservative treatment. The importance of posture in a variety of less well known and primarily orthopedic cervicobrachial syndromes is generally acknowledged. In an effort to develop a more practicable clinical approach to the problem of cervicobrachial pain and paresthesias, it seems justifiable to define a diagnostic category based on the factor common to so many cervicobrachial syndromes, i. e., the postural factor. Postural myoneuralgia is a descriptive term for this category.

SYMPTOMS

Pain and/or paresthesias involving a cervicobrachial distribution and due to postural stress are not peculiar to individuals with any particular physical habitus. Oc-

cupational factors are very important contributing causes to the onset of symptoms. Onset following trauma is very common, or after unusual physical exertion as occurred so often in service personnel during the war. It is common in middle-aged women, but it is also seen in young girls, often during or just after pregnancy, and it is not rare in men. The principal complaint may be either pain or paresthesias; often both are present. These are usually referred to the upper extremity but may involve primarily the anterior chest wall, the shoulder, the interscapular area, the midcervical or cervicodorsal area of the spine, the midthoracic or thoracolumbar area of the spine, or the occipital area of the skull. The discomfort is usually worse at night, often awaking the patient from sleep, and it is usually present on awakening in the morning. A history of sleeping with the arms hyperabducted is occasionally of significance. The complaint may be unilateral or bilateral. Precordial pain may be the principal complaint. Interscapular pain may be present alone, or any combination of the complaints mentioned above. Peripheral radiation into the upper extremity may occur along either the ulnar or radial border of the arm and forearm and may involve the entire arm, the hands alone, or part of the hand. The peripheral pattern of pain and paresthesias may suggest a dermatome or root distribution. Activity involving elevation of the upper extremities usually makes the discomfort worse. Spontaneous remissions are common.

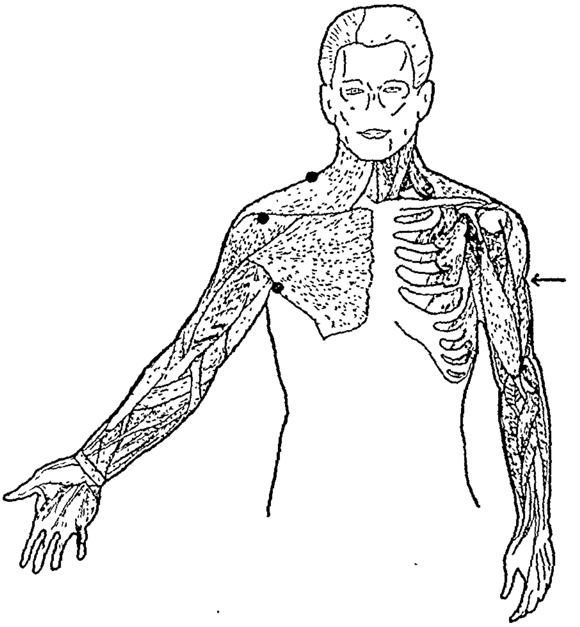

Fig. 1.—Common anterior areas of point tenderness (muscle).

Though such a history is characteristic of a postural disorder, it is obviously not specific and will occasionally be elicited in conditions other than that under primary consideration in this paper. These symptoms, however, include a variety of syndromes in which posture is of primary significance.

SIGNS

A tilt of the shoulder girdle is often present. One shoulder may be carried lower than the other when the patient is observed in a relaxed sitting position. The higher shoulder is usually, but not always, on the painful side. Not infrequently the patient will shift his posture so that a shoulder noted to be elevated at one time during examination will be found to be lower than its opposite a short time later. In relatively acute cases the shoulders are usually level.

Neurological examination often reveals hypesthesia and hypalgesia over a distribution suggestive of a dermatome pattern. An ulnar distribution is most common. There may be objective weakness of the hand or forearm muscles and occasionally atrophy of muscle groups in the hand, the thenar eminence, or the interossei. Early morning swelling of the hands may be noted by the patient.

Muscle tenderness to point pressure is almost always present in some part or all of the pattern shown in figures 1 and 2. There is little rationale to description of isolated pectoral tenderness as a pectoral syndrome or of upper and lower trapezius syndromes depending on the location of point tenderness over that muscle. They are all part of a postural disorder, and multiple tender areas are usually found if carefully sought. Tenderness over the scalenus anticus muscle is part of the pattern. This is muscle tenderness, and the diagrams are of no significance except to indicate convenient points at which to test individual muscles that are usually tender. Pressure over the coracoid process tests the pectoralis minor. The muscle tenderness may be unilateral or bilateral; it is usually worse on the side of the principal complaint. Holden, Murphy, and Portmann [11] cautioned that one must be careful to differentiate and not section the scalenus anticus muscle of patients who have what they called a "diffuse myositis" involving the trapezius,

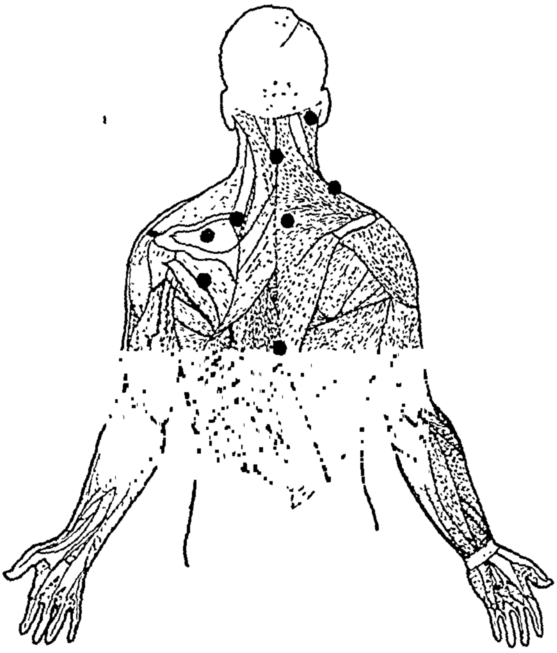

Fig. 2.—Common posterior areas of point tenderness (muscle).

rhomboid, and pectoral muscles. Such a "myositis" is a feature of the postural disorder, and a careful search for it should be a part of every examination. One or several points of tenderness are equally significant.

Reduction of the radial pulse amplitude to palpation and a bruit on auscultation over the subclavian artery are usually present when the arm is abducted to right angles with the thorax with the elbow flexed 90 degrees. The bruit may be unilateral or bilateral and is usually more prominent on the side of the principal complaints. It is of the utmost importance that auscultation be carried out, as a loud bruit may be produced by abduction of the arm without palpable change in the radial pulse. Eaton[12] has emphasized that the vascular tests and maneuvers associated with various cervicobrachial syndromes are not specific and that many of them cannot be accurately reproduced from one patient to the next. Wright[13] and others have found a high incidence of radial pulse obliteration with more extreme hyperabduction of the arm in normal individuals. It is well, therefore, to use this single maneuver and to evaluate it carefully in the light of the history and the other physical signs. One cannot deduce compression at any particular point when a bruit is elicited, but it does indicate that in a given patient the neurovascular bundle is easily compressed by elevation of the arms. Rarely, a bruit is present even when the patient's arms are relaxed at the side of the body. Remarkably enough, the bruit often disappears when the patient is relieved of his discomfort; as often, its intensity is considerably reduced on recovery though the bruit is not eliminated, and, not infrequently, it is unchanged despite clinical recovery. This clearly demonstrates its lack of specific significance in relation to the clinical complaint.

X-ray examination of the cervical spine and thoracic outlet will either show no abnormalities or show straightening of the normal cervical curve. The latter does not indicate a protruded cervical disk or foraminal compression, but only muscle spasm of nonspecific origin.

DIFFERENTIAL DIAGNOSIS

The differential diagnosis need not be discussed at length, inasmuch as all of the conditions to be differentiated from a postural disorder have been discussed at length by many writers. It is ordinarily not difficult to differentiate this syndrome from a cervical intervertebral disk protrusion, but occasionally it cannot be done on clinical grounds and myelography will be necessary. Median nerve compression within the carpal tunnel will not cause confusion if one is familiar with that syndrome. Periarthritis of the shoulder and tendonitis must always be excluded. Arthritic changes in the cervical spine do not exclude a postural disorder, nor does the presence of cervical ribs or other anomalies, though they must be evaluated individually.

The diagnosis of a postural disorder rests on (1) a characteristic history, (2) shoulder girdle tilt, (3) all or some part of the characteristic pattern of muscle tenderness to point pressure, and (4) a bruit over the subclavian artery when the arm is abducted. One or more of these elements is often lacking, and none is specific.

It is likely that patients with postural stress causing signs and symptoms consistent with the pattern above constitute the largest group among those with cervicobrachial complaints. It would include many cases that in past years were diagnosed as due to the scalenus anticus syndrome. A scalenus anticus syndrome requiring surgery is not common, and consideration of postural myoneuralgia in differential diagnosis will improve the mediocre surgical statistics dealing with scalenus section.[14] It will be apparent to all familiar with the history of the scalenus anticus syndrome that consideration of this postural disorder is of extreme importance in the evaluation of such procedures as resection of the clavicle for cervicobrachial pain and the recent extension of the indications for median nerve decompression to this same type of disorder.

The acroparesthesia syndrome of Schultz will come within the category of the postural disorder, and it is amenable to treatment. The same is true of the brachialgia statica paresthetica syndrome of Wartenberg and the so-called brachial neuritis of pregnancy. The costoclavicular compression syndrome is part of the same clinical entity, a postural disorder, as well as "normal" and some "abnormal" first rib syndromes. The scapulocostal syndrome of Michele is not an entity in itself, but part of this same clinical pattern. The problem of differential diagnosis will be simplified by inclusion of these syndromes in one diagnostic category. Other less familiar

syndromes also are clearly a part of a postural disorder and recognized individually as such by the orthopedists who see them most commonly, though their designation as specific syndromes persists by usage.

TREATMENT

To recommend a simple exercise program as treatment for what has been regarded as a variety of disorders may seem like oversimplification. There is ample support for this position, however, for scattered through the literature one finds, repeatedly, the opinion that a simple exercise program is probably the most important factor in treatment of various cerevicobrachial syndromes. This aspect of treatment is emphasized here and extended to cover a larger diagnostic category.

The average patient requires only office instruction in exercises and posture and can carry out a satisfactory corrective program at home. In severe and protracted cases hospitalization may be indicated to afford continuous observation and support of the patient as well as the cooperation of the physical therapy section. The patient should be instructed to carry out three simple exercises, and these should be demonstrated to the patient by the physician. The first exercise consists of bracing the shoulders back as though to approximate the medial scapular borders in the midline (fig. 3*A*). The second consists of bracing the shoulders upward as though attempting to touch the shoulders to the ears (fig. 3*B*). The third is a "push-out," done by standing about 2 ft. away from and facing into a corner with one hand on each wall at shoulder level (fig. 3*C*). It will be found that many patients cannot touch the wall with their chest in this latter maneuver and will require several days of exercises before they can do so. Indeed, this is so common that the maneuver can almost be used as a diagnostic test, inasmuch as pectoral shortening is usually present. The exercises stretch the pectoral muscles and strengthen the upper trapezius, rhomboids, levator scapulas, and serratus muscles. Though this group of exercises is open to some objections from the theoretical standpoint, it is simple, easy to remember, and, most important of all, effective.

Each exercise should be done 5 to 10 times hourly through the day if the patient's physical status and daily activities permit. Patients should be informed that the first few days of exercises may make them somewhat more uncomfortable temporarily. They must be admonished to assume an erect posture at all times between exercises. Resumption of old postural attitudes between the exercise periods is the commonest cause of failure to improve. Improvement is usually marked within two weeks, and failure to improve after three weeks calls for a careful review of the entire problem.

Cervical traction is helpful at times, to help relax tight muscles, but it is not remedial and should not be considered a primary method of treatment. Heat and massage are helpful, and mild sedation and analgesics may be helpful in the early phase of treatment.

SUMMARY

A revised concept of cervicobrachial pain and paresthesia problems includes a larger number of these problems under the diagnostic classification of postural myoneuralgia. Such a concept will simplify the diagnosis of this type of disorder, improve the selection of patients in whom surgical intervention may be indicated, and provide effective and simple treatment for some patients who would otherwise be treated inappropriately or be relegated to a diagnostic category that implies that no effective treatment is available.

USE OF RESERPINE IN PSYCHOGENIC RHEUMATISM, OSTEOARTHRITIS, AND RHEUMATOID ARTHRITIS

A PRELIMINARY REPORT

Harry Bartfeld, M.D., New York

The various arthritic diseases, especially those involving the periarticular structures and more definitely the muscles and associated structures, are subject to, and generally exacerbated by, emotional stimuli. This is well illustrated in works on psychosomatic medicine. In this respect the American Rheumatism Association has recognized such a diagnosis under the heading "psychogenic fibrositis or rheumatism" or, better, "psychoneurotic musculo-skeletal complaints." The incidence is not small. In one study of 500 consecutive civilian patients,[1] the diagnosis of psychogenic rheumatism was made in 13.4%, osteoarthritis in 25%, rheumatoid arthritis in 20.4%, and primary fibrositis in 18.2%.

The symptoms these patients have are in the nature of fibromyalgia, with areas of tenderness over muscle and bone; pain, stiffness, and limitation of motion of the muscles and joints; and subjective feelings of swelling. It has further been shown that in musculoskeletal disorders on a psychosomatic basis[2] there are "characteristic areas of tenderness—the dorsal radial forearms, upper part of the trapezius muscle at the shoulder and posterior neck regions, lateral upper arms, pectoral areas, low back, thigh, lower third of leg and tarsal areas. The degree of moderately firm pressure needed to elicit this tenderness varies but is never sufficient to be painful to the normal individual." In addition the symptoms of primary organic arthritic disorders may be aggravated by

[2] Irvine, J. H.: Psychosomatic Diagnosis of Chronic Musculoskeletal Pain, read before the Clinical Meeting of the New York State Rheumatism Association, New York, April 16, 1952.

emotional stimuli. It has been suggested[3] "that rheumatoid arthritis is an organic psychosomatic disease with an added genetic factor and that patients having the disease show emotional inhibition with obsessional trends." Most authorities, however, do not agree with this but do feel that psychosomatic emotional disturbances may be associated with exacerbations.

It has also been reported that fibromyalgia in association with neurotic emotional states is common in 70% of patients having osteoarthritis.[2] This is well illustrated in two patients of similar stature showing typical osteoarthritic changes in the spine on x-ray examination, only one of whom has symptoms of low back pain and spasm of muscles. Sometimes a psychiatric history will reveal emotional difficulties in the patient presenting symptoms. The psychopathology of these fibromyalgic phenomena has been summed up as follows: There is (1) a psychoneurotic disposition, (2) an excitatory emotional conflict, and (3) a restriction of outward expression of the conflict. "Smouldering resentment has been stated to be the common basic psychopathology in psychogenic rheumatism."[4] The psychophysiological mechanisms involved have not been fully identified, but it has been suggested that emotions affect the autonomic nervous system either directly or through the medium of the endocrine system and thereby produce increased muscle tension, vasospasm, and metabolic changes in organs and in the musculoskeletal system.[5] In this respect it has been noted that corticotropin (ACTH) or cortisone may relieve these fibromyalgias.

In the past year there has appeared a series of reports dealing with alkaloids of Rauwolfia serpentina, especially reserpine. Pharmacological studies[6] revealed an action on the autonomic nervous system, possibly by a partial suppression of activity of the hypothalamus. In this respect it has been established that the emotional response is mediated through the hypothalamic centers. It was concluded that reserpine exerts a calming and sedative action in a wide variety of animal species. The sedation, reduced emotional response, peripheral autonomic alterations, and circulatory changes are due to an alteration of sympathetic-parasympathetic balance by partial suppression of sympathetic predominance at the hypothalamic level.

Clinical investigations demonstrated that reserpine had a sedative and tranquilizing effect and reduced the emotional and mental tensions of geriatric patients.[7] Such actions would be of value in relieving the causative stimuli perpetuating the fibromyalgias of psychogenic rheumatism and that component of the symptoms of osteoarthritis due to psychosomatic stimuli. In addition,[8] it was reported that the drug reduced anxiety and obsessive-compulsive drives and could overcome excessive inhibition and reticence. In the beginning of this paper is a quotation[3] to the effect that such neurotic traits distinguished the personality complex of patients having rheumatoid arthritis. Again assuming that such stimuli may exacerbate some musculoskeletal symptoms of rheumatoid arthritis, the action of reserpine in reducing the severity of these neurotic characteristics would be most welcome.

SELECTION OF PATIENTS AND INITIAL THERAPY

In view of these reports it appeared that the effect of reserpine on patients having rheumatism and arthritis should be investigated. In the beginning, it was intended for use only in cases of "pure" psychogenic rheumatism, but, in recognition of the importance of psychosomatic musculoskeletal phenomena on some of the symptoms and course of the other arthritides, it was decided to include these. It has been stated,[5] "Most physicians themselves have experienced muscular aching and fatigue in one or another region following periods of prolonged emotional tension."

The cases were divided as follows: psychogenic rheumatism, 7; osteoarthritis, 16; rheumatoid arthritis, 4; and osteoarthritis together with rheumatoid arthritis, with the former predominating, 3. For the most part the patients were initially given a 0.1 mg. tablet of reserpine (Serpasil) twice daily (preferably one tablet at bedtime and one tablet on arising). When there was no response after one or two weeks, the dose was increased to 0.1 mg. three or four times daily and in some cases to 0.25 mg. tablets twice daily. In patients who showed a response, some were given a placebo (identical in appearance to the reserpine tablets) for a time.

RESULTS AND FURTHER THERAPY

Psychogenic Rheumatism.—In the series of cases of psychogenic rheumatism, five of the seven patients demonstrated beneficial effects, one had no response, and one showed an equivocal response. Among the five showing a good response was a man who had pain in the hands and back that had not improved with administration of acetylsalicylic acid. He was given reserpine, 0.1 mg. twice daily, for one week, followed by the same dose three times a day for a second week, when he reported that his hands were better and not as stiff as before. He was then given placebo tablets three times daily for two weeks; during the first week he continued to feel well but in the second week he again had pain and stiffness in the hands and neck and was nervous. At this time he was treated with reserpine, 0.25 mg. twice daily, and a week later said that he felt good, that his hands were less swollen, and that his back was better.

In a similar case another man had had low back pain for three years. Previously he had been given courses of phenylbutazone, cortisone in doses of 100 mg. a day, phenobarbital in doses of 0.03 gm. three times daily, and acetylsalicylic acid in doses of 0.3 gm. four times a day, with no relief. When he was first treated with reserpine, he complained of pain in the back, neck, and arms, with muscle tenderness. He was given reserpine, 0.1 mg. twice a day for one week, and the following two weeks the same dose three times a day with no effect. When the dose was finally increased to 0.25 mg. twice a day, he reported that he felt better and that muscle pain was present but it was less intense. He was then given placebo tablets twice a day and said that he felt so bad that he had to stay in bed a few days. On the other hand, a young man with typical tender muscles who had been treated at the mental hygiene clinic but had shown no response to aspirin or phenobarbital showed no response to reserpine administered in doses of 0.1 mg. twice and three times daily. Perhaps the dosage should have been increased.

Osteoarthritis.—Only 5 of the 16 patients with osteoarthritis showed an adequate result. One such patient was a woman who was very nervous and complained of pain and stiffness of shoulders and neck. When she was given reserpine, 0.1 mg. twice daily, for one week, she reported that she felt better and her pains were gone. She was then given placebo tablets twice daily for two weeks; during the first week she continued to feel fine, but during the second week her back became extremely painful and she could not bend over. At this time she was again given reserpine, 0.1 mg. twice a day, and a week later said she was 80% better and that she could bend down and kneel. The following week with the same dose her improvement continued. She said it was "the best medicine" she had taken and she "could sleep nights." Another patient in this group showed a response during the first two weeks of receiving reserpine; when he was given a placebo for one week his symptoms of ankle and arm pain returned. Therapy was again instituted with reserpine, and his symptoms abated; these came back when he was again receiving placebo therapy.

In evaluating results, one must remember the desire of patients to recover, especially when they know they are receiving a new drug. Such a patient was a woman who had had osteoarthritis and Parkinsonism for four years. When treatment with reserpine was started, she had been receiving hydrocortisone, which had not relieved her complaints of stiffness and pain in the left hip and of gross tremor of her hands. After a week of reserpine therapy in doses of 0.1 mg. twice a day, she said she could use her right arm more than before, although the pain in her hip was still present. She was then given placebo tablets and felt so well with them that she continued taking them for four more weeks. Not only did her rheumatism improve but she said most of the tremor of her hands had disappeared and "she was able to sign her relief check." After five weeks of placebo therapy, some of the pain in her hip had returned but the effect on the Parkinsonism continued.

Rheumatoid Arthritis.—In the four cases of rheumatoid arthritis, two patients showed no effect. In one patient who had had the disease for 10 years, there was only a mild beneficial result. In the fourth case, a young man with early rheumatoid arthritis showed a good response. This patient had typical swollen fusiform proximal interphalangeal and swollen metacarpophalangeal joints and could not close his hands. There had been a moderate response to corticotropin and also to cortisone in doses of 50 mg. a day. After one week of reserpine therapy in doses of 0.1 mg. twice a day, he said he slept better and felt better and could close his hands more easily. He was then given placebo tablets twice a day and reported that his hands were stiff and painful and he did not sleep well. When he was again given reserpine in doses of 0.1 mg. three times a day, he said he could close his hands more fully and they were not stiff and he felt he could do more than when he was taking cortisone. He continued on reserpine therapy, 0.25 mg. twice daily, for three weeks. During the first week he had a tooth extracted and he reported that his hands were stiff; the second week was a rainy one and the stiffness continued. During the third week his hands were again limber and pained him only occasionally. This patient is a homosexual and has most of the psychogenic stigmas reported in some cases of rheumatoid arthritis as referred to earlier in this report.[3]

Mixed Rheumatism.—In the three cases of rheumatoid arthritis and osteoarthritis with the latter predominating, two patients showed mild beneficial results with reserpine, one patient reporting that she felt quieter, that her spirits were better, and that she was not as stiff as before. The other said that she slept better, did not have the dizzy spells she had had previously, and her left knee was stronger; however, her right wrist and back were still painful and stiff. The third patient reported that, after two weeks of therapy with reserpine, 0.1 mg. twice a day, she felt better and walked more easily. She was kept on the placebo regimen for four weeks, and her improvement held.

COMMENT

It appears that reserpine is of value in the treatment of psychogenic rheumatism and of some aid in the other arthritides, although not of equal efficacy. It must be pointed out that, in this clinical trial, the drug was used alone to evaluate its actual effect on musculoskeletal complaints. Certainly in the treatment of these diseases additional drugs, such as analgesics, antispasmodics, and hormones; and gold therapy; psychotherapy; and physiotherapy should be continued or instituted where necessary. The manner of action of this drug may be readily explained by its effect at the hypothalamic level in inhibiting those phenomena due to emotional and psychogenic strain that serve to propagate neurogenic and vasomotor stimuli, that in turn cause muscle spasm and other changes in muscle, which in turn cause local tenderness, pain, and stiffness. Thus the attack on these diseases should be threefold: (1) use of analgesic drugs, anti-inflammatory hormones, gold therapy, and physiotherapy, agents which act directly or through other mechanisms on the local phenomena due to organic or psychogenic causes; (2) use of reserpine to minimize those psychogenic stimuli that cause musculoskeletal complaints in pure psychogenic rheumatism and that aggravate the primary organic arthritides; and (3) use of psychotherapy where needed.

The sense of well-being and serenity and general uplifting of spirit due to reserpine may also help in giving the patient a better and more stable approach to his disease, to wit, the symptoms are not as intense or as important. In this respect phenobarbital has also been used in the treatment of the psychosomatic aspects of rheumatism. It is suggested that reserpine be combined with the anti-inflammatory hormones to decrease the hypertension and euphoria that the latter may cause.

SUMMARY

Reserpine (Serpasil) temporarily relieved the musculoskeletal complaints in five of seven cases of psychogenic rheumatism. Reserpine temporarily relieved the musculoskeletal complaints in 5 of 16 patients having osteoarthritis and in 1 of 4 patients with rheumatoid arthritis. In three cases of rheumatoid arthritis and osteoarthritis, the latter predominating, results were mildly beneficial. In some patients the drug is a useful adjunct to the symptomatic treatment of the various arthritides, but no curative effects are claimed. In pure psychogenic rheumatism it should be combined with psychotherapy and analgesic drugs. In the primary organic arthritides it should be added to the analgesic, the anti-inflammatory, and/or gold drugs routinely used, since it may minimize, where they exist, those psychogenic stimuli that cause musculoskeletal complaints that in turn aggravate the primary organic diseases. This study in a limited series of cases indicates that further investigation of reserpine in psychogenic rheumatism and neuroses associated with other arthritides is warranted.

TREATMENT OF HYPERTENSIVE PATIENTS WITH RAUWOLFIA COMPOUNDS AND RESERPINE

DEPRESSIVE AND PSYCHOTIC CHANGES

Irving Kass, M.D.
and
Earl C. Brown, Ph.D., Wadsworth, Kan.

Recently Freis [1] described five cases in which mental depression was observed in hypertensive patients treated with reserpine (Serpasil). The purpose of this report is to describe four more hypertensive patients, two in detail, who were treated with a Rauwolfia alkaloid or reserpine. Mental depression was observed in three of the patients, whereas in the fourth case the diagnosis was a psychotic reaction.

REPORT OF CASES

Case 1.—A 54-year-old married white woman, a veteran, was admitted to the hospital on Nov. 12, 1954, for evaluation of her hypertension and depressive reaction. During a routine physical examination in 1944, she had been found to have hypertension and since then had been treated with cortical depressants such as phenobarbital. In May, 1954, she had been placed on therapy with reserpine, 0.25 mg. four times a day. During the summer she had noticed considerable nasal stuffiness. Her mean blood pressure was 160/105 mm. Hg, and the pulse rate was 60 beats per minute. Although her history revealed a cyclothymic personality with primarily depressive swings of varied intensity, for the first time the patient was deeply disturbed, not only by the depth of her depression but with the fact that she had strange irrepressible homicidal impulses toward a member of her family. Unnerved by these thoughts, she feared impending insanity.

With the exception of a slightly enlarged thyroid, there were no unusual or significant clinical findings. The eyegrounds showed no arteriosclerotic changes. Laboratory results were as follows: white blood cell count, 6,200 per cubic millimeter; hemoglobin level, 15.5 gm. per 100 cc.; sedimentation rate 4 mm. per hour; and hematocrit 49%. The specific gravity of the urine was 1.004, and it contained no albumin or sugar; results of microscopic examination of the urinary sediment were likewise negative. Phenolsulfonphthalein studies showed a 46% excretion in two hours, but only a trace of the dye was detected in the first 15-minute urine specimen. The nonprotein nitrogen level was 27.6 mg., the urea nitrogen level 13.2 mg., the glucose level 90 mg., and the serum bilirubin level 0.7 mg. per 100 cc. The serum amylase content was 160 Somogyi units and the total cholesterol content 255 mg. per 100 cc., with cholesterol esters 61%, calcium 5.5 mEq. per liter, inorganic phosphorus 4.0 mg. per 100 cc., and alkaline phosphatase 2.1 Bodansky units. The serum protein-bound iodine level was 2.8 mcg. per 100 cc. (normal 3.5 to 8.0 mcg. per 100 cc.). The iodine diagnostic study of thyroid function showed 26% uptake, which is within normal limits. The electrocardiogram was within normal limits, as were roentgenograms of the chest and of the upper gastrointestinal tract.

On Nov. 13 the reserpine therapy was stopped. The patient was discharged on Nov. 20 and examined at weekly intervals as an outpatient. The therapy was fundamentally a supportive type of psychotherapy, which included no analytic techniques. On Dec. 23 the patient spontaneously reported that she was much improved and subsequent interviews supported her statement.

In summary, this was a case of mental depression that we feel can be attributed to the use of reserpine. A review of the patient's history suggested a premorbid personality pattern that appeared to have been accentuated by the toxic reaction to the drug. In our experience, we have never observed a case of mental depression that cleared as quickly as did this patient's reaction. It is to be observed that a plateau of maximum improvement was noticed about four weeks following the discontinuance of the drug. This correlates well with the clinical studies, which show that the pharmacological effects of reserpine continue for that long a period after the cessation of therapy.

Case 2.—A 66-year-old white male, a World War I veteran, was admitted to the medical service for evaluation of his mental status. He had been first seen in April, 1951, because of retrosternal pain. At that time, his blood pressure was 200/100 mm. Hg and the electrocardiogram was within normal limits. The total cholesterol level was 410 mg. per 100 cc., and the specific gravity of urine was 1.020.

On July 9, 1954, the patient had been again admitted to the hospital for treatment of high blood pressure, nervousness, and a tremor localized in the right arm. The blood pressure was 180/100 mm. Hg. The heart was then clinically enlarged to the left, which was confirmed by both the electrocardiographic and

[1] Freis, E. D.: Mental Depression in Hypertensive Patients Treated for Long Periods with Large Doses of Reserpine, New England J. Med. 251: 1006-1008, 1954.

x-ray findings. The specific gravity of the urine was 1.017 and the nonprotein nitrogen level 44.3 mg. per 100 cc. The patient was seen by the neurologist, who felt that he had generalized arteriosclerosis and that the symptom complex was probably consistent with paralysis agitans of the right upper extremity. The ophthalmologist noticed that the superior and inferior temporal arteries in the right retina had a silver-wire appearance. On July 28, 1954, he was placed on therapy with reserpine in a dose of 0.25 mg. four times a day and trihexyphenidyl therapy in a dose of 2 mg. four times a day. He was discharged from the hospital Aug. 26, 1954. On Sept. 4, 1954, the family physician stopped the reserpine therapy and gave the patient a Rauwolfia alkaloid (Raudixin), 50 mg. three times a day. It was during September, 1954, that the patient's wife noticed a change in his mental attitude.

On Jan. 7, 1955, the patient was again admitted to this facility with an acute psychotic reaction. He was hallucinating, had paranoid ideas of reference, and appeared disoriented in all three spheres. His blood pressure was 180/70 mm. Hg. The heart rate was 95. Funduscopic findings continued unchanged, and the results of neurological examination were now completely normal. The electrocardiogram was within normal limits. An electroencephalogram done on Jan. 10 showed a possible diffuse organic brain dysfunction with probably a few more electrical irregularities in the right temporal area. A second electroencephalogram on Jan. 20 showed no change when compared with the initial examination. A spinal tap on Jan. 12 revealed a normal pressure, clear fluid with no cells, a sugar content of 85 mg. per 100 cc., chloride content of 740 mg. per 100 cc., and a total protein level of 150 mg. per 100 cc. Colloidal gold curves and serologic studies showed no abnormalities. A repeat spinal tap on Jan. 20 showed a lowering of the total protein level to 118 mg. per 100 cc. The leukocyte count was 6,000 per cubic millimeter, hemoglobin level 14.3 gm. per 100 cc., sedimentation rate 11 mm. per hour, and hematocrit 48%. The nonprotein nitrogen level was 34.8 mg. per 100 cc., total cholesterol level 210 mg. per 100 cc., and cholesterol esters level 71%. Results of a cold agglutination test and heterophile antibody study were negative. The chest film showed some prominence of the left ventricle. The skull films, however, were normal.

Clinical Course.—As a result of our previous experience, it was felt that the patient might have a toxic psychosis secondary to the use of a Rauwolfia compound. The Rauwolfia therapy was discontinued, and during the period of hospital observation no medicaments were used. He was seen by one of us (E. C. B.) at weekly intervals, and the following notes were made about the changes in his mental status. When first seen on Jan. 11, 1955, the patient was in cuff restraints and he demonstrated little comprehension of the examiner's questions. On occasions, his intended responses were apparently lost in the maze of ongoing ideation, the content of which was predominantly paranoid in nature. The initial impression was a brain syndrome of unknown cause with a psychotic reaction manifested by confusion and delirium, with an impaired awareness of surroundings and higher intellectual functions, probable hallucinations, persecutory delusions, and agitation.

At the time of the first revaluation on Jan. 18, the patient showed some clearing. A cuff restraint was attached to the bed, and the patient stated that he "asked for it" periodically, especially at night. In this and other ways he demonstrated some insight into the fact that he was subject to confusion and subsequent unpredictable behavior. On the occasion of the second revaluation on Jan. 25 no cuff restraint was observed. The patient stated, "I don't need 'em any more." There was nothing in the mental content that coincided with the previously described hallucinations, delusions, or agitation. It was noted that the patient was trying to write letters home and that he was beginning to think about his prospects for being discharged. When seen Feb. 1, 1955, for the third revaluation, the patient continued to be free of any need for restraints. The mental content was free of material suggesting hallucinations or delusions, and a steady improvement in comprehension was noted. There was a continuation of involuntary crying, as had been noted in the two previous examinations, but the patient had now learned to proceed with his conversation in spite of it. A greater preoccupation with home and family was noted. The residual slight impairment of orientation, memory, and intellectual function was attributed to a premorbid chronic brain syndrome presumably of arteriosclerotic origin.

This 66-year-old veteran was admitted to the hospital with the diagnosis of an unclassified psychotic reaction. Since the patient had been receiving reserpine and Rauwolfia compounds, the possibility of a toxic drug psychosis was considered. Following the withdrawal of medicaments a marked clearing of the mental status was noticed. At the present time the only mental residuals are those that can be attributed to a chronic brain syndrome of presumably arteriosclerotic origin. As observed in the first case, this patient had a toxic drug reaction that accentuated a premorbid personality pattern. Since patients having a chronic brain syndrome usually show mental clouding and confusion, it is interesting to observe that in this patient the drug toxicity caused such an accentuation of the premorbid personality pattern that a classic psychosis, manifested by terrifying hallucinations and delusions, ensued.

COMMENT

With any new drug, the question of mechanism or locus of action is most important from the standpoint of its rational therapeutic application. The slowness of action of the drugs Rauwolfia and reserpine suggests that they work through some hormonal or other intermediate mechanism. One of the hormonal routes currently suggested is the adrenal cortex. Gaunt[2] and Winsor[3] feel that the adrenal stimulation is of a nonspecific nature, inasmuch as human subjects receiving reserpine respond normally to corticotropin. Unanswered is the question whether the tranquilizing action of the drug will depress the endogenous mechanism discharging corticotropin in psychogenic stress.[2]

The available evidence suggests that Rauwolfia compounds and reserpine exhibit neither peripheral adrenolytic nor peripheral parasympathomimetic activity. Bein[4] has ruled out the blockade of transmission in the autonomic ganglia because such activity, as might be anticipated, would be reflected in depression of both sympathetic and parasympathetic function. Since the electroencephalogram of an animal markedly quieted with reserpine showed a normal pattern in contrast to the sleep pattern shown with barbiturates,[5] it has been assumed that the alteration of autonomic balance might be within an area of the central nervous system. The hypothalamus, where the autonomic nervous functions are integrated, may be responsible for the observed effects of reserpine.

According to Hess,[6] sleep is a parasympathetic function that is brought about by a suspension of the activity of the sympathetic center in the hypothalamus. He, moreover, has produced sleep by electrical stimulation of the anterior hypothalamic region in the vicinity of the parasympathetic center. Since, besides sedation, Rauwolfia compounds and reserpine cause symptoms suggesting parasympathetic dominance, such as bradycardia, miosis, and increased secretory and motor activity of the gastrointestinal tract, it appears logical to suggest that this might be accomplished by a partial suspension of the activity of the sympathetic center in the hypothalamus.

Other than blood pressure reduction, according to Moyer,[7] these are the effects, in descending order of frequency, that most often follow reserpine administration: bradycardia in 71% of cases, nasal congestion in 65%, increased appetite in 60%, sedation in 47%, fatigue and weakness in 44%, sense of well-being in 35%, dizziness in 21%, increased bowel movements in 3%, and dreams in 2%. Wilkins [8] has observed that some men complain about a decrease in libido, while two men, one with mild alcoholism, developed definite and painful gynecomastia. Although there is no evidence of tolerance to the dosage, the effects of the medicament continue for two to six weeks following the cessation of therapy. Because they are remarkably well tolerated over a prolonged period of time and generally free from toxic and very severe side-effects, Rauwolfia compounds or reserpine are in others as well as our opinion not only the first agents to try when initiating medical treatment for hypertension but also the last ones to omit from such a regimen.

If one reads the current lay press, he will easily gather the impression that "Rauwolfia is good psychotherapy in pill form." Kline,[9] in fact, feels that Rauwolfia compounds can reduce anxiety and obsessive drives and will overcome excessive inhibitions and reticence. As the usage of the drug becomes more widespread, the psychotherapeutic potentialities of Rauwolfia appear to have some definite limitations. An interesting reaction, which occurs infrequently, is the refusal of certain persons to submit to the tranquilizing effect.[10] Instead of relaxing and accepting a calm tranquil state, they become most uncomfortable, perhaps because the sensation is foreign to their usual nature. The occurrence of mental depression as previously described by Wilkins,[8] Dustan,[11] and Freis,[1] and now a psychotic reaction as here presented, suggests that some caution should be used in the use of Rauwolfia compounds. This includes the normotensive as well as the hypertensive patient.

Almost as perplexing as the proper patient selection is the dilemma of whether to continue the Rauwolfia or reserpine medication once the patient develops a mental reaction. In some it may be that a period of mental turbulence is necessary before the emotional effectiveness of the drug can be achieved. Barsa and Kline [12] in their study of 150 chronically disturbed psychotic patients given large doses of reserpine distinguished three stages in the course of treatment: the sedative period, the turbulent period, and the integrative period. If the patient could successfully pass through the turbulent phase, with its increased delusions and hallucinations, the integrative phase would be reached. As yet, however, it is doubtful in a nonpsychotic patient whether one should continue the medication in the turbulent phase in order to attain the integrative phase. One must always consider the possibility that a lasting mental derangement might be precipitated by perpetuating the turbulent state in a person with limited ego strength.[13]

To differentiate a toxic from a functional psychosis is often a most difficult task. Bleuler,[14] however, feels that true autism in a toxic psychosis is rare, since there is no essential dissolution of concepts and no splitting of the personality. There is frequently in the toxic psychosis a "mental clouding" involving some degree of disorientation, which ranges from fluctuations in attention, comprehension, and memory to confusion and delirium. A high incidence of perceptual distortions involving visual and auditory illusions and hallucinations is noted.[15] In the personality sphere, the form and content of the deviation are independent of the causal agent [16]; the changes represent an accentuation of the premorbid personality pattern.[17]

In use of Rauwolfia alkaloids, caution and close observation are particularly suggested for individuals who appear to be maintaining a marginal emotional adjustment by virtue of previous brain damage or a functional psychiatric disorder. In contrast to the normal individual who can recognize and adjust to the exogenous nature of the disturbance, the "borderline" individual has difficulty sensing whether his reaction is of toxic or endopsychic origin. Utilizing a conditioned response, he draws upon the habitual personality defenses to cope with the added stress. Lacking, as he usually does, sufficient personality resources to cope with the added stress, the result is further ego weakening and disintegration, with a subsequent eruption into consciousness of psychopathology. There appears to be no relationship between the onset of emotional symptoms and the initiation of therapy. Although a lessening of the dosage might be helpful, associated personality disturbances are not necessarily related to the degree of drug intoxication; they are "released" by the intoxication and superimposed upon it. Finally, restraint is advised when the

compounds are administered to otherwise normal persons who function under unusual stress with only a modicum of personality control.

SUMMARY

Although Rauwolfia compounds and reserpine (Serpasil) generally exercise a tranquilizing as well as hypotensive effect, they can be responsible for severe mental disturbances. Within a period of three months we have seen four patients treated for hypertension, and with disturbances secondary to Rauwolfia and reserpine therapy, three of whom were suffering from mental depression and one of whom had a psychotic reaction. These reactions tend to occur in the "borderline" individual who has difficulty maintaining a marginal emotional adjustment by virtue of previous brain damage or a functional psychiatric disorder. Despite the disturbances described, we feel that Rauwolfia compounds and reserpine should be the keystone of treatment of hypertension. However, caution and close observation should accompany the drug therapy in all patients. In addition to the hypertension, one should consider an individual's inherent personality pattern, his current ego strength, and the environmental pressures to which he is subject.

TREATMENT OF DELIRIUM TREMENS WITH RESERPINE (SERPASIL)

A PRELIMINARY REPORT

Milton Avol, M.D.
and
Philip J. Vogel, M.D., Los Angeles

The problem of the treatment of the acutely alcoholic patient has been the topic of countless papers in the past few years.[1] However, despite the many writings on the subject of treatment of postalcoholic withdrawal symptoms, management of these symptoms still revolves around intravenously given fluids for hydration, high doses of vitamins, and large doses of paraldehyde to control the extreme excitation and acute hallucinatory episodes these patients exhibit. Anyone familiar with this mode of therapy can attest to the fact that it is far from being satisfactory. For adequate control of these extremely agitated patients, they must be given massive doses of paraldehyde to the point where they are literally semicomatose. This then increases tremendously the amount of nursing care required per patient, for then intravenous administration of fluids, frequent turning, bathing, catheterization, and changing of linens are required. In addition, these patients are oftener than not in a very debilitated state and the necessity of keeping them continually semicomatose greatly increases the incidence of pneumonia and urinary infections. Furthermore, the odor of paraldehyde that pervades the wards and corridors is very distressing to the remainder of the patients and ward personnel. These alcoholic patients very quickly develop a tolerance to paraldehyde, so that even massive doses are ineffective or only partially effective in controlling their agitation. Finally, with this treatment regimen, it sometimes takes as long as five or six days before the patient is free of hallucinations, agitation, and tremors.

While studying use of reserpine (Serpasil) as a tranquilizer in therapy of various neurological disorders, especially acute head injuries, we were impressed by its effectiveness in controlling acute hallucinatory episodes in several patients. It therefore occurred to us that it might be helpful in the management of the patient with delirium tremens. Our results with reserpine therapy have been so very gratifying that it was thought worthwhile to summarize them in this preliminary report in order to obtain a more widespread trial of the drug in the treatment of delirium tremens.

CLINICAL MATERIAL

A total of 24 patients with delirium tremens has been treated since the study was begun on Oct. 5, 1954. These patients were carefully selected so that only those with severe delirium tremens manifesting extreme agitation and excitement with marked hallucinations were placed under treatment. There were 18 males and 6 females in the series, the average age of the former being 47.2 years and of the latter 45.6 years. The ages ranged from 31 to 65 in the males and 37 to 64 in the females. The majority were patients with chronic alcoholism of the type seen in a charity hospital, who were suffering from malnutrition and dehydration and who had had several previous admissions for alcoholism or delirium tremens. Because of their marked excitement and intense fear of such things as "snakes," "little men," "bugs," and "two-headed elephants," they all had to be kept in firm restraints. In addition, most of these patients were extremely noisy, shouting at imaginary persons and talking abusively to the ward personnel.

It was difficult to obtain suitable controls for a series such as this. However, from observations on other patients with marked delirium tremens who were given the usual treatment with paraldehyde and from some of the observations made on the present series of patients, a good basis of comparison could be obtained as to the efficacy of the treatment. During the course of this

study blood pressure readings were taken before the reserpine was administered and during treatment. Observations were also made as to the time of disappearance of hallucinations and confusion, as well as the relief of the tremors or "shakes" with which many of these patients were afflicted.

TREATMENT AND DOSAGE

Several papers have appeared in the recent literature detailing the use of reserpine in hypertension.[2] These have adequately covered the question of dosage for this particular disease. However, we were dealing with an entirely different problem in this instance—treatment of acute illness, the termination of which we wanted to effect in a matter of hours. Obviously, this required an entirely different dosage schedule and method of administration. The use of reserpine for other than the treatment of hypertension is so new, however, that only two papers had appeared on the subject before our study.[3] While these studies were of some help in giving us an idea of the relative limits of safety of the drug, they were of no avail in helping us to determine the optimum dosage and dosage schedules to be used for the more acute illness that we were treating. It was like groping about in the dark to ascertain the maximum amount of parenterally administered reserpine that could be utilized with safety in order to alleviate as rapidly as possible the marked hallucinations with which these patients were afflicted. Moreover, reserpine is known to cause an increase in gastric secretion and, because of the high incidence of alcoholic gastritis in these patients, we began the study with some fear and trepidation. It should, therefore, be kept in mind that the results we are reporting are not necessarily the optimum that can be expected from the use of this drug. Work is continuing to determine further the best dosage schedules. In our series reserpine was administered parenterally in all cases because (1) it was essential to have the drug act as rapidly as possible, and (2) many of the patients could not be induced to take a medicament orally.

From previous studies in the treatment of hypertension, we know that it requires at least one to two weeks for any effects to be seen from oral medication. This obviously was not suitable for our purpose. Of the total patients in the series, 13 were treated by the intravenous route, 8 by the intramuscular, and 3 by a combination of the intravenous and intramuscular routes. We have given as much as 5 mg. intravenously, injected over a period of one minute, to these alcoholic addicts without ever noticing any ill-effects on the patient. However, because we have had several instances of annoying side-effects (hypotension, nausea, and vomiting) after using 5 mg. doses in another series of patients in whom the drug was used for reasons other than delirium tremens, we have preferred to give the drug in two equal doses of 2.5 mg. each about three hours apart. This has usually been sufficient to cause the patient to be free of all hallucinations in 24 hours. In many instances this relief was obtained within 18 hours. The shortest recovery period that we have experienced was nine hours in three of our patients. However, in several cases, while the patient was much more calm and manageable in 24 hours, it required a repeated dose of 2.5 mg. to 5 mg. intramuscularly in order to free the patient entirely of his hallucinations.

It appears from our short series that intravenous administration of the drug produces a more rapid effect than the intramuscular route. However, because excellent results could be seen with either route in 24 hours, it seems preferable to use intramuscular administration as much as possible because of the greater convenience and less potential hazard involved. Of course, if it were desired to get the patient under control as rapidly as possible, the intravenous route is the preferable one. Again it should be emphasized that we have seen no untoward effects with either method of administration in this series of patients.

The routine we followed was to place all of the patients on the previously used regimen for the treatment of acute alcoholism, including intravenous administration of fluids and high doses of vitamins, except for the omission of the high doses of paraldehyde. The patients were then given a dose of reserpine intravenously or intramuscularly. The medicament was first used intravenously in 5 mg. doses. Later in the series several patients were given 2.5 mg. intravenously and 2.5 mg. intramuscularly at the same time. This was later changed to 2.5 mg. followed in three to four hours by another dose of 2.5 mg. intravenously or intramuscularly if the patients were still agitated. Usually the patients would require the second dose of 2.5 mg. Ordinarily these patients would begin to quiet down in six to eight hours. However, in one instance the patient remained so agitated that a third injection of 2.5 mg. was given four hours after the second dose. Because of the delay in the onset of action of reserpine, many patients were also given a dose of paraldehyde (10 cc.) initially in order to help keep them controlled for the first few hours.

RESULTS

All but three of the patients studied were relieved of their symptoms in 24 hours or less. In these three patients the state of agitation was markedly improved, though they were still slightly confused and had mild hallucinations that apparently did not give them much concern. They were each given another dose of 5 mg. of reserpine intramuscularly and within 12 hours were entirely free of symptoms. It is entirely possible that had these three patients been given a third dose of 2.5 mg. of reserpine during the first 24 hours their symptoms would have been alleviated much sooner.

In the entire series, the 16 patients who were given the dose intravenously or by combined intravenous and intramuscular administration were free of the symptoms in an average of 18 hours while the 8 who had received the drug intramuscularly were entirely free of symptoms in an average of 28 hours. The tranquilizing effects of the drug usually became apparent in six to eight hours. Five were entirely free of symptoms in 12 hours, and nine more were entirely relieved in 18 hours. The longest period required for a patient to be entirely symptom-free was 48 hours, which occurred in two instances. However, as has already been stated, these two patients were markedly relieved of their excitement and tremors within 24 hours, the only residuals being a continuation of their visual hallucinations in a much milder form for another 24 hours. One man, for instance, continued to see "baldheaded men with sheepskin coats" in the room and another noted "elephants with lots of heads," but these were not as numerous and not as frightening as those seen the day previously.

All patients were fully awake or only slightly drowsy the following day. Of the few who were drowsy, those who tended to fall asleep were easily awakened and responded to questioning readily and coherently. It should be kept in mind that these patients had received a relatively large dosage of reserpine compared to the dosage usually employed in chronic diseases like hypertension, which may account for the increased drowsiness. Several of the patients of this series had to be given an initial dose of paraldehyde (10 cc.) in order to control their marked agitation until the reserpine could take effect. While this medicament may have contributed to the drowsiness of the patients, it is extremely doubtful that it played any significant role in controlling their hallucinations. Anyone familiar with the care of alcoholic addicts is cognizant of the great tolerance these patients have to paraldehyde. Many of these patients had had several previous admissions to the hospital for alcoholism and had received paraldehyde on many other occasions. In fact, some of the men spontaneously requested extra doses of paraldehyde since the ordinary doses were without effect, so we can thus discount any effects due to the small dose of paraldehyde as being negligible. In our series two cases aptly illustrate this point as well as the comparative effectiveness of reserpine and of paraldehyde.

REPORT OF CASES

Case 1.—The patient, a 40-year-old Caucasian male, had had many previous admissions to the Los Angeles County General Hospital for alcoholism and delirium tremens. He was first seen by us on Nov. 16, 1954, at which time he was having very marked delirium tremens. Despite restraints on all four extremities and a sheet about his chest, he was half sitting in bed shouting at the "little men and Nazis" who were trying to put him in a concentration camp. He was given 5 mg. of reserpine intravenously in one injection because of his extreme agitation and within 18 hours was entirely free of his hallucinations, well oriented though somewhat drowsy, and ambulating about the ward. The patient was discharged the following day perfectly alert and oriented.

He was readmitted late at night on Jan. 5, 1955, with delirium tremens, but we were not informed of this until the following afternoon. In the meantime he had received a total of 60 cc. of paraldehyde in three doses within a 10-hour period; when we first saw him 4 hours after the last dose, he was almost unresponsive. However, when aroused with great effort, he was still seeing fierce tigers with "lots of heads." He was given 5 mg. of reserpine intramuscularly in one dose. We did not wish to give the drug intravenously because of the fear of an adverse reaction due to the tremendous quantity of paraldehyde that the patient had received. Twenty-four hours later he was awake and talking and taking feedings orally. He was still seeing a few animals with many heads, but they were much less numerous and did not cause as much anxiety and agitation as previously. After another dose of 5 mg. of reserpine intramuscularly, the patient became free of hallucinations the following day.

Thus, this patient was made symptom-free within 18 hours by the use of reserpine whereas he was not relieved of his symptoms after the use of massive doses of paraldehyde.

Case 2.—A 59-year-old Caucasian male was admitted on Nov. 11, 1954, to the Los Angeles County General Hospital. He had been in an auto accident and was admitted with multiple fractures of his right extremities. He had chronic alcoholism, with several previous admissions for acute alcoholism and delirium tremens. Shortly after the present admission, he began to note "little men" on the ceiling and requested paraldehyde, as he knew from previous experience that he was going into delirium tremens. He was given reserpine, 2.5 mg. intravenously and 2.5 mg. intramuscularly at the same time. Within nine hours he was entirely free of his hallucinations. The patient was given no further sedation or reserpine and continued to be free of hallucinations for 48 hours. However, during the night of Nov. 13, 1954, he again became very restless and hallucinatory and was given paraldehyde, since there was no reserpine for parenteral administration immediately available on the ward. He was continued on the paraldehyde therapy, but it was not until 36 hours later that he was free of his hallucinations.

This case provides a very good example of the comparative effectiveness of reserpine and paraldehyde—the former requiring 9 hours to the latter's 36 hours for the relief of symptoms. Interestingly enough, it also provides us with an idea as to the duration of action of the drug (about 48 hours), which agrees very closely to the experimental findings in dogs (36 to 48 hours) as reported by Plummer and co-workers.[4]

In treating an illness such as delirium tremens it is understandably very difficult to find an adequate and comparable control series. However, in our experience and that of others of the staff of the Los Angeles County General Hospital, it may take as long as four to six days for a patient with severe delirium tremens, such as we included in our series, to become symptom-free. We have seen several examples of these patients who have been treated for three to four days on the usual regime (with paraldehyde used for sedation) with only partial relief of symptoms. Albert and associates,[5] reporting a series of cases of alcoholism treated with chlorpromazine, stated that it required as long as four days of therapy to overcome the excitatory state of delirium tremens. Comparison of these experiences with our results makes us feel that the use of reserpine in delirium tremens holds great promise.

SIDE-EFFECTS

The question naturally arises as to the comparative safety of this drug and the incidence of annoying or dangerous side-effects. Several previous papers on the long-term use of the drug in hypertension have reported such effects as bradycardia, nasal congestion, drowsiness, nausea, and dizziness.[6] It also has been found that reserpine may increase gastric secretion. The latter finding, especially in a patient with acute alcoholic gastritis, would be very disconcerting. However, except for some drowsiness and in one instance bradycardia (pulse of 60 per minute), we have had no difficulty with any of the reported side-effects in our study. Incidentally, the patient with the slow pulse apparently had no ill-effects. Apparently, the usual treatment that these patients receive for gastritis on admission is sufficient to overcome or allay any of the effects of increased gastric secretion due to the drug.

[6] Dustan, H. P.; Taylor, R. D.; Corcoran, A. C., and Page, I. H.: *Clinical Experience with Reserpine (Serpasil): A Controlled Study*, Ann. New York Acad. Sc. **59**: 136 (April 30) 1954. Wilkins.[2c]

Of course, it must be realized that the original use for reserpine, viz. as a hypotensive agent, would be considered a side-effect in the present indication. However, despite the comparatively large doses that these patients received, the average fall in blood pressure was 15 mm. Hg systolic and 10 mm. Hg diastolic. As a matter of fact, two of the patients actually had rises in systolic blood pressure of 18 and 10 mm. Hg. It should be pointed out, however, that all of these patients in the group, with but one exception, were normotensive. Moreover, these patients were all confined to bed for the first 24 hours. It has been our experience with other series of patients treated with reserpine for various neuropsychiatric disorders that normotensive individuals do not ordinarily get the same hypotensive effects from the drug as do hypertensive patients. Furthermore, the effect is usually that of an orthostatic hypotension, which of course would not be apparent in these necessarily bedfast patients. However, when these patients became ambulatory 18 to 24 hours later, no ill-effects of any kind were noted.

We feel that the drug should be used with caution in patients with heart disease or previous cerebral vascular accidents and in those with hypertension. However, these are by no means to be considered as contraindications. We have had occasion to use the drug in a patient with congestive heart failure who was having severe delirium tremens. This patient was hallucinating actively, seeing numerous "black cats" and "lots of men" coming after him. He was given 5 mg. of reserpine intramuscularly and in 18 hours was free of his hallucinations. Paradoxically his blood pressure before the reserpine was 104/60 and 24 hours later was 122/68. His pulse rate fell from 90 to 76 during this period.

However, in one case of another series in which this drug was used we have seen a sudden marked drop in blood pressure after the intravenous injection of 5 mg. of reserpine. This patient was hypertensive, his blood pressure being 180/120. Within three hours after the injection he became comatose and his blood pressure was barely obtainable. Fortunately, the pressure was brought back to normal levels in a few minutes with the use of levarterenol (Levophed) bitartrate intravenously, and the patient reacted and was talking again in minutes. This case should not be taken to imply that the drug is contraindicated in hypertensive individuals. Nor does it mean that a 5 mg. dose intravenously should not be used if the need arises. As a matter of fact we know of several cases in which doses as high as 20 mg. intravenously were used (in toxemias of pregnancy) without ill-effects.[7] This case, however, does serve to point out what others as well as we have experienced, namely, that a small percentage of individuals, especially those with hypertension may react adversely to a medicament used intravenously in high doses. It therefore should be used with caution, especially in patients with a previous history of cardiovascular disease.

From the little experience that we have had, there is apparently no correlation between the hypotensive and tranquilizing effects of the drug. In another series of cases we have seen patients who have had a marked fall in blood pressure without any apparent effect on their mental or emotional status, and conversely we have seen gratifying effects on emotional disorders without any deleterious effect on the blood pressure or pulse. Moreover, the effects on the blood pressure are usually apparent within two hours after a dose intravenously, whereas the emotional effects are not apparent for at least six hours. We have had no difficulty with symptoms of nasal congestion or epistaxis as the result of the use of this drug. We have also had no difficulty with nausea or vomiting in these patients, apparently because of the fact that they were getting treatment (antacids and anticholinergic drugs) for their alcoholic gastritis at the time that they were given the reserpine.

COMMENT

From our experience with reserpine, we have gained the impression that its pharmacological action is more like that of digitalis. It requires a certain blood level before it can be effective. Its action is not immediate like that of the barbiturates given intravenously but is noted only after several hours. Moreover the duration of action is prolonged over a period of 36 to 48 hours. Furthermore, as with digitalis, the dosage has to be individualized, as different patients will get varying reactions from the same dose.

From our experience thus far, it appears that the safest and most effective method of administration is in a dose of 2.5 mg. intramuscularly or intravenously to be followed in three hours with another dose of 2.5 mg. if necessary. This dose may again be repeated in four hours if the patient is still markedly agitated. However, if the patient becomes drowsy, it is best not to give any further medication until the following day. At that time, if the patient is still having hallucinations, another dose of 2.5 mg. would probably be sufficient to control the symptoms. The medicament does not have to be given by intravenous drip, but, by giving it in divided doses as suggested above, there is less danger of an adverse reaction ensuing. Again, it should be emphasized that the dosage must be individualized. Further, until more is known about the drug it is best not to push it too vigorously unless one is faced with a very acute situation. Under ordinary circumstances, it is best to give the medicament in the suggested dosage and to wait a few hours longer for the desired results than to have to be faced with treating an adverse reaction to the drug.

---

[7] Assali, N.: Personal communication to the authors.

It would seem to be worthwhile to continue the patient on a daily maintenance dose of 1 to 2 mg. of reserpine orally over a prolonged period of time in order to alleviate some of the anxiety that causes these patients to resume drinking soon after discharge from the hospital. We have been unable to put this program into operation at this hospital, however, because of the lack of adequate personnel and facilities. A prolonged clinical follow-up on this use of reserpine in a facility geared to this type of work might prove to be very valuable.

SUMMARY

Twenty-three patients were treated with reserpine (Serpasil) in an attempt to control the symptoms of delirium tremens. The drug was given parenterally in relatively large doses ranging from 2.5 mg. to 5 mg. in one injection. The patients were free of their symptoms of acute hallucinations in an average of 18 hours. Most of the patients were free of their symptoms within 24 hours. However, the shortest period of time noted was 9 hours (in two patients) and the longest was 48 hours (in two patients).

Despite the relatively large doses utilized, there were no ill-effects noted in this series. Hypertensive cardiovascular disease per se is not a contraindication to the use of the drug, although the drug should be used with great caution in these instances. Because of the great variation in reaction to this drug, the dose should be individualized. However, we have found that an initial dose of 2.5 mg. to be followed in three hours by another dose of 2.5 mg., if necessary, is fairly safe for all patients. The use of this drug has greatly shortened the time necessary to free these patients of their postalcoholic withdrawal symptoms. Moreover, they are a much easier group to care for from the point of view of nursing. We believe that the use of reserpine has shown very gratifying results in the treatment of delirium tremens and warrants further trial.

DANGERS IN COMBINING RESERPINE (SERPASIL) WITH ELECTROCONVULSIVE THERAPY

Merritt W. Foster Jr., M.D.
and
R. Finley Gayle Jr., M.D., Richmond, Va.

Within the past two years reserpine has enjoyed an increasing and ever-expanding popularity in therapeutic usage in this country, particularly because of its rather specific hypotensive effect, and in recent months there has been a growing enthusiasm in the use of reserpine for the treatment of many psychiatric illnesses. Noce and others [1] were enthusiastic about the value of this drug in treatment of agitated and overactive states. They reported dramatic responses in patients who had been unmanageable and who had not responded previously to certain of the so-called physical therapys, particularly electroshock treatment. Originally more conservative in reported results, Kline [2] has recently also described most encouraging effects with the use of reserpine.

Earlier studies [3] on the pharmacology of this drug emphasize that it has very low toxicity. Monkeys have tolerated orally given doses up to 3 mg. per kilogram of body weight daily for six months and single intravenously given doses up to 4 mg. per kilogram without significant ill-effects. It has also been reported that a 20-month-old child accidentally ingested about 200 mg. of crystalline reserpine without critical ill-effect.

RESULTS

In our series of cases reserpine (Serpasil), both parenterally and by mouth, has proved a very helpful adjunct in the treatment of a number of psychiatric illnesses. It is the purpose of this report, however, to describe certain dangerous side-effects we have observed when this drug has been combined with electroconvulsive therapy, even though we have given relatively lower dosage than that reported by others in similar cases. We have given no more than 5 mg. a day parenterally to any one patient, with orally given doses varying between 0.25 mg. four times a day and 1 mg. twice a day. Until quite recently the side-effects in our cases corresponded with those already reported, namely, nasal stuffiness, lassitude, weakness, nightmares, vertigo, and diarrhea. Only on rare occasions were they considered sufficient reason for discontinuing medication. In the three months before we prepared this report, however, we witnessed several severe reactions in the use of reserpine combined with electroconvulsive treatment. One patient died; in three other patients the vital signs were imperceptible for several minutes, the patients remain-

ing extremely confused, lethargic, and weak for the following six to eight hours. Two other patients suffered falls in blood pressure to shock levels, which persisted for several hours after the electroconvulsive treatment.

These reactions occurred in a series of 63 patients given both reserpine and electroconvulsive treatments during the past year. A subsequent review of these cases has not revealed any predictable contraindication for this combination either in objective records of the patients' physical states or in their reported subjective sensations. There was also no correlation in terms of the drug dosage. Other patients in the total series tolerated a combination of reserpine, 2 mg. by mouth and 5 mg. intramuscularly daily, plus electroconvulsive treatments three times a week for periods as long as three months without showing any side-effect but mild drowsiness.

Since reserpine has proved effective and increasingly popular in the management of disturbed patients, the possibility of similar occurrences elsewhere is further enhanced. In addition, it has been recently reported [2b] that a period of transient excitement with exacerbation of symptoms is a characteristic stage of treatment with reserpine. This might lead some doctors to start electroconvulsive treatment immediately without stopping reserpine therapy, and we have the very definite clinical impression that such a combination is dangerous.

REPORT OF CASES

Case 1.—A 49-year-old white male was admitted to the hospital because of increased motor activity, pressure of speech, flight of ideas, and other symptoms of manic excitement. It was necessary to keep this patient in seclusion and, in controlling his motor excitement, to use amobarbital (Amytal) sodium intravenously on several occasions. The last dose, 250 mg., was administered 13 hours prior to his terminal episode and had little effect on his excited state. For three days prior to admission this patient was given a total of 1 mg. of reserpine orally each day. Shortly after admission he was given 2.5 mg. of reserpine intramuscularly with no amelioration of symptoms. On the patient's third hospital day, at 11:30 a. m., he was given another injection of 2.5 mg. of reserpine intramuscularly. Four and a half hours later he received an electroconvulsive treatment. The patient failed to breathe after this treatment and had no pulse. He was immediately given the usual respiratory and cardiac stimulants and artificial respiration with oxygen but failed to respond. Postmortem examination revealed cerebral edema, pulmonary edema, very mild cardiac hypertrophy (although there was no evidence of hypertension premorbidly), and mild hyperplasia of the adrenal cortex. It was the opinion of the pathologist that postmortem findings, both gross and microscopic, did not show anatomic cause for this patient's death.

Case 2.—A 45-year-old white female entered the hospital in a state of overactivity and overtalkativeness of about 10 days' duration somewhat similar to that in case 1. Within 24 hours of admission to the hospital, the patient was started on a regimen of 2.5 mg. of reserpine intramuscularly twice a day. After five days of this treatment, the patient's symptoms abated slightly, but it was felt that electroconvulsive treatments should be added. Mindful of the possible effect of reserpine in the previous case, the dosage was reduced in this patient on the day prior to treatment with the last dose given at bedtime. The next morning, 12 hours after this injection, the patient was given an electroconvulsive treatment. The patient's vital signs could not be obtained for several minutes following this. Cardiac and respiratory stimulants and artificial respiration with oxygen were immediately administered and the patient gradually responded, although the pulse and spontaneous respiration were not evident for approximately 15 minutes after the treatment. The patient remained lethargic for the following 12 hours and in addition developed bilateral pitting edema of both lower extremities. Reserpine therapy was discontinued, and the patient was studied exhaustively, both clinically from a physical and neurological standpoint and with comprehensive laboratory studies. These included the usual complete blood cell count, urinalysis, and studies of blood sugar, urea nitrogen, sodium, and potassium levels. Electrocardiographic and chest x-ray examination were also repeated. None of these examinations revealed any abnormalities. After a lapse of four days after the termination of the reserpine therapy, electroconvulsive treatments were resumed. The patient responded promptly after each treatment.

Case 3.—A 52-year-old white female was admitted to the hospital with agitation, depression, and other symptoms characteristic of an involutional psychotic reaction. After her admission studies and a period of several days' observation, the patient was given a course of electroconvulsive therapy. After the ninth treatment, with only slight improvement of symptoms, she was given 2.5 mg. of reserpine intramuscularly twice a day. After only two injections of reserpine, with the last having been given the preceding evening, the patient was given her 10th electroconvulsive treatment. This was followed by a prolonged period of apnea, and her pulse was discernible only intermittently. With institution of the usual heroic stimulants her respiration spontaneously resumed and after about 10 minutes her pulse became full and regular, but she continued to be lethargic with generalized motor weakness for several hours. Intramuscular administration of reserpine was then discontinued, and four days later electroconvulsive treatment was reinstituted. She received eight subsequent treatments, which she tolerated well.

Case 4.—A 29-year-old white female was admitted to the hospital with the diagnosis of schizophrenic reaction, hebephrenic type. On admission the patient was slowed-up, withdrawn, and negativistic, with alternating periods of aggressive and assaultive behavior. One milligram of reserpine was given orally each day. Three days after admission electroconvulsive treatments were started and she was given one a day for three days. After the third treatment there was the same prolonged period of apnea and lack of discernible pulse described in the previous cases. She eventually responded to resuscitative measures but continued to be quite confused and lethargic the remainder of the day.

Case 5.—A patient had been receiving electroconvulsive treatments for some months in addition to being given 1 mg. of reserpine orally each day. After an isolated electroconvulsive treatment, the patient showed a precipitous fall in blood pressure, which persisted for some two hours after treatment at levels of 80/40 mm. Hg. This was accompanied by subjective and objective drowsiness and confusion. The orally given dose of reserpine was reduced by one-half, and two weeks later the patient again received an electroconvulsive treatment with no untoward side-effects.

Case 6.—A 55-year-old female was admitted to the hospital with ideas of reference, auditory hallucinations, religious preoccupation, and periods of agitated depression. The result of physical examination was not remarkable except for a blood pressure of 150/90 mm. Hg and a transient sinus tachycardia with pulse rate of 130. She was given a course of 10 electroconvulsive treatments, and after the seventh treatment she was also given 2.5 mg. of reserpine intramuscularly twice a day; this therapy was continued for 11 days beyond the termination of electroconvulsive treatments. Suddenly on the 12th day the patient became stuporous and pale, sweating profusely. The blood pressure was recorded at 80/40 mm. Hg with a pulse rate of 60. Reserpine therapy was discontinued and the blood pressure gradually returned to previous levels with the symptoms resolving over a period of several hours. Immediate investigation, both during and after this attack, was conducted with complete neurological study and thorough examination by the medical department. This survey failed to find an anatomic or pathological cause for the reaction. This does not necessarily mean that none existed, but it is known that this patient had been receiving 5 mg. of reserpine intramuscularly for the preceding 24 days and for the first 5 days in combination with electroconvulsive treatment.

COMMENT

Attempts to explain the reaction seen in these patients have proved unrewarding. This is further compounded by the fact that studies to determine accurately either the site or mode of action in electroconvulsive treatments have not been convincing. Other investigators have held that, because of the latent period following intravenous injection of reserpine, subsequent effects are due to some unknown product of the further metabolism of the drug. There seems to be agreement that this breakdown product suppresses the sympathetic centers in the hypothalamic area of the brain stem.[4] Experimentally, acute lethal doses in animals caused respiratory failure on a central basis. Reserpine,[3a] however, did not block the pressor response following increased intracranial pressure, which according to Yesinick and Gellhorn, is due to asphyxial stimulation of the vasomotor center. Reserpine, also, has been shown to lower the convulsive threshold in animals, yet in our cases minimal convulsive levels of current were used. In the fatality reported one might question the part played by barbiturates, and yet the final intravenous dose of 250 mg. preceded the intramuscular use of reserpine by 8½ hours and the electroconvulsive treatment by 13 hours. Postmortem examination did not show any reason why the barbiturate would not have been destroyed and excreted in that time. Complete physical and laboratory studies, both before and after the critical treatment, did not reveal a predictable reason for the untoward reactions.

SUMMARY

Severe reactions, including one fatality, have been observed in 6 of a total of 63 patients receiving a combination of reserpine (Serpasil) and electroconvulsive treatment. There was no correlation between either the amount or the route of administration of reserpine and the severity of the reaction. Minimal convulsive dosage was employed with the electroconvulsive apparatus. Complete clinical and laboratory studies of the patients both before and after the critical treatments did not show an adequate or predictable cause for the untoward effects in these particular patients.

ADDENDUM

Since the date of writing of this report, we have found evidence indicating that a minimum of seven days should elapse after reserpine therapy before the initiation of electroconvulsive treatment.

PROGRESS REPORT ON THE POLIOMYELITIS VACCINE PROGRAM

Otis L. Anderson, M.D., Washington, D. C.

Within a relatively short space of time there has been significant progress toward immunizing the most susceptible segment of the nation's population against poliomyelitis. At the inception of the program, with only six manufacturers licensed to produce the vaccine, it was obvious that demand would far exceed the supply. Recognizing this problem, the Secretary of the Department of Health, Education, and Welfare appointed the National Advisory Committee on Poliomyelitis Vaccine to make recommendations regarding the most satisfactory method of equitably distributing the vaccine available. This committee is broadly representative of the medical profession, pharmaceutical and drug industries, parents and teachers groups, and state and local health agencies. Dr. Chester S. Keefer, until recently Special Assistant to the Secretary for Health and Medical Affairs, is chairman of the committee. The secretariat is made up of staff of the Public Health Service. Based on recommendations of the National Advisory Committee, the voluntary system of allocating vaccine among the States was adopted by the Department of Health, Education, and Welfare.

ALLOCATION SYSTEM

Under the voluntary allocation system developed, it is the responsibility of the federal government to arrange for the equitable apportioning of poliomyelitis vaccine among the states—in accordance with each state's population in the currently recommended priority group. In formulating plans for the interstate distribution of vaccine, the Public Health Service consulted extensively with the vaccine manufacturers, representatives of the pharmaceutical and drug industries, and the Association of State and Territorial Health Officers. With the concurrence of these groups, each state is allocated its proportionate share of the vaccine supply periodically cleared and released by the National Institutes of Health.

The equitable intrastate allocation of vaccine is the responsibility of each state. Each governor has appointed an individual—in all cases the state health authority—to be responsible for this program in his state. Each state has also appointed an advisory committee with medical, pharmaceutical, drug, and—in some cases—other appropriate representatives to assist in the program. The state is responsible for determining the percentage of its share of all vaccine released that will be purchased by public agencies, and the percentage to be sold through commercial channels to drugstores and physicians. This decision on the part of each state is passed on to the vaccine manufacturers by the Public Health Service. The manufacturers have all agreed to adhere to state wishes in the sale of vaccine.

During the early months of the program, the National Advisory Committee recommended that its administra-

---

Assistant Surgeon General; Chief, Bureau of State Services, Public Health Service, U. S. Department of Health, Education, and Welfare.

tion be restricted to children in the 5-through-9-year age group. On a nationwide basis, this group was at greatest risk. As of Oct. 12, the vaccine supply was approaching fulfillment of the demand for the 5-through-9-year age group. Almost 24 million cubic centimeters of vaccine had been released by the PHS—enough to give two injections to three-fourths of the 16 million children in this age category. Virtually all states had recommended to the service that the priority group be enlarged so that vaccinations might be extended to additional ages. This would expedite prompt use of the vaccine before its six-month expiration date.

In view of these facts, the National Advisory Committee recommended to the secretary that the priority age group be broadened. Within a range extending from birth through 14 years of age, states may establish priorities most closely related to their own pattern of disease incidence. They may also include pregnant women, whose susceptibility to poliomyelitis is about the same as that of 10-year-olds and twice the rate among other women of comparable age. This flexibility was recommended by the committee because of state variations in the incidence of poliomyelitis among the different age groups.

Because vaccine supplies still remain short of total demand, the secretary has recommended that each state initially extend its priority groups to embrace no more than five additional years of age outside the former 5-through-9-year priority. This is to enable the states to move, in an orderly way, into lower or higher age groups, according to their particular problems of incidence and severity of the disease. Although the federal priorities are not binding upon the states, they have been followed with few exceptions. State priorities are determined by state health departments, assisted by their advisory committees. With the broadening of the priority group, the allocation of vaccine among the states will now be based on their need for vaccine to complete the vaccination of children under 15 years and pregnant women. This involves an addition of approximately 36,500,000 persons to the priority group.

*Paralytic Poliomyelitis Attack Rates in Vaccinated and Unvaccinated Children**

State	Age Group Studied	Period Studied, 1955		Unvaccinated			Vaccinated			Reduction in Rates, %
		From	To	Population	No. of Paralytic Cases	Rate Per 100,000	Population	No. of Paralytic Cases	Rate Per 100,000	
California	6-8	6/15	10/15	431,000	43	10.0	395,000	13	3.3	67

Washington	5-9	5/15	10/14	190,179	40	21.0	69,123	4	5.8	72

* Summary of special studies from 11 states and New York City—preliminary reports received through Nov. 1, 1955. Data obtained from attachment to Poliomyelitis Surveillance Report no. 50, Nov. 10, 1955.

FINANCING

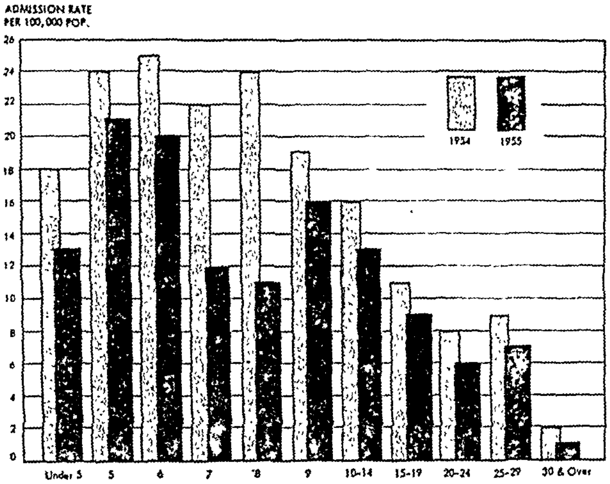
In order that poliomyelitis vaccine might be available to all the population as needed—and considering those who might be financially unable to obtain vaccine in their own behalf—17 states and 2 territories made available to their health departments a total of approximately 6 million dollars for the purchase of vaccine.

The federal government, likewise, has provided assistance. Shortly after licenses were issued to six manufacturers to produce and distribute the vaccine, President Eisenhower promised the American people that he would recommend a program that would assure that no child would be denied poliomyelitis vaccine because of inability to pay for it. Legislation to put into effect the administration's program was introduced in both houses of Congress. Other bills providing for federal sharing of the cost of vaccine and administration of the program were also introduced.

The Poliomyelitis Vaccination Assistance Act of 1955, passed in the closing days of the congressional session, authorizes grants to states for purchase of poliomyelitis vaccine, for planning vaccination programs within the states, and for conducting such programs through public agencies. The act expires Feb. 15, 1956. Congress appropriated 30 million dollars in grants for this program. These funds are available for obligation by states through Feb. 14, 1956. It is too early to predict whether an extension of the act will be requested—or in what form. Of the 30 million dollars appropriated, 25 million dollars was allotted among the states for purchase of vaccine. The allotment formula is based on eligible population (unvaccinated children under 20 years of age and expectant mothers) and per capita income. The remaining 5 million dollars is available for expenses connected with planning and conducting vaccination programs through public agencies, including the purchase of vaccine. No state matching is required for either portion of the allotment. The Public Health Service may furnish vaccine in lieu of cash to a state, if the state so requests. Twenty states have requested that the service purchase vaccine for them in lieu of cash payments.

In addition, congress appropriated $4,500,000 as a *supplement to the General Health Grant of the Public* Health Service. These funds are earmarked and may be used only for planning and operating the intrastate vaccine distribution system and for planning and conducting public vaccination programs. Funds from this appropriation are available through June 30, 1956.

As a condition to receiving payments under the Poliomyelitis Vaccination Assistance Act, state plans must contain assurance that no means test will be imposed for poliomyelitis vaccination services provided through public agencies. This assurance is required for all programs conducted by public agencies regardless of whether the vaccine is purchased with federal funds or with state or local funds. The restriction in the act against use of a means test as a condition of eligibility does not apply to the administration of poliomyelitis vaccine by private physicians or nonprofit organizations when they are not acting as employees or agents of a public agency—even though the vaccine may have been purchased with federal grant funds.



Number of persons with acute poliomyelitis admitted to hospitals per 100,000 population with onset of cases June 26-Sept. 17, 1955, and June 20-Sept. 10, 1954 (based on tabulation of hospital admissions supplied by the National Foundation for Infantile Paralysis).

Because of individual needs and situations, there is considerable variation among the state plans with respect to the division of vaccine between public agency and commercial purchasers. Some states have requested that their entire allotment go to public agencies; some that all go through normal distribution channels to retail druggists and physician; and some that the distribution be split. On a national basis, the vaccine released for sale has been about equally divided between public agencies and commercial purchasers.

AVAILABILITY

The fact that some states are purchasing their entire allotments of vaccine with tax funds does not mean that this vaccine will not be available to physicians for use in their private practices. Most state plans indicate that details for administration of the vaccine are being developed locally through the cooperative efforts of local medical societies and health departments. Some counties and cities will hold public clinics; some will rely chiefly on private physicians; and many will make the vaccine available both in public clinics and to private physicians.

Since April 12 (and including vaccine released subsequent to Oct. 12) a total of almost 25 million cubic centimeters of vaccine have been released by the PHS —13,500,000 for the National Foundation for Infantile Paralysis, 11,000,000 for interstate distribution, and 500,000 released before voluntary controls were put into effect. Over 6,500,000 children have been reached by the foundation-supported program, which provides two injections for children who were in first and second grades in the Spring of 1955. The vaccine needs of this program have now been essentially satisfied.

It is impossible to predict with any certainty the availability of future vaccine supplies. On the basis of current output, however, the Public Health Service expects that if the states concentrate on the next most susceptible groups—within the five additional years recommended —it will be possible to give these groups some protection by the start of the next poliomyelitis season.

The Public Health Service is continuing to receive encouraging reports as to the safety and effectiveness of the vaccine now being released for use. The Poliomyelitis Surveillance Unit of the Public Health Service, with headquarters at the Communicable Disease Center in Atlanta, Ga., is serving as a clearing-house for a nationwide study to determine the effectiveness of poliomyelitis vaccine as used this year and to report the experience of children vaccinated in the field trial. All state and territorial health departments, more than 40 virus laboratories, the National Office of Vital Statistics, the National Foundation for Infantile Paralysis, and others are participating in the study.

RESULTS OF USE

The results of this year's use of poliomyelitis vaccine cannot be stated precisely at the present time. Only partial, preliminary reports on this season's occurrence of poliomyelitis throughout the nation have been received. There is always some lag in reporting, and many weeks are needed to verify diagnoses and to determine the extent of paralysis in reported cases.

Although final conclusions cannot be drawn, the first "returns" are very favorable. The number of reported cases of poliomyelitis, paralytic and nonparalytic, among 7 million vaccinated children throughout the United States is now running 25% to 50% below the incidence expected without vaccination in the same age groups. All states and territories are participating in this part of the study. During the first month or two following injections, about as many cases were reported in vaccinated children as were expected. But after the second month, the frequency was substantially lower. Also, strong evidence of lessened severity became apparent after the second month, when reported cases among vaccinated children became predominantly nonparalytic.

Special studies are being carried out in nearly half of the states to measure the poliomyelitis experience of children 5-10 years of age. Early reports from 12 areas show that paralytic attack rates among vaccinated children are strikingly lower than among unvaccinated children of the same ages. Differences in rates for the several states range from 55% to 91% (table). In epidemic areas, particularly in New England and Wisconsin, the infrequency of paralytic cases among vaccinated children is notable. Especially intensive studies are being conducted in these states. In these high-incidence areas, the immunity of vaccinated children has been put to the severest test. It is expected that these studies in epidemic areas will provide the most definitive evidence regarding the effectiveness of the vaccine this year. The Massachusetts study, in particular, should yield a wealth of significant data. The number of paralytic cases among children vaccinated in the 1954 field trial, with or without "booster" injections this year, is too small for evaluation as yet. The rarity of paralytic cases in this group, however, is outstanding, so far. Thirty-three states are submitting to the Poliomyelitis Surveillance Unit current reports of poliomyelitis cases by single years of age. These figures, when compared with similar figures from 21 states for 1952, show reduction in the incidence of paralytic poliomyelitis among 7- and 8-year-old children. This early evidence is significant because the use of poliomyelitis vaccine has been restricted this year chiefly to these age groups.

A tabulation of routine hospital admissions for acute poliomyelitis by the National Foundation for Infantile Paralysis for 1954 and 1955 gives further support to these early leads (figure). In 1954, between June 20 and Sept. 10, the admission rate climbed to a peak at ages 4-8 years and then followed a gradual downward trend with advancing age. For the comparable period in 1955, on the other hand, admission rates peak at ages 5 and 6 years, then drop markedly among 7- and 8-year-olds, and rise again at age 9 years. Thus the vaccine appears to have caused a distinct decrease in 1955 poliomyelitis admission rates for 7- and 8-year-olds. This, of course, is the age group reached by the vaccination program supported by the National Foundation for Infantile Paralysis. Again, the tentative nature of these data must be stressed. As mentioned before, they are based on preliminary, and as yet incomplete, reports of the experience of children of limited age groups. But no major departure from these favorable trends is anticipated, although the precise rates may change.

RADIOLOGICAL DIAGNOSIS OF RETAINED SURGICAL SPONGES

Herbert M. Olnick, M.D., Macon, Ga., H. Stephen Weens, M.D.
and
James V. Rogers Jr., M.D., Atlanta, Ga.

As long as nonabsorbable materials are used in the manufacture of surgical gauze, the specter of the retained sponge or laparotomy pack will continue to be a nightmare to the practicing surgeon. With surprising ease difficult to appreciate, an operative instrument or pack may disappear from sight while the mind and hands of the operator are preoccupied with the operative procedure. Such unfortunate accidents are known to have occurred even with skilled surgeons working under the most favorable conditions. The relative paucity of reports on the subject is easy to understand in view of the stigma and medicolegal liability implied in the admission of the technical oversight.

SURGICAL PATHOLOGY

The clinical and radiological features of the retained sponge can be understood in the light of the surgical pathology. The body reacts to the foreign substance by inflammation that may be of an aseptic fibrinous type, producing adhesions and encapsulation, or may be exudative in nature, with abscess formation, with or without secondary bacterial invasion. The development of an abscess represents an attempt by the body to extrude the foreign material, either externally or into a hollow viscus. A sinus tract or fecal fistula may develop, which can heal only after spontaneous expulsion or surgical removal of the irritant. Abscesses comprise most of the cases in the early postoperative period, since they produce urgent clinical symptoms. Fever, anemia, and weight loss to a degree simulating cachexia from advanced cancer may be present.

Low-grade inflammation creates adhesive encapsulation and produces obstructive symptoms, usually after several months, although this may occur in the immediate postoperative period. The fibrous capsule with dense inflammatory adhesions may produce a palpable mass. In rare instances, calcium may be deposited in the fibrous capsule regardless of whether the foreign material is in contact with intestinal or urinary contents. While all of the reticular spaces of the sponge may be filled with just fluid or gas, later the entire sponge may become organized into a solid mass.

RADIOLOGICAL FEATURES

Our paper is not intended to expand upon the classic work of Crossen and Crossen[1] who have discussed in great detail the clinical, pathological, and statistical features of retained foreign bodies. These authors appreciated many years ago the potential value of the x-ray examination and discussed some of the earlier efforts to incorporate radiopaque material in gauze. Our paper purports, by means of illustrated case reports, to enlarge upon the seldom-described radiological features that may be of considerable importance in the proper recognition of these retained foreign bodies, whether they be opaque or nonopaque.

While in some cases there is no roentgen evidence, in most cases one or more signs will be seen. The most im-

Read before the Section on Radiology at the 104th Annual Meeting of the American Medical Association, Atlantic City, June 7, 1955.

Dr. I. Berger of the Veterans Administration Hospital, Chamblee, Ga gave permission to report the case illustrated in figure 3.

[1] Crossen, H. S., and Crossen, D. F.: Foreign Bodies Left in the Abdomen: The Surgical Problems, Cases, Treatment, Prevention: The Legal Problems, Cases, Decisions, Responsibilities, St. Louis, C. V. Mosby Company, 1940.

portant clue is the presence of the radiopaque insert that most operating rooms are now utilizing in their surgical gauze. The x-ray detectable sponges and laparotomy packs commercially available contain a radiopaque insert made of barium sulfate and inert plastic materials.

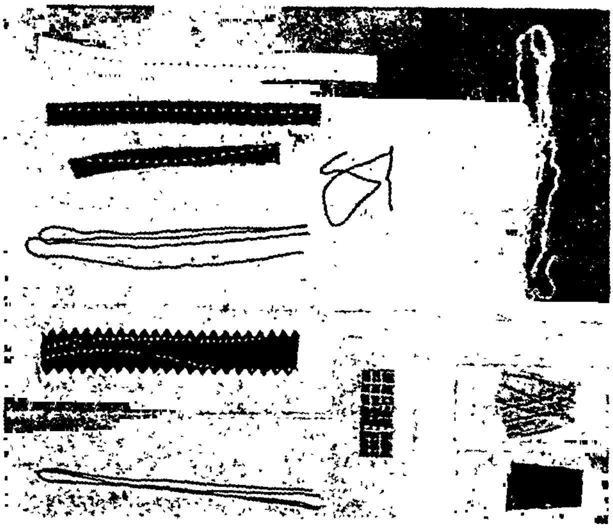

Fig. 1.—Radiographic appearance of commercially available radiopaque inserts, grouped according to manufacturer. Those on the left have superseded *those shown on the right.*

The morphology of the inserts differs with each manufacturer. However, there are only two types: the monofilament or thread type, and the ribbon type. Figure 1 illustrates the x-ray appearance of the original and current inserts that are or have been commercially available. It must be appreciated that the appearance of the individual tell-tale sign will vary with folding and twisting of the sponge. The barium of the older type inserts tended to diffuse or collect into irregular form after long-continued retention in body tissues. Gastrointestinal studies tend to obscure the radiopaque inserts, since the fiber pattern resembles that of the mucous membrane of the intestine.

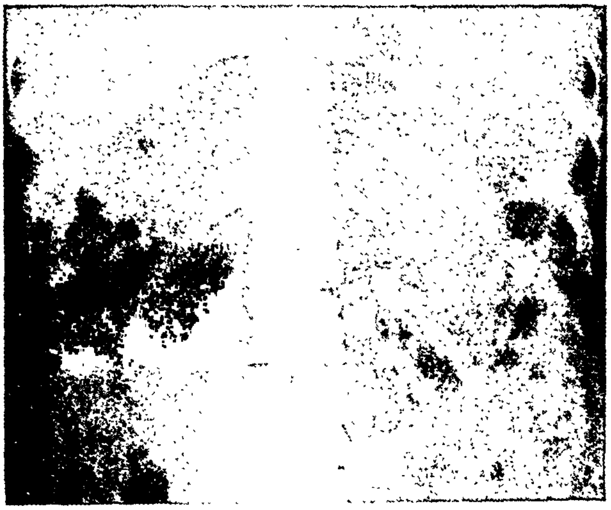

Fig. 2.—Obstructive symptoms six weeks after cesarean section. Note whirl-like gas pattern surrounding the filiform opaque insert. Operation *revealed laparotomy pack totally within the jejunum.*

The sponge is also recognizable by the presence of gas trapped between the fibers, *giving a characteristic* whirl-like configuration (fig. 2). In some instances, the gas is intestinal in origin, and in other instances it is formed by bacteria in an abscess. A palpable mass corresponding to the foreign body and the surrounding tissue reaction is often sharply outlined on the roentgenogram (fig. 2). If adherent to the parietal peritoneum, it will be fixed. If encapsulated entirely by the mesentery, it may be freely movable. Our series contains one case in which the sponge showed calcification (fig. 3). This is a rare manifestation. Crossen and Crossen stated that calcification occurred only when the sponge was in contact with the lumen of either the intestinal tract or the urinary tract. However, cases of calcification of retained sponges lying entirely within the peritoneal cavity have been reported.[2] The case illustrated in figure 3 *is one such instance.*

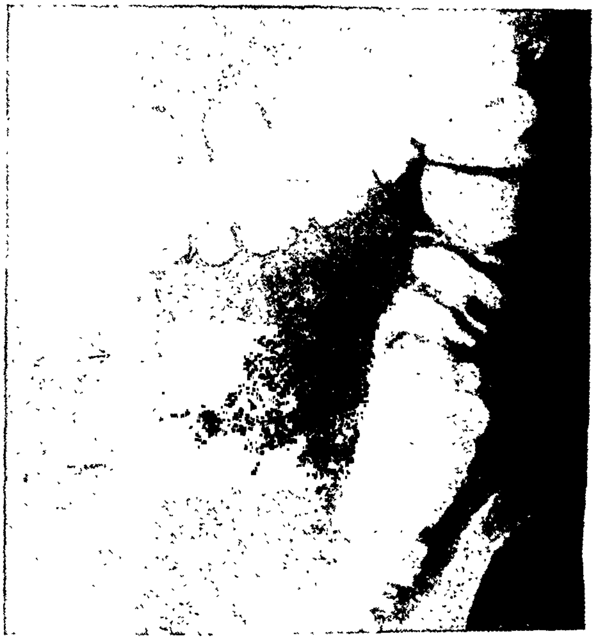

Fig. 3.—Roentgenogram taken 14 years after appendectomy. The patient had abdominal pain, nausea, and tenesmus. Note calcified mass overlying left side of L-4 and L-5 (arrows). Operation showed a degenerated sponge enveloped in scar tissue lying at the mesenteric border of small intestine.

If a sinus tract is present, the sponge may be visualized *indirectly by the injection of iodized oil.* This method of radiographic diagnosis was mentioned in a book by Crossen and Crossen, who cited two instances [3] from the literature wherein the diagnosis was made by this method. We were unable to find any recent cases in which use of this method was reported. The iodized oil enters the depths of the tract outlining the large pocket and fills the meshwork of the sponge, corresponding to its fiber structure (fig. 4). Injection of radiopaque oil was of diagnostic value in three cases in our series. In a similar fashion, barium administered for a gastrointestinal x-ray examination outlined the silhouette and interstices of a laparotomy pack within the small intestine.

Any instance in which a patient after operation has an unexplained mass, sinus tract, or intestinal obstruction should immediately put the radiologist on the alert for the possibility of a retained sponge. While most sponges nowadays have the opaque insert, patients operated on before the era of radiopaque sponges may still present themselves after many years to become today's diagnostic problem. Further, detection of the opaque insert may be hindered by overlying bony structures and by an atypical appearance of the insert itself.

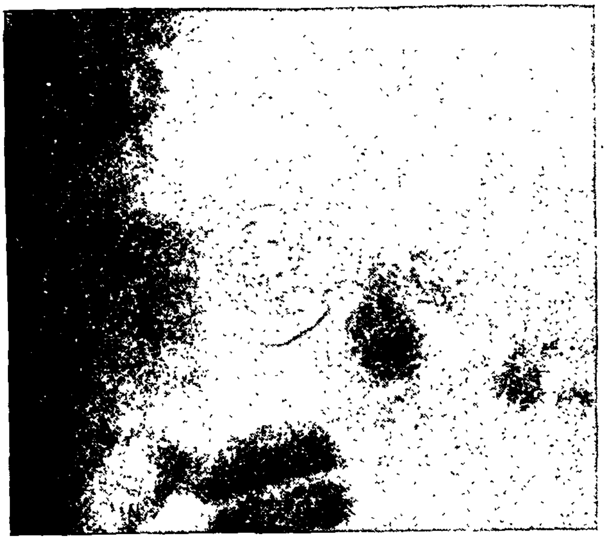

Fig. 4.—Roentgenogram taken after injection of iodized oil (Lipiodol) into retroperitoneal sinus tract outlining meshwork of sponge. Patient had sinus tract for 18 months after nephrostomy. After removal of sponge, the sinus promptly healed.

SUMMARY AND CONCLUSIONS

The following features in the recognition of retained sponges and laparotomy packs should be considered. 1. The radiopaque insert may be readily demonstrated by appropriate radiological studies. One should recognize, however, that the pattern of the insert may be distorted by folding, twisting, and disintegration. Also, a gastrointestinal pattern may be simulated by the appearance of the insert. 2. Gas formation in the sponge mesh may produce a whirl-like pattern that is detectable on radiological examination. 3. In many instances, the sponge may form a well-circumscribed mass by encapsulation. 4. In rare instances, calcification of this mass may take place that may be demonstrated on radiological examination. 5. In cases of sinus tract development, injection of opaque material into the sponge mesh identifies the retention of the foreign body. 6. If the foreign body ruptures into the intestinal lumen, a bizarre pattern may be demonstrated on gastrointestinal examination. While such evidence is not present in every case of this serious surgical complication, careful attention to the radiographic manifestations described here permit, in many instances, accurate diagnosis.

EIGHT PATIENTS WITH ADRENAL CORTICAL HYPOFUNCTION SURVIVING MORE THAN FIFTEEN YEARS

Leonard G. Rowntree, M.D., Miami, Fla.

The purpose of this communication is to report the unusually prolonged survival time in several cases of adrenal cortical hypofunction (Addison's disease). Eight have survived from 15 to 18 years. The cases here reported fall into two categories. 1. In three early cases, recorded in 1940, the patients survived 15 years or more. Judged by present-day standards, their treatment may be regarded as inadequate in several respects, though in two of the three cases Swingle's cortical extract (noncommercial adrenal cortical hormone with a daily increment of sodium as chloride citrate and bicarbonate) and adequate sodium were used after 1933. 2. In eight consecutive cases of adrenal cortical hypofunction, the patients were placed on a regimen of Swingle's cortical extract between 1933 and 1940. Their treatment, I believe, has been adequate and highly satisfactory. Since all the cases have been previously reported in considerable detail, only thumbnail sketches are presented here.

REPORT OF CASES

Case 1.—A 44-year-old man had a diagnosis of adrenal cortical hypofunction made at the Mayo Clinic, Rochester, Minn., in 1917. It was considered to be secondary to tuberculosis of the adrenal glands; this was finally confirmed at autopsy in 1935. The case was remarkable not only for its long survival of 18 years, but also because the patient ran the gamut of many forms of therapy. He was one of the first cases in which diminution of the blood and plasma volume were recognized as a factor in the crises of the disease, and one of the first cases in which bilateral calcification of the adrenals was demonstrated clinically by x-ray and confirmed at autopsy.

Case 2.—A 37-year-old man was admitted to the Mayo Clinic in 1926 with syphilis and adrenal cortical hypofunction considered to be of syphilitic origin. X-rays of the adrenal glands revealed no calcification. The course of the disease was somewhat milder than usual. He was followed at the Mayo Clinic for a number of years and was reported to be alive and working 15 years later. Adrenal cortical hypofunction had developed in 1924, and the patient reported to me by letter in 1939, at which time he was taking an extra 8 gm. of salt daily and cortical hormone by injection once weekly. Since 1939 I have had no further contact with this patient.

Case 3.—A 26-year-old man entered the Mayo Clinic in 1922, complaining of great weakness and weight loss. He exhibited the typical pigmentation of the skin, lips, and buccal mucosa, together with many black freckles. This patient had developed a bleeding duodenal ulcer in 1921, for which he was kept in bed for eight weeks. Subsequently he developed the typical manifestations of adrenal cortical hypofunction. His pigmentation was extreme and was diagnosed by dermatologists as being caused by adrenal cortical hypofunction. This patient did exceptionally well on the Muirhead regimen (epinephrine and suprarenal cortex). In 1931 his family physician wrote me that recovery was complete and the patient was in perfect health and free of any evidence of adrenal cortical hypofunction. In my opinion this represents an arrested case or an actual cure.

Fortunately I saw the patient personally subsequent to his recovery. His pigmentation had completely disappeared, his blood pressure and weight were normal, and survival was 17 years.

The second group is comprised of five patients belonging to a series of eight given Swingle's cortical extract and extra sodium between 1933 and 1940. Five of these patients (60%) survived 15 years, of whom four are still living after 15 years, with an average survival of nearly 17 years. Four of the eight are dead, surviving 9, 10, 11, and 15 years respectively. A word should be said about those who died. In three of the cases two succumbed after undue exposure and one died through failure to keep himself supplied with medication. The fourth died of diffuse vascular disease and without adrenal insufficiency. This patient was regarded as having an arrested case and was considered actually cured of adrenal cortical hypofunction.

Case 4.—A 50-year-old man was referred to me in 1933 with the marked and unmistakable features of adrenal cortical hypofunction. His response to Swingle's cortical extract and extra salt was miraculous. For 15 years he continued to work daily as a chief executive. In December, 1948, he was exposed to a blizzard for which he was not prepared, walking for some miles in thin shoes and light clothing. After reaching home, chilled, he collapsed. His local doctor stayed with him throughout the night, but before dawn the patient went into a severe adrenal cortical hypofunction crisis and died. Had he not been so exposed he might have lived years longer. Autopsy confirmed the diagnosis of adrenal cortical hypofunction of tubercular origin.

The following four patients are still living and in excellent clinical condition. All are receiving active treatment.

Case 5.—A 32-year-old woman became ill with the "grippe" in 1937, after the birth of her second child. I saw her in consultation while she was hospitalized in Easton, Pa. Her pigmentation was marked, her weakness extreme, and her weight loss considerable. The diagnosis was unmistakably adrenal cortical hypofunction, and she was placed on a regimen of large doses of cortical hormone, together with extra salt and vitamin C. This was continued for six years with excellent results. During World War II the supply of cortical extract became limited so she was given implantations of pellets that have been continued for more than 10 years. Her pigmentation was marked. She has kept in touch with me intermittently throughout the years, and on her last visit two years ago, she appeared normal in every way and was living the life of a normal housewife.

Case 6.—A 21-year-old man was seen in the Delaware County Hospital near Philadelphia. He was in a serious crisis of adrenal cortical hypofunction and in a state of considerable mental derangement. He was given large doses of cortical extract and extra salt daily, a regimen he has continued for 15 years. He now leads the normal life of a normal young office man. He has had two minor crises, each of which kept him in bed for 10 to 14 days. Euphoria has been striking; however, he has remained thin, weighing 124 lb. (56.3 kg.); his systolic blood pressure has remained low, rarely exceeding 90 to 100 mm. Hg; and his pigmentation, though slight, has continued. With the hope of boosting his blood pressure, corticosterone was administered once weekly without noticeable results. Lately he has also taken 25 mg. of cortisone daily by mouth, also. This he claims has given him additional "pep." The patient was last seen three months previous to this writing, at which time his mother stated that his illness actually started before December, 1939, and that it had continued unchanged until I saw him in June, 1940. This patient considers himself well, and he adheres strictly to his regimen.

Case 7.—A 31-year-old woman was seen in my office in Philadelphia in June, 1939. Her clinical picture was typical of adrenal cortical hypofunction—weakness, exhaustion, nausea; vomiting, marked loss of weight, striking pigmentation, and hypotension. For 12 years she was treated exclusively with Swingle's cortical extract and additional salt and did well except for infrequent and minor crises. During the years she developed some generalized arthritis that gave her considerable distress. This in part led to some changes in her management—the use of pellets and of cortisone and small doses of testosterone, along with infrequent and small injections of the cortical extract. When last seen a few months ago her clinical condition was excellent, the pigmentation and the arthralgia were markedly decreased almost to the vanishing point, and the euphoria was striking.

Case 8.—A 32-year-old man came to my attention in May, 1937, when his illness had been diagnosed as adrenal cortical hypofunction by his doctor in Albuquerque, N. Mex. He was critically ill at that time, and I advised against moving him but conferred with his physician by phone and letter. He was treated with the cortical extract and a daily increased increment of salt. In December, 1937, he consulted me in my office, at which time the diagnosis was confirmed. The patient did so well on treatment that during the following summer, on his own initiative, he reduced the medication to a minimum, whereupon he experienced a serious crisis and had to be brought back to the hospital in an ambulance. Following this, for 15 years the regimen has been continued religiously. Some three years ago he raised the question of treatment with cortisone. It was gradually added to his regimen and proved highly successful. The patient is still well, 18 years later.

COMMENT

My major reason for continuing this regimen has been my fear of discontinuing it. Human lives were at stake. To me this regimen seemed the best and the safest available. The salt treatment alone in adrenal cortical hypofunction proved ineffective, dangerous, and inexcusable. Many patients also need desoxycorticosterone acetate. In one series of cases known to me, six of the seven patients treated by pellet implantation died, the longest survival in the group being seven years. In this series of cases all the patients were living after 9 years, with an average survival of more than 10 years. This experience engendered confidence in the regimen and a strong reluctance to abandon it. Two patients recovered. Swingle's suprarenal cortical extract appears to be a fortunate mixture of adrenal hormones, the active principles being so balanced as to be generally effective in meeting the metabolic needs in cases of adrenal cortical hypofunction and yet devoid of any demonstrable toxic effects in any and all fields of metabolism concerned. I believe that this preparation may closely approximate the physiological mixture of principles secreted by the suprarenal glands, for nature rarely depends wholly on one hormone.

The chief and only drawbacks to Swingle's preparation have been its unavailability to the sick and its high cost. All the solutions I have used were prepared and standardized by Dr. Swingle in his own laboratory. While the cost has been reduced to a minimum, it is still beyond the reach of many patients. The results in this small series of cases indicate that the additional cost of treatment is entirely justified. In the light of these results it would seem desirable that some way be found of making this preparation more generally available and at a cost that is within the reach of the average patient.

While the specific regimen described is the chief factor in the prolonged survival of these patients, other factors undoubtedly enter into the picture, such as improved understanding of the disease and of the function of the adrenal glands, improved sanitation, better living conditions, the use of vitamins, the better care of patients with tuberculosis, and the control of intercurrent infections by antibiotics. Singly or collectively, none of these factors can be considered more than contributory to survival. However, the prolonged survival times here recorded (no deaths under 9 years, and five of eight patients surviving 15 to 18 years) suggest that this extract may have special virtues in prolonging life. It also suggests that it warrants further study.

SUMMARY AND CONCLUSIONS

The survival time in cases of adrenal cortical hypofunction (Addison's disease) has generally been materially prolonged through modern methods of treatment. Eight of my patients have survived for over 15 years. This covers an experience in the treatment of more than 150 patients seen during the last 35 years. In a series of eight consecutive patients (1933-1940) treated with Swingle's suprarenal cortical extract and with an adequate intake of salt daily, all survived for at least 9 years, seven survived 10 years or more, and five survived from 15 to 18 years. Two patients recovered. In several patients recourse was made to other adrenal preparations; two received pellet implantations late in the course of their disease and two were given small doses of cortisone. The survival time in this series sets a new record in adrenal cortical hypofunction though the number of cases concerned is admittedly small. The results here presented suggest the desirability of finding ways and means to make Swingle's suprarenal cortical extract more generally available and at a lower cost or to compound some balanced mixture of adrenal hormones that will serve as an effective and inexpensive substitute.

1342 du Pont Bldg.

Housewives' Dermatitis.—[This] is one of the commonest of occupational hazards. All soaps and detergents degrease the skin to some extent, in proportion to their cleaning efficiency. The results are essentially the same, whether the skin fat is emulsified and rinsed off or whether it is removed by solution. The denuded keratin becomes exposed to the action of the cleaner, for a shorter or a longer time, depending upon the ability of the sebaceous glands to replace the lost fat and on the emulsifying and spreading properties of the sweat. . . . Once dermatitis has developed, avoidance of further exposure is essential, but at this stage rubber gloves are rarely tolerated. Mild cases recover with the use of bland applications; but in the severest forms recovery may take months or the dyskeratotic process may persist indefinitely because the germinal cells have been damaged. No cream can give back to denatured basal cells the power to form a normal keratinous layer. . . . Toilet soaps have a beneficial effect on the skin. . . . When the skin is cleaned with soap and water an adsorption layer of soap is formed and is converted in less than an hour into a layer of free fatty acids which cling tenaciously to the skin. These fatty acids have beneficial (bactericidal) effects as well as very occasional harmful (allergenic) effects. Toilet soaps rarely cause dermatitis although they may aggravate existing dermatitis as, for that matter, may water itself.—B. Russell, M.D., Advances in the Treatment of Skin Diseases, *The Practitioner*, October, 1955.

CLINICAL NOTES

FATAL POISONING WITH SODIUM FLUOROACETATE

REPORT OF A CASE

John L. Brockmann, M.D.
Arthur V. McDowell, M.D.
and
William G. Leeds, M.D., Hartford, Conn.

Extensive chemical research carried out in recent years has produced a rodenticide, sodium fluoroacetate, which has been found to be very effective and extremely toxic. Sodium fluoroacetate, or "1080" as it was called during the investigation period, is said to be one of the most noxious substances known, since it is toxic to all mammals, man included.[1] Sodium fluoroacetate was first reported by Kalmbach.[2] With this poison rat control can be much more easily and effectively carried out than ever before; however, because of its extreme toxicity (three teaspoons of the watered solution used for rats is sufficient to cause death in the adult human being) many necessary precautions have been taken in its employment and administration. It is distributed only to qualified members of governmental agencies and to properly insured and licensed pest control agencies and operators. In addition, strict regulations are imposed upon its use, and standard procedures are outlined in attempts to prevent the inadvertent poisoning of human beings and domestic animals. A technical bulletin is published by the manufacturers with instructions for usage.[3]

The drug is a colorless, odorless, and tasteless water-soluble salt. As a rat poison, it is prepared by dilution to one part in 300 or 500 parts of water. The drug is equally effective as a poison regardless of mode of entry. It may be absorbed through the intact skin but not readily; however, it is easily absorbed through cuts and abrasions.[4] It is rapidly absorbed in the gastrointestinal tract and may also be absorbed through the lungs by breathing dust containing the poison.[4] The theory has been advanced by several writers that sodium fluoroacetate acts as a metabolic poison producing its lethal effects, not as a free fluoride, but as an intact molecule.[4] The exact mechanism has not, as yet, been uncovered, but it is felt that sodium fluoroacetate competes in reactions where acetate normally takes part. It has been suggested

---

From Hartford Hospital. Dr. Brockmann is now a lieutenant (j.g.) in the U. S. Naval Reserve.

Dr. Abraham Stolman, Toxicologist for the state of Connecticut, made the determinations of fluoride content. The Pathology Department of Hartford Hospital (particularly Dr. George McAdams) made the postmortem examination and synopsis of the findings.

that this interference with acetate metabolism may cause a piling-up of citrate.[5]

Chenoweth and Gilman have studied extensively the reactions produced by sodium fluoroacetate in animals and have classified the animals in groups according to the reactions brought about in them by the agent.[6] The organ systems affected are chiefly the cardiorespiratory and central nervous systems. Briefly, the classification includes the following: group 1, in which the action is a cardiac one, with death due to ventricular fibrillation; group 2, in which there is both a cardiorespiratory and central nervous system response, with death in respiratory failure during convulsions or ventricular fibrillation; group 3, in which the primary effect is on the central nervous system, with no cardiac abnormality; and group 4, in which there is an atypical response, including bradycardia and respiratory depression. In man, sodium fluoroacetate has been found to produce a mixed response, with elements of cardiorespiratory and central nervous system damage similar to that produced in monkeys.[7]

According to the available literature, there have been 22 known cases of poisoning with sodium fluoroacetate, 16 of which were fatal [4]; however, only 2 cases have been reported in the medical literature to our knowledge. One of these was fatal, the other was not. Gajdusek and Luther in 1950 [1] reported a case of nonfatal poisoning in a 2-year-old infant, and in 1952 Harrisson and others [7c] reported a case of fatal poisoning. In each of these articles, the experimental and toxicologic literature was thoroughly reviewed, and the references are complete. Thus far there has been no case reported in which the exact quantity of the poison taken was known. Careful calculations in the cases mentioned have given approximations of the amount ingested. It has been estimated that about 5 mg. per kilogram of body weight is lethal to man. In the case reported by Harrisson and others a minimum of 6 mg. per kilogram was ingested.[7c] In this paper a case of fatal poisoning with sodium fluoroacetate is reported. We feel that this case is of particular interest because the patient lived for five days after ingesting the poison and extensive laboratory work was therefore possible. A postmortem examination with analysis of the organ contents was also obtained.

REPORT OF A CASE

A 17-year-old boy, son of a professional rat exterminator, entered the emergency room of our hospital at 4 a. m., Jan. 1, 1954, and told the nurse that he had ingested a solution of sodium fluoroacetate. The amount ingested could not be determined accurately, but a previously unopened 8 oz. can of the material was found in his room half empty. Apparently, the boy had dissolved a large amount of the poison in water and swallowed the solution, after which he promptly vomited. He stated that he had noted almost immediate epigastric pain. He came to the hospital about 45 to 60 minutes after this incident. At the time of admission the patient was alert and responsive but complained of epigastric pain. A gastric lavage with starch water and magnesium sulfate was carried out immediately. During this procedure, the patient gradually became more and more unresponsive, and by 5:20 a. m. he was comatose. A half hour later he had a grand mal convulsion associated with fecal incontinence.

Physical Examination.—Blood pressure was 110 mm. Hg systolic and 70 mm. Hg diastolic. The pulse was irregular at a rate of 72 per minute, and the respirations were 16 per minute. The patient was in deep coma, unresponsive to painful stimuli. The skin was warm and dry. There was dusky cyanosis of the nailbeds and lips. The pupils were constricted but reacted normally to light. The neck was supple. Lungs were completely clear throughout. Examination of the heart revealed the point of maximal impulse to be well localized in the fifth left intercostal space medial to the midclavicular line. There was a normal sinus rhythm, with frequent ventricular premature beats (about 16 to 20 per minute). The heart tones were of poor quality. No murmurs were heard. The abdomen was negative. Neurological examination revealed the cranial nerves to be intact, as far as could be determined. The abdominal reflexes were absent, and the Babinski sign was present bilaterally. There were frequent chewing movements of the jaws. The remainder of the examination was not remarkable. An electrocardiogram obtained at this time showed the rate to be 72 and showed occasional ventricular premature contractions, a prolonged Q-T interval, the QRS complex negative in lead 1, the T wave negative in leads 2, 3, and aVF, and the T wave notched in leads V_3, V_4, and V_6. This was interpreted as showing right axis deviation, ventricular premature contractions, and evidence of diffuse myocardial abnormality.

Drug Therapy.—The patient was given oxygen by nasal catheter and procainamide (Pronestyl) hydrochloride, 500 mg. in 500 cc. of 5% dextrose in water, intravenously. During the next four hours, the heart sounds improved in quality and the rhythm was completely regular. Phenobarbital sodium or amobarbital (Amytal) sodium was used to control the signs of cortical irritability. Eight hours after admission, the patient vomited some dark brown material, which gave a chemical reaction for blood by the benzidine test. Examination at this time revealed that the cyanosis had disappeared and the vital signs were normal. The skin was flushed. The heart seemed dilated as evidenced by a very diffuse point of maximum impulse, 2 or 3 cm. outside the midclavicular line. Coma persisted. The neurological signs mentioned above were again demonstrated.

During the next 12 hours, the patient became very restless, thrashing about in bed. There were frequent episodes of severe carpopedal spasm, while at other times all the muscles of the body became very spastic and it seemed that another grand mal seizure was imminent. These periods of neuromuscular hyperactivity were temporarily controlled by intravenous therapy with calcium gluconate, 10 cc. of a 10% solution. On the morning of the second day, acute pulmonary edema supervened. The patient was digitalized with lanatoside C. The pulmonary edema cleared readily, but coma persisted. The pupils were small and fixed to light, and the respiratory rate increased to 40 per minute. Blood pressure was 100/70 mm. Hg and the pulse 160 per minute and feeble. An electrocardiogram taken at this point revealed supraventricular tachycardia and the evidences of diffuse myocardial abnormality noted above. There were no premature beats. During the ensuing four hours, the pulse rate rose to 180 per minute and the blood pressure dropped to 84/0 mm. Hg. Cheyne-Stokes respirations became evident, and the heart became further enlarged. Suction of the upper respiratory tract had to be carried out frequently, and an endotracheal tube was inserted. Because of the hypotension, levarterenol (Levophed) bitartrate therapy, 4 mg. in 1,000 cc. of 5% dextrose in water, was started by intravenous drip. This produced no appreciable effect on the blood pressure, although the pulse slowed a little and seemed stronger. At 11:30 p. m. of the second day, examination showed no change in the physical findings, except that the pupils once again reacted to light. Levarterenol bitartrate therapy was discontinued, and procainamide hydrochloride, 500 mg. in 500 cc. of 5% dextrose in water, was again administered intravenously. Mephentermine (Wyamine) sulfate therapy, 15 mg. every two hours by intramuscular injection, was tried. Calcium gluconate was given repeatedly to control the carpopedal spasm.

Condition of Patient.—On the third day the clinical picture and forms of therapy remained unchanged except for a further drop in blood pressure to the point of being unobtainable. Another electrocardiogram showed no important changes when

7. (*a*) Footnote 1. (*b*) Footnote 4. (*c*) Harrisson, J. W. E., and others: Acute Poisoning with Sodium Fluoroacetate (Compound 1080), J. A. M. A. **149**: 1520-1522 (Aug. 23) 1952.

compared with the previous ones, except for the addition of digitalis effect. The temperature continued to rise and reached a maximum of 104.6 F (40.3 C) late on the third day. On the fourth hospital day there was a tremendous increase in the amount of tracheobronchial secretions, which necessitated almost constant suctioning. On this day it was decided to alternate 5% alcohol in 10% dextrose in water intravenously with procainamide hydrochloride intravenously. This treatment was carried on through the fifth day, when the patient's condition seemed to improve a little. The blood pressure was obtainable at 100/60 mm. Hg, though the pulse remained rapid (180 per minute) and feeble. The heart sounds remained "flabby" in character. The extremities became warmer and had a good color. The muscular and carpopedal spasms decreased remarkably after the start of intravenous therapy with alcohol. On the night of the fifth day, the tracheobronchial secretions became so copious and tenacious that an adequate airway was impossible without a tracheostomy. This procedure was therefore carried out. Thick yellowish-white mucoid material was suctioned from the lower trachea, and the airway immediately sounded clear and dry. Examination of the lungs at this time revealed them to be well aerated throughout. Coma, rapid and feeble heart action, hypotension, the neurological signs noted above, and a good urinary output remained the principal features of the clinical course, together with a steadily rising temperature. At 3 a. m. on Jan. 6, 1954 (the sixth hospital day), the temperature reached 108 F (42.3 C) in spite of all measures to reduce it. From this point on the patient's respirations became extremely labored and rapid, the blood pressure once again was unobtainable, and the pulse increased to such a rapid rate that it was impossible to count it with any degree of accuracy. At 8 a. m. on Jan. 6, the patient died.

Postmortem Examination.—Postmortem examination revealed mediastinal emphysema, obvious and moderate in amount. The lungs were heavy (right 950 gm., left 750 gm.), edematous, and congested, but there was no frank consolidation. The bronchi were hemorrhagic but without exudate. Hemorrhagic-appearing mucosa was noted in the stomach but not in the esophagus. The spleen weighed 320 gm. and was red in color and firm to the touch. The right kidney contained a 2 mm., red-yellow area just beneath the surface. Other than congestion, the kidneys were normal. Crepitation could be felt and air bubbles could be seen in the adventitia of the aorta and immediate branches. The brain weighed 1,600 gm. and showed marked edema, with flattening of sulci and upward herniation of the cerebellum through the tentorium. Culture from the heart blood showed a moderate growth of hemolytic Micrococcus pyogenes var. aureus, coagulase positive. The remaining organs were grossly unremarkable.

Microscopic examination of the esophagus showed denudation of the epithelium here and there, with a coagulation necrosis present and minimal acute inflammatory reaction. The stomach mucosa was intact and essentially not remarkable. The lungs revealed a striking bronchopneumonia, with marked alveolar hemorrhages, congestion, and small clumps of bacteria. The brain contained small perivascular hemorrhages and changes in the ganglion cells compatible with the general cerebral edema. Finally, there was a small recent infarction in the cortex of the right kidney. Portions of liver, brain, kidney, pericardiac fluid, gastric contents, blood, heart, urine, and bile were examined for fluoride by the sodium silicofluoride test. The bile alone contained detectable amounts—0.02 mg. per 100 cc. by the zirconium-alizarin red test. The final anatomic diagnosis made was poisoning with sodium fluoroacetate; bronchopneumonia, with hemolytic septicemia due to a pyogenes var. aureus organism; focal infarction of right kidney; and mediastinal emphysema.

COMMENT

Since there is no known antidote to sodium fluoroacetate, therapy must be directed toward prevention of (1) serious cardiac arrhythmias, (2) central nervous system irritability, (3) peripheral vascular collapse, and (4) the general complications encountered in any patient who is comatose. In our recent experience with this disease entity, we have found certain agents that proved to be of definite, though short-lived, benefit to the patient. Myocardial irritability responded, at least temporarily, in a rather striking manner to the use of intravenously given procainamide hydrochloride, which completely abolished the premature ventricular contractions. Clinically, there was a distinct improvement in the quality of the heart sounds during and after the use of this drug. Several writers have agreed that procaine hydrochloride should be given by the intracardiac route in the case of ventricular fibrillation, known to be one of the immediate causes of death in human beings subjected to the poison. The ectopic beats, presumably the first signs of myocardial irritability, which might have progressed to more serious arrhythmias, such as ventricular tachycardia and ventricular fibrillation, were controlled by the use of procainamide hydrochloride. We feel that the possibility of death by ventricular fibrillation was prevented by use of this drug. The use of a digitalis preparation in the face of what was known to be a "toxic myocarditis" might give rise to some discussion. We had hoped to avoid the use of this substance, but our hand was forced by the intervention of acute pulmonary edema representing the most serious threat to life at the time it occurred. Short-acting lanatoside C was used because it was felt that this would relieve the pulmonary edema, which it did, without producing a cumulative cardiotoxic effect. There seemed to be no ill effects on cardiac irritability produced by this agent.

Secondly, the central nervous system manifestations, carpopedal spasm and generalized muscular hyperirritability, had to be dealt with. The barbiturates, calcium gluconate and magnesium sulfate, seemed to provide transient alleviation of these manifestations. With the institution of intravenous therapy with alcohol, these signs disappeared entirely and rather remarkably. It would seem likely, therefore, that this agent might, along with procainamide hydrochloride, be valuable in the therapy of this condition. In the third place, it was necessary to attempt to prevent death due to peripheral vascular collapse. In order to combat shock and to maintain an adequate renal blood flow, we used the vasodepressor drug mephentermine sulfate. We were thus able to maintain the patient's blood pressure above 100 mm. Hg systolic for a good part of the time and a good urinary output throughout the patient's hospital course. Finally, as in all cases of coma, alert nursing care was essential. Constant turning, frequent suctioning of the nasopharyngeal and even the tracheal and bronchial passages, use of alcohol sponges for fever, and nearly constant checking of the patient's vital signs were some of the more important of the many duties falling under the term nursing care.

In this case of fluoroacetate poisoning we considered, also, the use of agents recommended in the literature, such as magnesium sulfate in doses of 50 mg. per kilogram. This is known to prevent death in rats if given intramuscularly before or immediately after the ingestion of the poison. We also considered the use of monoacetin, which provides acetate and, thereby, theoretically produces its beneficial effect by this mechanism. We were advised by personal communication[8] that these agents were usually helpful only immediately after the intake of the poison; therefore, we relied on the therapy outlined herein and used much smaller doses of magnesium sulfate. Monoacetin was not available to us. It has also been suggested that chlorpromazine might be useful in that it provides an "artificial hibernation," which reduces central nervous system and cardiac irritability, as well as lowers the temperature.

---

[8] Fairhall, L.: Personal communication to the authors.

SUMMARY

Certain drugs can be used with benefit in a case of sodium fluoroacetate poisoning. These are (1) procainamide (Pronestyl) hydrochloride for cardiac arrythmias, (2) intravenously used alcohol for central nervous system irritability, and (3) vasodepressor drugs such as mephentermine (Wyamine) sulfate to maintain blood pressure. In the future these drugs, which we feel prolonged the life of our patient, should be tried in cases of sodium fluoroacetate poisoning, as they may save the lives of patients who have ingested smaller amounts of the poison.

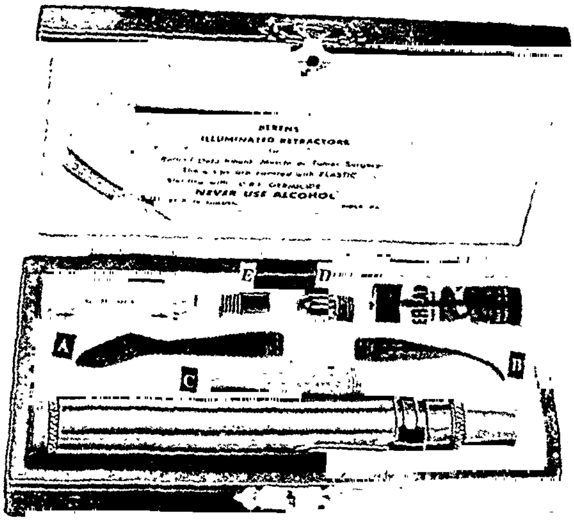
TRANSILLUMINATORS AND ILLUMINATED RETRACTORS FOR RETINAL DETACHMENT AND SURGERY

Conrad Berens, M.D., New York

The need for a compact and practical source of illumination for certain eye operations and for diagnosis instigated the development of a set of plastic retractors and transilluminators. These devices have been found to be useful and practical for retraction illumination, focal illumination, and transillumination of the eyeball.

A set of five tips, a sturdy flashlight handle, batteries, and an extra light bulb are encased in a compact leather case (see figure). The flashlight handle is made in two sizes. The small handle accommodates the no. 912 Eveready batteries, and the larger handle accommodates the regular no. 915 Eveready batteries, as well as the new long-life mercury batteries. The handles are machined from aluminium and are clear anodized, to prevent tarnishing. They contain no springs nor switches to wear out and are controlled by turning the base of the small flashlight and the base or top of the larger one. The three metal parts of the flashlight may be boiled or sterilized in alcohol and the inexpensive standard bulb and batteries inserted after sterilization. Three of the plastic light tips have a metallic mirror coating and are covered with plastic lacquer, allowing light to emerge only at the light-emitting surface.

The illuminated retractor (figure, *A*) is a modification of a retractor previously described [1] and has proved invaluable in operations on the retina and the inferior oblique muscle,[2] in orbital operations, and especially in evisceration of the eyeball.[3] The curved plastic tip (figure, *B*) permits light to emerge from the tip of the inner surface of the curve and is useful for transillumination of the posterior part of the globe in cases where tumors are suspected and for locating posterior retinal tears. The plastic tip, which is bent at a right angle (figure, *C*), is especially useful in examining the eye and transilluminating teeth and has been recommended as an accessory for a pocket flashlight for physicians.[4] The focal illuminator (figure, *D*) provides oblique illumination for the eye and may also be used in the examination for Purkinje vascular images. A cobalt blue glass tip (figure, *E*) is used for examining a fluorescein-stained cornea. The plastic tips may be sterilized in C. R. I. germicide (methyldodecylbenzyltrimethyl ammonium chloride, 17.5%, and inert ingredients, by weight, 82.5%). Neither alcohol nor boiling water should be used for sterilization of the plastic parts.



Transilluminators and illuminated retractor for retinal detachment and muscle and tumor surgery. *A*, plastic retractor; *B*, transilluminator for posterior part of the eyeball; *C*, transilluminator for anterior part of the eyeball; *D*, focal illuminator; and *E*, cobalt blue glass illuminator.

The advantages of the flashlight include the sturdy construction with no springs or switch, which wear out, and the fact that the flashlight may be sterilized without harming the instrument. Standard bulbs and batteries are used and offer no problem in replacement. The various plastic tips provide excellent illumination for retinal and muscle and tumor surgery and focal illumination for examination. The plastic tips are easily changed and present no problem so far as breakage is concerned. The set of transilluminators and illuminated retractors, flashlight, batteries, and the cobalt glass tip are fitted into a compact leather case. The instrument is also available with a cord for use with a rheostat.

THE CHANGE FROM ANTIBIOTIC-RESISTANT TO ANTIBIOTIC-SENSITIVE TUBERCLE BACILLI

Albert R. Allen, M.D.
and
Elizabeth A. Roberg, B.S., Selah, Wash.

The emergence of tubercle bacilli that are resistant to any antibiotic is an adaptation occurring spontaneously as a result of selective mutation for survival.[1] This phenomenon occurs in the laboratory and seems to occur also in patients. Its occurrence is related to the size of the original organism population and the concentration of the drug or drugs, but there must be bacterial multiplication for this selective mutation to occur. Loss of resistance is reported in a few strains resistant to 10 mg. per cubic centimeter of streptomycin after many months (22 to 42), with 10 to 21 transplants, but organisms resistant to high concentrations of streptomycin, 100 mg. per cubic centimeter, maintain this resistant characteristic. Courmont and others[2] found coexistence of bacilli sensitive and resistant to streptomycin in sputum, and Canetti and Saenz,[3] along with Medlar and others,[4] found variance in streptomycin resistance of tubercle bacilli from different pulmonary lesions in the same disease. Johnson and others[5] found not only that tubercle bacilli from embalmed bodies would grow but that organisms isolated before death and after death from different organs within the body and, indeed, from different areas of the lung might have different sensitivities. Stern and Goldman[6] found this to be true in resected specimens and found no correlation between type of pathological lesion and the resistant organisms. Mitchell and others[7] reported the recovery of streptomycin-sensitive tubercle bacilli from a patient who had previously yielded highly resistant bacilli. Incze[8] reported the reversibility of isoniazid-resistance in 5 of 56 patients during a six months' period when other drugs were added to the treatment program. Thus, if the lesion with resistant organisms was resected, then any organisms recovered later might be sensitive, or, if a new antibiotic were added that would control the growth of these resistant strains, then sensitive organisms might predominate in later cultures.

Results of Sensitivity Studies with Streptomycin and Isoniazid

Resected, Case No.	Sensitivity Information		Therapy	Complications
	Streptomycin	Isoniazid		
1	SR * 5/26/52 SS 7/22/52	....	Isoniazid, 250 mg. daily, introduced on 4/11/52. Change in sensitivity following new drug	None; discharged

2	SS 1/29/53	IR 1/29/53 IS 6/19/53	None for 5 mo. None for 10 mo.	Still positive
3	....	IR 6/ 8/53 IS 9/22/53 IR 12/14/53	No change in drugs during entire time	Death

* SR, streptomycin resistant; SS, streptomycin sensitive; SPR, partially streptomycin resistant.
† IS, isoniazid sensitive; IR, isoniazid resistant; IPR, partially isoniazid resistant.

In 14 of our patients we have seen the change from resistant to sensitive organisms to streptomycin or isoniazid occurring separately or in both drugs. Studies of sensitivity to 100 mg. per cubic centimeter of streptomycin and 20 mg. per cubic centimeter of isoniazid are done. The table shows the effort to correlate these changes with the addition of a new antibiotic or resection of the diseased tissues on one side.

COMMENT

There is no correlation between the addition of a new antibiotic or resection. The frequent changes from resistance to sensitivity and back in a seesaw manner seen in some of these patients to both streptomycin and isoniazid makes the probability of mutations unlikely. Therefore, the sputum samples obtained were probably from different lesions within the lungs. A correlation of the end-results in these 14 patients was most informative. There were 11 resections, with three deaths occurring while sputum samples were still positive, two within 48 hours of operation and the other six months after resection. The bronchial sutures, at autopsy, were all loose due to tissue absorption or the sutures were spit out. In these 11 resections, six patients developed bronchopleural fistulas that could not be closed by revision thoracoplasty or muscle graft, and, when further resection was done on one patient, that bronchus also opened. In all of these patients with bronchopleural fistulas there were organisms resistant to both drugs.

Three patients have been treated medically, with one death to date, but in the other two patients tests are still positive and will probably continue so until their death. In only five patients have tests become negative; these persons have been discharged. All persons in this group had over one year of chemotherapy, and all but one were admitted before 1952. In patients with organisms resistant to one major antituberculous drug, conversion is slower than in those with organisms sensitive to both,[9] but in the latter conversion is not spontaneous.

CONCLUSIONS

Patients with tubercle bacilli resistant to both streptomycin and isoniazid do not have spontaneous conversion of sputum. When subjected to resection, these patients are poor operative risks and have a high incidence of complications (bronchopleural fistulas, positive cultures after operation, and death). The change in bacilli from antibiotic-resistant to antibiotic-sensitive is due to a "sampling process" and not to a mutation. By this we mean that the resistant and sensitive organisms probably come from different lesions in the lungs.

CHRONIC BRUCELLAR PYELONEPHRITIS SIMULATING TUBERCULOSIS

Robert S. Abernathy, M.D.
William E. Price, M.D.
and
Wesley W. Spink, M.D., Minneapolis

The response to infection with Brucella is characterized by the formation of granulomatous lesions, particularly in those organs comprising the reticuloendothelial system. While the majority of patients with brucellosis recover without residual effects, chronic localized infections may involve the bones, joints, bursae, meninges, endocardium, lungs, liver, spleen, epididymides, testes, and kidneys. Such infections mimic tuberculosis and often cannot be differentiated histologically from tuberculosis. The present report is concerned with a patient in whom both the clinical course and pathological findings of brucellosis closely simulated tuberculosis. In addition, the patient presented several unusual features of brucellar infection. Localization of the disease in the urinary tract is an infrequently reported complication, while caseation of the tissues is a rare phenomenon in human brucellosis.

REPORT OF A CASE

A 46-year-old man was in apparent excellent health until April, 1954, when persistent urinary frequency, nocturia, and dysuria developed. In June, 1954, during an episode of colic in the left flank, a stone was passed through the urethra. Thereafter intermittent pyuria and hematuria occurred. Fever, chills, malaise, and other constitutional symptoms were all denied. The medical history and family history contained no significant details.

Physical Examination and Laboratory Data.—On July 26, 1954, the patient was admitted to the urological service of the University of Minnesota Hospitals. The only physical abnormalities were a temperature of 99.2 F (37.3 C) and an indefinite mass palpated in the right flank. The hemoglobin level was 11.9 gm. per 100 cc. The white blood cell count was 12,250 per cubic millimeter; the differential included 84% polymorphonuclear neutrophils, 12% lymphocytes, 2% monocytes, 1% eosinophils, and 1% basophils. The erythrocyte sedimentation rate was 106 mm. per hour (Westergren). The blood urea nitrogen level was 61 mg. per 100 cc. A urinalysis showed 1+ proteinuria, with numerous erythrocytes and leukocytes in the sediment. A routine urine culture yielded coagulase-negative Micrococcus pyogenes and diphtheroids. No acid-fast bacilli were found in smears of the urinary sediment. An intradermal test with 1:100 dilution of old tuberculin was negative. X-ray films of the abdomen revealed an enlarged left kidney with multiple calcifications in the upper portion. Following intravenous pyelography, no dye excretion from the left kidney was seen, while moderate hydronephrosis was present on the right (fig. 1). An aortogram confirmed the enlargement of the left kidney and demonstrated decreased vascularity of the upper portion, no evidence of tumor being noted. Cystoscopic examination revealed a severe and diffuse granular cystitis, and biopsy of the mucosa demonstrated only chronic granulation tissue. Attempts at retrograde dye studies of the kidney were unsuccessful.

Therapy.—The findings of cystitis and bilateral renal disease with calcification strongly suggested tuberculosis. However, in view of the negative tuberculin test and the absence of acid-fast bacilli in the urinary sediment, a diagnosis of brucellosis was suspected. Brucella agglutinins were absent in the serum. Specimens of blood and urine were cultured specifically for Brucella. After 10 days' observation, during which time the patient had

---

From the Department of Medicine and Division of Urology, University of Minnesota Hospitals and Medical School.

received streptomycin and aminosalicylic acid, these cultures did not reveal any growth. A clinical diagnosis of tuberculosis appeared most probable and a nephrectomy of the left kidney was performed on Aug. 5, 1954. The kidney was massively enlarged, and tissue was extensively replaced by numerous caseous abscesses (fig. 2).

On the day following surgery, Brucella suis was isolated from a culture of urine that had been under observation for several days. Br. suis was also isolated on direct culture of the excised kidney. When the patient was requestioned, he stated that he had formerly been a farmer. He had been repeatedly exposed to cattle with Bang's disease and had drunk raw milk from herds known to be infected. The last known exposure, however, had been in 1944, 10 years previous to this illness.

Course.—Postoperatively the patient received streptomycin, tetracycline, and penicillin. The blood urea nitrogen level, which was 89 mg. per 100 cc. prior to surgery, rose slowly thereafter. On the third postoperative day, intestinal obstruction developed. Despite gastric suction, this progressed and necessitated a cecostomy on the fifth day. Thereafter renal insufficiency supervened rapidly. By the eighth postoperative day anuria developed and the blood urea nitrogen level rose to 199 mg. per 100 cc. On the ninth day hypotension appeared. Despite the use of phenylephrine (Neo-Synephrine) hydrochloride, ephedrine, and arterenol, irreversible shock developed, and the patient died. Autopsy was not permitted.

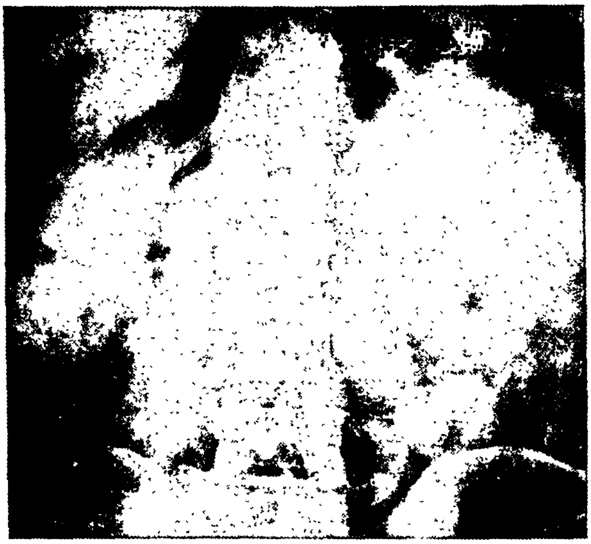

Fig. 1.—Intravenous pyelogram in patient with brucellar pyelonephritis. Note hydronephrosis of right kidney and absence of excretion from enlarged left kidney.

Further Laboratory Tests.—The removed kidney appeared typical of tuberculosis, both grossly and microscopically. Caseous material was found in several parenchymal abscesses and also in the pelvis. Yellowish nodules of various sizes were scattered throughout the cortex. Microscopic examination showed severe parenchymal destruction. Only a few areas of diluted tubules remained. The glomeruli were scant, and the majority were atrophic. A few glomeruli appeared normal. Throughout both cortex and medulla, there were numerous areas of mononuclear infiltration in which renal parenchyma was not discernible. In other sections, numerous granulomatous lesions with central caseation were found scattered throughout (fig. 3*A*). These lesions were composed of mononuclear cells at the periphery, epithelioid cells in the midzone, and caseation centrally (fig. 3*B*). Multinucleated giant cells were found both within these granulomas and at the periphery of the sheets of mononuclear infiltration. Within the more extensive and caseous lesions, eosinophilic cells were prominent. Careful searching of all sections revealed no acid-fast organisms. In sections stained with the Giemsa technique, cells containing multisized bodies with various staining reactions were prominent. With the use of special staining techniques, these cells were identified as mast cells.

Cultures directly from the excised kidney yielded no acid-fast organisms. A saline suspension of the kidney was injected into two guinea pigs. One animal died after three weeks. Autopsy of the animal revealed only a Pasteurella infection. No evidence of tuberculosis or brucellosis was found in the other animal, killed eight weeks after injection. The absence of Brucella agglutinins on routine testings of the patient's serum prompted further immunologic studies, which were done by Dr. Wendell Hall (fig. 4). The addition of the patient's serum in a dilution of 1:80 blocked the appearance of agglutination in a serum known to contain a high titer of agglutinins. In Coombs' test, the addition of globulin to the routine agglutination procedure caused agglutination in a 1:160 dilution of the serum. Centrifugation of the patient's serum with the standard tube Brucella antigen brought about agglutination at a 1:320 dilution. These results conclusively demonstrated the presence of blocking Brucella antibodies.

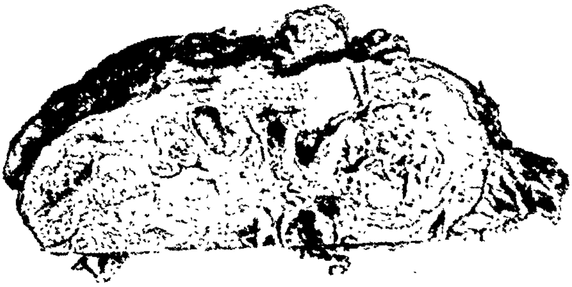

Fig. 2.—Left kidney after formaldehyde solution N. F. (Formalin) fixation. Note extensive caseous abscesses.

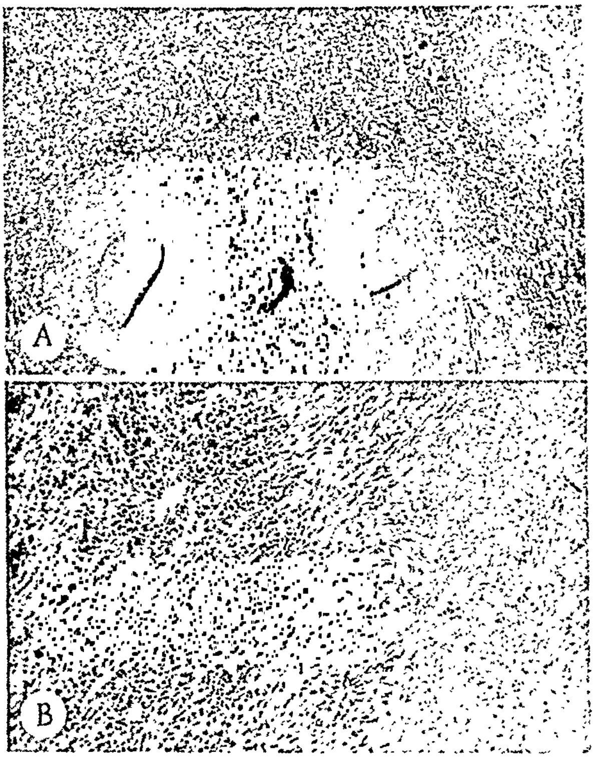

Fig. 3.—Photomicrographs of left kidney. *A*, extensive granulomatous infiltration and numerous tubercles. *B*, at the edge of a caseous lesion. Note mononuclear cells, epithelioid cells, and central caseation.

COMMENT

The resemblance to renal tuberculosis in this patient with proved brucellar pyelonephritis is remarkable. That the features of caseation, calcification, hydronephrosis, and secondary cystitis, all pathognomonic of renal tuberculosis, may also occur in brucellosis is not widely appreciated. Indeed, few reports of brucellosis involving the urinary tract have been recorded. This paucity in all probability reflects a low index of suspicion of brucellosis rather than the true incidence of urinary tract involvement. Support for this statement stems from data reported in 1905 by Kennedy[1] of the British Mediterranean Fever Commission. Fifty-four per cent of the patients with brucellosis from Br. melitensis had positive urine cultures. In some instances, Brucella organisms were successively cultured from urine for many months. These impressive data would indicate that brucellosis localized in the urinary tract may occur more frequently. Such an infection was not reported, however, until 1936, when Hardy and associates,[2] in a review of human brucellosis in Iowa, cited instances of cystitis and pyelonephritis that were initially thought to be tuberculous in origin but that on culture proved to be due to infection with Brucella. In 1939, Clark[3] reported a large series of patients with presumed brucellosis of the urinary tract. His reports unfortunately lack corroborative cultural or serologic data. In 1952, Weed and associates[4] presented a summary of a case similar to the present report. Excision of a 2 cm. mass from the right kidney of this patient revealed tissue having a calcific and caseous granulomatous appearance. Br. suis was cultured from this mass. In that same year, Greene and others[5] reviewed the literature concerning brucellar pyelonephritis and added two cases of patients with cystitis and calcific pyelonephritis, one due to Br. melitensis and the other to Br. suis. Two similar cases, in which the patients were both infected with Br. abortus, were reported in 1954 by Bickel[6] in Switzerland. In addition to these instances of pyelonephritis, references to nephritis in brucellosis are also found in the continental literature.[7]

TECHNIQUE	CONTROL AGGLUTINATION	AGGLUTINATION IN SERUM DILUTIONS 1:20	1:40	1:80	1:160	1:320	1:640

Centrifugation	0	1+	4+	4+	1+	1+	0

Fig. 4.—Results of special serum agglutination procedures.

These reports all emphasize that brucellar pyelonephritis is clinically and histologically indistinguishable from renal tuberculosis. It appears quite likely, therefore, that cases of presumed tuberculosis of the urinary tract in which acid-fast organisms are absent might well be brucellosis. Weed and associates,[8] by careful cultural studies of surgically excised tissues, have conclusively demonstrated the importance of Brucella organisms in the etiology of many chronic granulomatous infections, not only of the urinary tract but also of bones, joints, bursae, lungs, lymph nodes, prostate, epididymides, and fallopian tubes. They found that in such lesions, despite a histological diagnosis of tuberculosis, acid-fast bacilli could be cultured in only 55%; the remainder of these lesions were caused by Brucella, the various fungi, or Salmonella typhosa. These studies clearly show the necessity for precise bacteriology in establishing the correct etiology.

A precise bacteriological etiology is also of prime importance in selecting the proper therapy. The four patients with brucellar pyelonephritis and cystitis reported since the advent of antibiotics all responded promptly to specific antibiotic therapy. The patient in the case recorded here, however, had such severe destruction of the kidney that excision was indicated. Other unusual features in this patient include the presence of blocking antibiotics and caseation. Absence of Brucella agglutinins in the serum in culturally proved brucellosis has not occurred in our experience, although we have studied another patient with blocking antibodies. Hall and Manion[9] have discussed this phenomenon in detail. Weed and associates[4] report negative agglutination reactions in three of their patients with localized brucellar infections; however, no tests for the blocking phenomenon were reported. Caseation in human brucellosis is rare. Weed and associates[4] described five patients with caseous necrosis, similar to that seen in tuberculosis. An example of frank caseation of a lymph node due to Br. suis is reported by Crow and others.[10] These authors also stress that the granulomatous reaction, with or without caseation, is not a specific reaction to Mycobacterium tuberculosis but may occur in brucellosis, syphilis, tularemia, malignancies, the mycoses, sarcoidosis, and lipid pneumonia.

It is quite apparent that a chronic localized granulomatous infection is not necessarily tuberculous, as is often assumed. Careful bacteriological study must be done to determine the specific etiological agent. The foregoing case report again emphasizes that, in the search for the etiological agent, the index of suspicion for brucellosis should be high.

SUMMARY

In a case of chronic caseous calcific pyelonephritis with cystitis caused by Brucella suis, histopathological studies of an excised kidney revealed an extensive granulomatous reaction, indistinguishable from tuberculosis.

Blocking Brucella antibodies were present in the serum. Since histopathological study cannot distinguish between tuberculosis, brucellosis, the mycoses, or typhoid fever, precise cultural studies of chronic localized granulomatous lesions are necessary. The case reported here and other examples from the literature emphasize the importance of a high index of suspicion for brucellosis in such lesions.

ADDENDUM

A recent review of Brucella infections of the genitourinary tract has appeared since this manuscript was submitted for publication.[11]

COUNCIL ON PHARMACY AND CHEMISTRY

Report to the Council

The Council on Pharmacy and Chemistry has authorized publication of the following report.

H. D. Kautz, M.D., *Secretary.*

The persistently large number of accidental poisonings that are reported annually has focused medical attention on the causes and possible remedies for this situation, especially as it relates to children. It is generally agreed that the curiosity of children coupled with the casualness with which many parents handle and store drugs and chemicals are predisposing factors to most unintentional poisonings. Unhappily, agreement has not been obtained in all quarters on corrective measures. The following report has been adopted by the Committee on Toxicology as expressing its attitude on this perennial problem.

Bernard E. Conley, *Secretary*
Committee on Toxicology.

THE PROBLEM OF ACCIDENTAL POISONING IN CHILDREN AS IT EXISTS TODAY

Jay M. Arena, M.D., Durham, N. C.

Of approximately 14,000 accidental deaths that occur each year in children from 1 to 14 years of age, almost 1,500 are reported as being caused by the accidental ingestion of a poison, but this figure is far from correct. Each year many infants and small children die from poisoning, and the correct diagnosis is never made nor tabulated on a death certificate or statistical chart. As many of the present toxic agents affect the central nervous system, causing convulsions, the diagnosis is often classified as encephalitis if there is no history of ingestion of toxic substances. This erroneous diagnosis is being made in the best of hospitals.

The alarming feature of this problem, however, is the regularity with which various household agents and drugs are ingested by children. Every day many physicians receive an emergency call from a frantic mother stating that her child has ingested some poisonous substance. This is understandable, however, when one realizes what the usual household contains today as compared to the agents children had to be wary of 20 to 30 years ago. We now have deodorants, depilatories, detergents, herbicides, insecticides, rodenticides, stimulants, sedatives, analgesics, and so forth.

An analysis of 502 cases of accidental poisoning in children under the age of 12 years, seen at the Royal Hospital for Sick Children, Edinburgh, Scotland, showed that a tenfold increase in such cases occurred between 1931 and 1951.[1] In 1931 there were 5 cases annually; in 1951 there were more than 50. The causative agents were classified as follows: group 1, household substances, such as disinfectants, fuels, cleaning agents, and insecticides, 203; group 2, medicines, including those intended for internal use, such as camphor, barbiturates, iron, and salicylates, 185, and those intended for external use, such as liniments and nose and eye drops, 75; group 3, vegetable matter, such as seeds and berries, 35; and group 4, source unidentified, 4. Throughout the period covered by the investigation, the number of cases caused by household substances increased steadily, but after 1948 the number caused by drugs rose sharply because of increased prescribing under the National Health Service. More than half the cases (331) occurred in children between the ages of 1 and 3 years and only 38 in children over 5 years of age.

Dr. Katherine Bain [2] of the United States Children's Bureau has recently shown that the number of deaths from ingestion of poisons in children under 5 years of age is four times higher in the United States than in Britain. Inasmuch as most of the death rates in the United States and Great Britain are generally comparable, it was felt such a great difference in the specific rate by accidental poisoning should be carefully analyzed and publicized to encourage attempts to determine the cause and promote preventive measures (see figure).

Foodstuffs are no longer a common source of poisoning. Only eight deaths resulted from this cause in the two years under investigation, and these were attributed to such substances as wild berries, toad stools, and green pecans. Slightly less than a third of the deaths were caused by drugs or medicaments. A little more than a third were caused by general household items such as bleaching agents, furniture polish, and moth balls. A quarter were caused by petroleum products, principally kerosene. Five per cent of the deaths resulting from poisoning in the home were unclassifiable because of insufficient data on the death certificates.

Some of the drug poisoning in small children is a result of overdosing, but a great deal of it is like any other household poisoning—the child simply swallows something he has found. The most common drug offender in

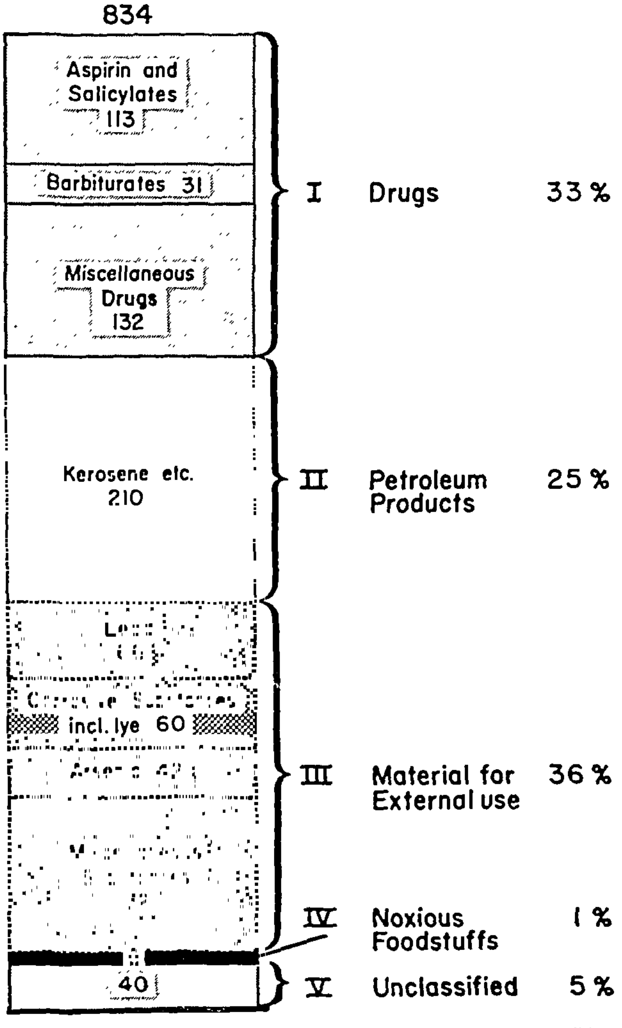
this age group is aspirin, as evidenced by previous Committee on Toxicology reports on this subject.[3] The flavoring of aspirin tablets for children has been associated with an alarming increase in the incidence of accidental poisoning. The flavoring has improved the taste and palatability to the extent that some children will go out of their way to search for it just as they may do for candy.

The American people spend a great deal of money on drugs. In 1951 the public spent about three-fourths of a billion dollars on prescriptions and a full billion dollars on packaged medicaments, of which $135 million went for aspirin and analgesics. This widespread distribution suggests that practically every household has such medicaments available. Too frequently adults assume that these drugs are harmless and leave them where young children can easily reach them.



Substances responsible for death from accidental poisoning of children under 5 years of age: United States, 1949 and 1950.

Childhood deaths from poisoning occur disproportionately often in 12 southern states—Alabama, Arkansas, Florida, Georgia, Louisiana, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, and Virginia. The rate for these states as a group is 4.09 per 100,000 population as against 2.00 for the remainder of the country. For the barbiturates and aspirin there is little regional difference, but for corrosives and arsenic the rate for these southern states is six times that for the rest of the country and the rate for petroleum products (principally kerosene) is four times as high.

SOLUTION TO THE PROBLEM

The solution to this problem is manifold and complex. There are at least four methods that hold promise and should be investigated and employed wherever applicable: (1) education, (2) more stringent laws, (3) the establishment of poison centers, and (4) greater effort by physicians on the local level.

Education.—Quite apparent to everyone is the need for educating laymen and parents to the dangers that household agents may present; however, many physicians are unaware of these dangers, and they also must be educated. Manufacturers of these products must be made aware of the seriousness of the problem and their responsibilities. They should contemplate the use of distinctive safety containers, better labeling with precautionary statements, and, when indicated, uniformly standardized doses of drugs. For example, the use of a standard strength of 1.25 grains (75 mg.) for children's aspirin tablets would be a great step forward in diminishing the incidence of aspirin poisoning.

More Stringent Federal and State Laws.—The Federal Caustic Poison Act enforced by the Food and Drug Administration requires that the word "Poison" and an acceptable antidote be placed prominently on the label of a household package of a preparation that contains more than a specified amount of any one of 12 specific caustics or corrosives. The Federal Food, Drug and Cosmetic Act, also enforced by the Food and Drug Administration, does not require the use of the poison legend on any drug preparation.

The Federal Insecticide, Fungicide, and Rodenticide Act of 1947, enforced by the Department of Agriculture, requires that certain white economic poisons be colored and requires that the labels of economic poisons toxic to man bear the skull and crossbones and the word "Poison" prominently in red on a background of contrasting color with a statement of the antidote. These Federal Acts are useful as far as they go; however, they are far from adequate.

On April 14, 1954, the Department of Health, Education and Welfare (Food and Drug Administration) sent out the following memorandum: "To minimize accidental poisonings by oil of wintergreen preparations (methyl salicylate), products containing more than 5% of this ingredient will be considered as misbranded unless their labels warn that use contrary to directions may be dangerous and that the article should be kept out of reach of children to prevent accidental poisoning."

This is a step in the right direction. Other preparations such as camphorated oil (containing 20% camphor) should also be included and so labeled. Legislation should be considered to provide regulation of the sale of household articles not now covered by existing statutes to remove the risk from accidental ingestion and misuse of such preparations, especially by children, and to provide informative labeling. In the absence of federal legislation to safeguard distribution of household articles, such as kerosene and other petroleum distillates that are serious offenders, consideration could be given to enactment of such legislation so as to protect the public. In addition, physicians and lay groups should work for appropriate state laws to strengthen the federal laws and to bring about correction of their special problems as found within a state. In this connection, consideration could be given to a law restricting the sale of kerosene other than in a special container, which would prohibit the use of any other type of container. In addition, such containers should bear informative warnings as to the poisonous and combustible properties of kerosene and like substances. A suggested caution label is as follows:

Candy Medication and Accidental Poisoning, report of Committee on Toxicology to the Council on Pharmacy and Chemistry, ibid. 158:44 (May 7) 1955.

> WARNING
>
> Kerosene is inflammable and may produce dangerous explosions.
>
> If it is swallowed, it may cause fatal damage to the lungs. It should be kept out of the reach of children and should never be put in beverage bottles, glasses, or cups or left in unlabeled containers.

Poison Centers.—Another approach to the problem would be the establishment of a network of poisoning control centers throughout the country. The pattern for these centers could be similar to that developed in Chicago by a committee of the Illinois Academy of Pediatrics with Dr. Edward Press as chairman. The organization and functioning of these centers would vary in accordance with the individual situation and facilities in each of the cities. It would be hoped, however, that the information pertaining to the type, incidence, treatment, and preventive measures for such poisoning developed in each center could be correlated and made available to all other centers and to all other persons throughout the country involved in a sound program of prevention and treatment of poisoning.

Cooperation of Physicians.—Another step forward would be a concentrated effort by every physician on the local level to educate parents to the hazards of poisons and other dangerous substances found in and about the home. This can be done by pointing out corrective measures while making home calls, by passing out and insisting that mothers read child safety booklets, and by using a bulletin board in the office to highlight accidents and poisonings that occur in the community each week. It is also advisable to obtain wider public health education through encouragement of community programs to study the local problems of poisonings and to make available such information through public service mediums such as newspapers, magazines, radio, films, speeches, and displays. Lastly, much can be accomplished by getting the cooperation of the pharmacists in putting a label such as "Keep out of the hands of children" on all dangerous drugs and agents.

NEW AND NONOFFICIAL REMEDIES

Monographs and supplemental statements on drugs that appear in this column have been authorized by the Council for publication and inclusion in New and Nonofficial Remedies. They are based upon the evaluation of available scientific data and reports of investigations.

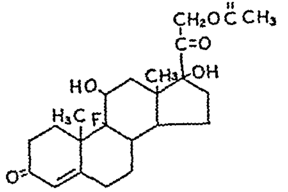
Fludrocortisone Acetate. — $C_{23}H_{31}FO_6$. — M.W. 422.50. — 9α-fluoro-17-hydroxycorticosterone-21-acetate.—The structural formula of fludrocortisone acetate may be represented as follows:



Actions and Uses.—Fludrocortisone acetate, a derivative of hydrocortisone acetate, has the same qualitative actions. It usually appears to be effective in smaller doses than required with hydrocortisone and shares with hydrocortisone the same relative freedom from untoward local effects. Thus, at its effective dosage level of anti-inflammatory action, fludrocortisone can be considered to have the same ratio of therapeutic to untoward effects as hydrocortisone.

Fludrocortisone acetate is effective topically for the local management of allergic dermatoses, such as contact dermatitis and atopic dermatitis (including allergic eczema, disseminated neurodermatitis, and eczematoid dermatitis), seborrheic dermatitis, pruritus with lichenification, and nonspecific anogenital pruritus. Although systemic effects following the topical application of fludrocortisone are very rare, retention of sodium and subsequent edema may occur. Local irritation and sensitivity reactions have not been attributed to its topical use, but patients should be observed carefully for such reactions, particularly with respect to the nonactive components of the vehicle employed.

The systemic usefulness of fludrocortisone is under clinical investigation and has not yet been established.

Dosage.—A concentration of 0.05 to 0.25% fludrocortisone acetate is administered topically in a suitable dermatological ointment or lotion. A small quantity of either ointment or lotion is applied to the involved area two to four times daily. Unduly vigorous massage that may damage the skin should be avoided. Careful cleansing prior to application is essential to minimize the possibility of introducing infection.

Sharp & Dohme, Division of Merck & Co., Inc., and E. R. Squibb & Sons, Division of Olin Mathieson Chemical Corporation, cooperated by furnishing scientific data to aid in the evaluation of fludrocortisone acetate.

REHABILITATION

Rehabilitation may be defined as the process of assisting the handicapped person to realize his potentialities and goals physically, mentally, socially, and economically.[1] The growing need for rehabilitative facilities is the direct result of the enormous increase in traumatic injuries and the increase in chronic degenerative diseases in our aging population. It is estimated that at least 2 million persons in the United States have disabilities requiring vocational rehabilitative services.[2] This does not include persons with minor disabilities, older persons, and other groups who could benefit from rehabilitation. Although most authorities believe that rehabilitative facilities should be developed in large hospital centers, Cambridge, Mass., solved its problem not by organizing a center but by employing a rehabilitation coordinator to guide patients to and assure better use of existing local and state facilities.[3] This procedure assumes the availability of adequate facilities. Although a number of the smaller hospitals that cannot provide a comprehensive integrated rehabilitative service have used this approach with some success, it does not solve the problem of the separate services required by severely disabled persons. Where rehabilitation centers have been established, they find it necessary to provide physiatrists; physical therapists; occupational therapists; speech and hearing therapists; clinical psychologists; nurses; a prosthetic service; vocational evaluation, counselling, and training service; social service; and a therapeutic recreation service.

The greatest need of many patients is motivation, and this is greatly aided by convincing the patient that he can regain or compensate for much of his lost power. This must be done early in the course of his treatment before he becomes unduly discouraged or develops an attitude of dependency. According to Rusk[4] the aim of rehabilitation is to train the patient to live within the limits of his disability but to the hilt of his capacity. That capacity often surprises the patient, the doctor, and all beholders. Rehabilitative measures are particulary applicable to patients with poliomyelitis, spinal cord injury, cerebral palsy, various forms of arthritis, speech disorders, amputations, and cerebral vascular accidents.[5] Hospitalized patients who receive the benefit of rehabilitative measures recover more promptly and thus reduce their stay in the hospital. Furthermore, it has been shown that the readmission rate for such patients is lower than that for those who do not have this type of treatment, and even those whose condition is such that they will require prolonged hospitalization can be helped to a degree of self-care that will greatly reduce the nursing burden.[6] Since few persons want to be a burden on others, this not only helps the hospital staff but greatly improves the morale of the patient.

The suddenly disabled patient may be difficult to treat. Resentful of his disability, he may vent his resentment on those nearest him who are trying to help him. The physician and therapist must understand this resentment and not take it as a personal affront, for to do so would make effective therapy almost impossible.[7] Those who treat these patients must also guard against a feeling of hostility toward those patients for whom they can do relatively little. Although it is frustrating to treat a patient and not see any progress day after day, a feeling of resentment toward the patient will vitiate the only hope the patient has of achieving some fraction of his former independence. The bright side of the picture is the achievement of rehabilitation where treatment has been vigorously applied. In 1954, under the National Vocational Rehabilitation Program about 60,000 persons were returned to employment, and under the greatly expanded Federal-State Vocational Rehabilitation Program there is an objective of 200,000 persons rehabilitated annually by 1959. It has been shown that the accident rate in disabled employees is lower than that in their fellow workers; disabled workers maintain a better production record and have less absenteeism; and, often, due to the loss of a limb or a sense, a much greater than average skill in other limbs or senses is developed as a compensatory measure—this sharpened skill adds to the employee's value to his employer.

Physical and mental inactivity are not good for anyone. People who have made fun of basket weaving should realize that occupational therapy has come a long way since basket weaving was its mainstay, but they should also realize that the chief value of even such measures as basket weaving is to give the patient confidence in his ability to perform manual tasks.[8] Although rehabilitation is admittedly expensive, it has been shown to pay dividends far exceeding its cost. The need for more facilities is urgent, and the chief reason that they are not being developed more rapidly is that many persons responsible for the care and support of the chronically disabled have only a vague idea of what rehabilitative services can do.[2]

SPONTANEOUS RUPTURE OF THE ESOPHAGUS

Spontaneous rupture of normal esophagus is a rare occurrence. The celebrated Dutch clinician Boerhaave gave the first and remarkably accurate description of it in 1724. The patient was "the illustrious Baron Wassenaer, Lord High Admiral to the Republick, [who] after intense straining and vomiting broke asunder the tube of the esophagus, near the diaphragm, so that after the most excruciating pains the aliments which he swallowed passed, together with the air, into the cavity of the thorax, and he expired in 24 hours." [1]

Walker [2] in 1914 reported one case, the first of the four reported in literature in which diagnosis was made before death. He was able to find only 22 cases of spontaneous rupture of the esophagus reported in the literature. Ridgway and Duncan [3] in 1937 culled 35 cases from literature. Eliason and Welty [4] described in 1946 three cases in which the diagnosis was made post mortem. They stated that the mortality in spontaneous rupture of the esophagus so far reported was 100% and that most patients succumbed within 24 hours.

Kinsella [5] stresses that the clinical picture of spontaneous rupture of the esophagus is not generally recognized despite the fact that its symptoms are quite characteristic. Rupture of the esophagus usually occurs during an episode of vomiting, often preceded by a bout of drinking or a heavy meal. The pain radiates to the back or to the interscapular region; it is most excruciating and is not relieved by morphine. There develop collapse, shock, dyspnea, and cyanosis. In 60 to 70% of the cases there appears emphysema of the tissues at the base of the neck. There is frequently rigidity of the upper part of the abdomen. As the case progresses signs of hydropneumothorax may be elicited, with fluid level on one or both sides, more frequently on the left. There may be evident displacement of the heart and mediastinal structures. Mackler [6] considers the triad of vomiting, low thoracic pain, and emphysema of the neck as diagnostic of the condition. The presence of gastric contents in aspirated pleural fluid is pathognomonic. Iodized oil (Lipiodol) swallow may also confirm the diagnosis. X-ray examination is of the greatest value. The films may reveal emphysema of the mediastinum, a fluid level in the mediastinum, or a pneumothorax. The lesion most frequently suspected is perforated peptic ulcer. Other conditions to be ruled out in the differential diagnosis are acute coronary occlusion, acute pancreatitis, spontaneous pneumothorax, dissecting aneurysm of the aorta, and pulmonary embolism.

The question of why the normal esophagus ruptures has not been definitely elucidated. Most observers feel that the important factor is a great increase of pressure within it. A sudden increase is probably more important than the total degree of pressure. The esophagus ruptures at its lower end, 1 or 2 in. above the diaphragm. This appears to be its weakest portion, as demonstrated in experiments by Weiss and Mallory [7] and by Mackler.[6] Mackler inflated the esophagus in 65 fresh human cadavers. The rupture occurred in all instances at the lower extremity of the organ upon its left lateral wall. The site and configuration of the resulting rupture duplicated the clinical lesion.

Barrett [8] of London reported in 1947 the first case in which operation was successfully done in spontaneous perforation of the esophagus. Olsen and Clagett [9] likewise reported in 1947 an instance of spontaneous rupture of the esophagus immediately diagnosed and successfully operated on by transthoracic repair of the torn esophagus. Samson [10] reported two cases of postemetic rupture of the esophagus in which the diagnosis was made early, the resuscitation was intensive, and thoracotomy with direct repair of the esophageal tear resulted in prompt recovery. He emphasizes that the signs and symptoms of rupture of the esophagus are practically pathognomonic and not difficult to recognize if the lesion is kept in mind. The essentials of treatment consist of rapid resuscitation, thoracotomy with definitive repair of the esophageal tear, and drainage of the mediastinum. It is reasonable to believe that with early diagnosis and early repair of the rupture, aided by antibiotics and supportive measures, the mortality rate from this hitherto catastrophic event will be greatly decreased.

LYE POISONING

A report to the Committee on Toxicology in this issue (page 1537) points out that the rate for fatal poisoning in children by certain nonmedical chemicals in the South is several times that for the rest of the country. Lye and kerosene poisoning are among the most common causes of injury in this age group.

In a recent discussion of this sectional problem before the Committee on Toxicology, it was pointed out that in one southern state about 150 cases of lye poisoning occur each year, with six to eight deaths annually. Eighty-five per cent of the cases occur among poor and illiterate persons who use lye because of its inexpensiveness and potency as a cleanser. It was further suggested that use in the home would be discouraged if the sale of lye in small containers were banned. While it is generally recognized that decreasing access to a poison reduces the frequency of injury, no general agreement has been obtained on this prohibition. Agitation to explore the legal aspects of this proposal has obtained support in areas where the problem of lye poisoning is most acute.

REHABILITATION

Rehabilitation may be defined as the process of assisting the handicapped person to realize his potentialities and goals physically, mentally, socially, and economically.[1] The growing need for rehabilitative facilities is the direct result of the enormous increase in traumatic injuries and the increase in chronic degenerative diseases in our aging population. It is estimated that at least 2 million persons in the United States have disabilities requiring vocational rehabilitative services.[2] This does not include persons with minor disabilities, older persons, and other groups who could benefit from rehabilitation. Although most authorities believe that rehabilitative facilities should be developed in large hospital centers, Cambridge, Mass., solved its problem not by organizing a center but by employing a rehabilitation coordinator to guide patients to and assure better use of existing local and state facilities.[3] This procedure assumes the availability of adequate facilities. Although a number of the smaller hospitals that cannot provide a comprehensive integrated rehabilitative service have used this approach with some success, it does not solve the problem of the separate services required by severely disabled persons. Where rehabilitation centers have been established, they find it necessary to provide physiatrists; physical therapists; occupational therapists; speech and hearing therapists; clinical psychologists; nurses; a prosthetic service; vocational evaluation, counselling, and training service; social service; and a therapeutic recreation service.

The greatest need of many patients is motivation, and this is greatly aided by convincing the patient that he can regain or compensate for much of his lost power. This must be done early in the course of his treatment before he becomes unduly discouraged or develops an attitude of dependency. According to Rusk[4] the aim of rehabilitation is to train the patient to live within the limits of his disability but to the hilt of his capacity. That capacity often surprises the patient, the doctor, and all beholders. Rehabilitative measures are particulary applicable to patients with poliomyelitis, spinal cord injury, cerebral palsy, various forms of arthritis, speech disorders, amputations, and cerebral vascular accidents.[5] Hospitalized patients who receive the benefit of rehabilitative measures recover more promptly and thus reduce their stay in the hospital. Furthermore, it has been shown that the readmission rate for such patients is lower than that for those who do not have this type of treatment, and even those whose condition is such that they will require prolonged hospitalization can be helped to a degree of self-care that will greatly reduce the nursing burden.[6] Since few persons want to be a burden on others, this not only helps the hospital staff but greatly improves the morale of the patient.

The suddenly disabled patient may be difficult to treat. Resentful of his disability, he may vent his resentment on those nearest him who are trying to help him. The physician and therapist must understand this resentment and not take it as a personal affront, for to do so would make effective therapy almost impossible.[7] Those who treat these patients must also guard against a feeling of hostility toward those patients for whom they can do relatively little. Although it is frustrating to treat a patient and not see any progress day after day, a feeling of resentment toward the patient will vitiate the only hope the patient has of achieving some fraction of his former independence. The bright side of the picture is the achievement of rehabilitation where treatment has been vigorously applied. In 1954, under the National Vocational Rehabilitation Program about 60,000 persons were returned to employment, and under the greatly expanded Federal-State Vocational Rehabilitation Program there is an objective of 200,000 persons rehabilitated annually by 1959. It has been shown that the accident rate in disabled employees is lower than that in their fellow workers; disabled workers maintain a better production record and have less absenteeism; and, often, due to the loss of a limb or a sense, a much greater than average skill in other limbs or senses is developed as a compensatory measure—this sharpened skill adds to the employee's value to his employer.

Physical and mental inactivity are not good for anyone. People who have made fun of basket weaving should realize that occupational therapy has come a long way since basket weaving was its mainstay, but they should also realize that the chief value of even such measures as basket weaving is to give the patient confidence in his ability to perform manual tasks.[8] Although rehabilitation is admittedly expensive, it has been shown to pay dividends far exceeding its cost. The need for more facilities is urgent, and the chief reason that they are not being developed more rapidly is that many persons responsible for the care and support of the chronically disabled have only a vague idea of what rehabilitative services can do.[2]

SPONTANEOUS RUPTURE OF THE ESOPHAGUS

Spontaneous rupture of normal esophagus is a rare occurrence. The celebrated Dutch clinician Boerhaave gave the first and remarkably accurate description of it in 1724. The patient was "the illustrious Baron Wassenaer, Lord High Admiral to the Republick, [who] after intense straining and vomiting broke asunder the tube of the esophagus, near the diaphragm, so that after the most excruciating pains the aliments which he swallowed passed, together with the air, into the cavity of the thorax, and he expired in 24 hours." [1]

Walker [2] in 1914 reported one case, the first of the four reported in literature in which diagnosis was made before death. He was able to find only 22 cases of spontaneous rupture of the esophagus reported in the literature. Ridgway and Duncan [3] in 1937 culled 35 cases from literature. Eliason and Welty [4] described in 1946 three cases in which the diagnosis was made post mortem. They stated that the mortality in spontaneous rupture of the esophagus so far reported was 100% and that most patients succumbed within 24 hours.

Kinsella [5] stresses that the clinical picture of spontaneous rupture of the esophagus is not generally recognized despite the fact that its symptoms are quite characteristic. Rupture of the esophagus usually occurs during an episode of vomiting, often preceded by a bout of drinking or a heavy meal. The pain radiates to the back or to the interscapular region; it is most excruciating and is not relieved by morphine. There develop collapse, shock, dyspnea, and cyanosis. In 60 to 70% of the cases there appears emphysema of the tissues at the base of the neck. There is frequently rigidity of the upper part of the abdomen. As the case progresses signs of hydropneumothorax may be elicited, with fluid level on one or both sides, more frequently on the left. There may be evident displacement of the heart and mediastinal structures. Mackler [6] considers the triad of vomiting, low thoracic pain, and emphysema of the neck as diagnostic of the condition. The presence of gastric contents in aspirated pleural fluid is pathognomonic. Iodized oil (Lipiodol) swallow may also confirm the diagnosis. X-ray examination is of the greatest value. The films may reveal emphysema of the mediastinum, a fluid level in the mediastinum, or a pneumothorax. The lesion most frequently suspected is perforated peptic ulcer. Other conditions to be ruled out in the differential diagnosis are acute coronary occlusion, acute pancreatitis, spontaneous pneumothorax, dissecting aneurysm of the aorta, and pulmonary embolism.

The question of why the normal esophagus ruptures has not been definitely elucidated. Most observers feel that the important factor is a great increase of pressure within it. A sudden increase is probably more important than the total degree of pressure. The esophagus ruptures at its lower end, 1 or 2 in. above the diaphragm. This appears to be its weakest portion, as demonstrated in experiments by Weiss and Mallory [7] and by Mackler.[6] Mackler inflated the esophagus in 65 fresh human cadavers. The rupture occurred in all instances at the lower extremity of the organ upon its left lateral wall. The site and configuration of the resulting rupture duplicated the clinical lesion.

Barrett [8] of London reported in 1947 the first case in which operation was successfully done in spontaneous perforation of the esophagus. Olsen and Clagett [9] likewise reported in 1947 an instance of spontaneous rupture of the esophagus immediately diagnosed and successfully operated on by transthoracic repair of the torn esophagus. Samson [10] reported two cases of postemetic rupture of the esophagus in which the diagnosis was made early, the resuscitation was intensive, and thoracotomy with direct repair of the esophageal tear resulted in prompt recovery. He emphasizes that the signs and symptoms of rupture of the esophagus are practically pathognomonic and not difficult to recognize if the lesion is kept in mind. The essentials of treatment consist of rapid resuscitation, thoracotomy with definitive repair of the esophageal tear, and drainage of the mediastinum. It is reasonable to believe that with early diagnosis and early repair of the rupture, aided by antibiotics and supportive measures, the mortality rate from this hitherto catastrophic event will be greatly decreased.

LYE POISONING

A report to the Committee on Toxicology in this issue (page 1537) points out that the rate for fatal poisoning in children by certain nonmedical chemicals in the South is several times that for the rest of the country. Lye and kerosene poisoning are among the most common causes of injury in this age group.

In a recent discussion of this sectional problem before the Committee on Toxicology, it was pointed out that in one southern state about 150 cases of lye poisoning occur each year, with six to eight deaths annually. Eighty-five per cent of the cases occur among poor and illiterate persons who use lye because of its inexpensiveness and potency as a cleanser. It was further suggested that use in the home would be discouraged if the sale of lye in small containers were banned. While it is generally recognized that decreasing access to a poison reduces the frequency of injury, no general agreement has been obtained on this prohibition. Agitation to explore the legal aspects of this proposal has obtained support in areas where the problem of lye poisoning is most acute.

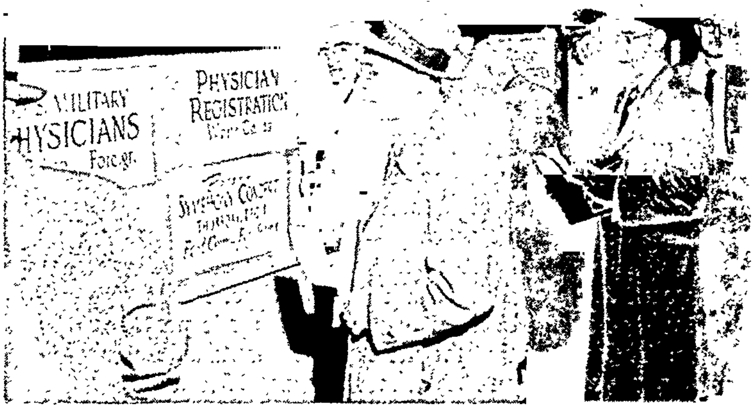
BOSTON MEETING

Right, hundreds of physicians registered in opening hours of the session in Mechanics Hall to view exhibits and attend discussions, motion pictures, and color television presentations.



Below, at Medical Public Relations Conference, Sen. Wallace F. Bennett of Utah gave an address on "Is Free Enterprise Here to Stay?" He was welcomed to the conference by A. M. A. President Elmer Hess (left).

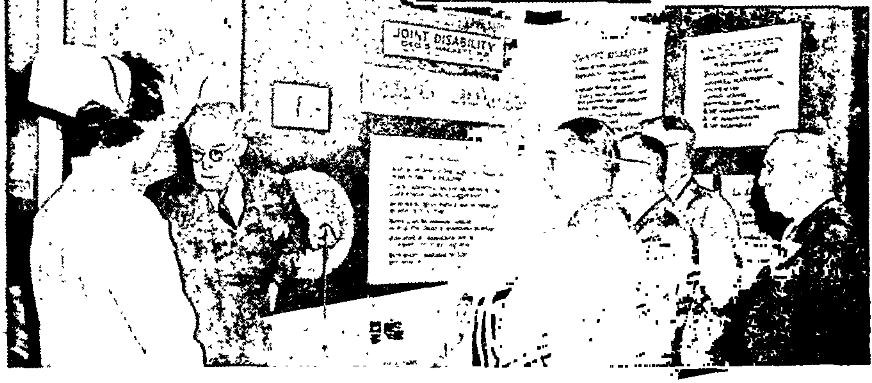
Below, Medical Society Executives Conference met for a New England shore dinner at the Harvard Club. Lester H. Perry (left), executive secretary, Pennsylvania Medical Society, and M. C. Smith, executive secretary, Nebraska State Medical Association, whet their appetites while appraising the lobsters. The dinner climaxed a full day's program at the Parker House.

Below, at Hawaiian booth in Mechanics Hall, Dr. William G. Richtmyer, Albany, N. Y., thought a trip to the centennial meeting of the Hawaiian Medical Association in Honolulu April 22-29 a good idea when told about it by B. J. Feldman (left) and Margaret Brumaghin, both of Hawaii Airlines, Honolulu.

Below, Boston vied for attention among visitors to the Clinical Meeting. Here, Dr. and Mrs. Fred Humphrey, Fort Collins, Colo., plan their sightseeing itinerary with the Statler tour agent.

Left, after the announcement of his selection as 1955 General Practitioner of the Year, Dr. E. Roger Samuel, Mount Carmel, Pa., was interviewed, photographed, and filmed by members of the press at a news conference.

One of the most popular special features of each meeting is the demonstration on fractures. Right, Drs. M. J. Giannestras, Cincinnati; Franklin V. Wade, Flint, Mich.; and William Lannigan, Boston (left to right), apply a traction device in the Scientific Exhibit.



Left, Dr. G. S. Hackett's demonstration of treatment of "low back pain" brought a large audience to his exhibit.

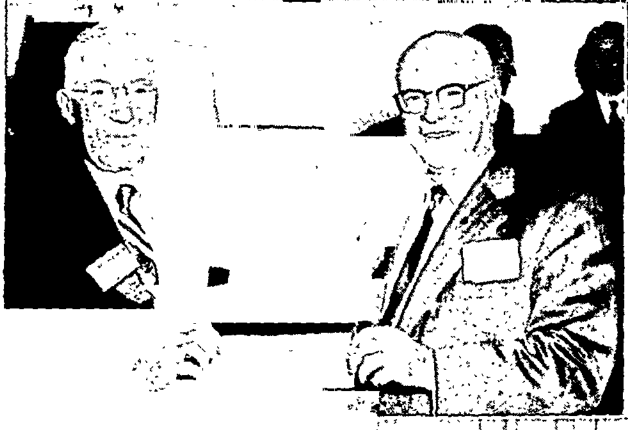
Below, push-button device in National Tuberculosis Association exhibit was one of the many interesting features.

Below, what is new in hydrotherapeutic tanks was demonstrated by Ralph E. Worden.

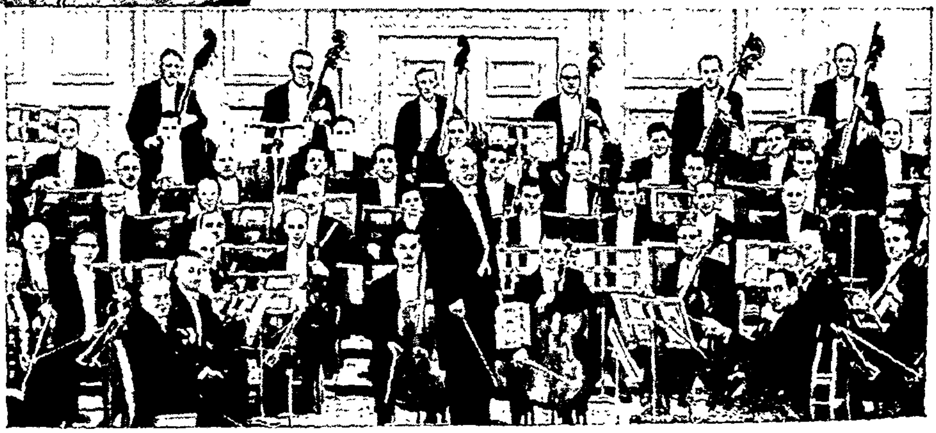
After reference committees discussed resolutions presented to the House of Delegates, their reports were heard by the House. In session here is the Reference Committee on Insurance and Medical Service.

V. C. Royster, senior associate editor of the Wall Street Journal, New York, spoke on "The Doctor's Future in America" at the eighth Medical Public Relations Conference.

Erle Cocke Jr. (left), vice president of Delta Airlines; Leonard E. Read, president, Foundation for Economic Education; and U. S. Congressman Thomas B. Curtis, Missouri, were guest speakers at the Medical Public *Relations Conference* and were *greeted by* A. M. A. President-Elect Dwight H. Murray (second from left).



Left, California Medical *Association* was the donor of a $25,000 check to the American Medical Education Foundation. Dr. Louis H. Bauer (left), president of the AMEF board of directors, accepted the gift from Dr. Donald Cass of the California delegation.



Dr. Charles Munch, conductor of the Boston Symphony, lead the orchestra in a special concert for physicians and their families.

ORGANIZATION SECTION

PRESIDENT'S MID-YEAR REPORT

Since we last met in June at Atlantic City, I have traveled nearly 30,000 miles and talked to scores of audiences as your President. It is my pleasure at this time to report on some of the things which have happened in our organization and some of the things I have seen and heard throughout the United States. In all of my talks and radio, television and press interviews during the past few months I have tried to prove worthy of the trust which this House of Delegates has placed in me. There is one basic truth I've tried to drive home repeatedly—that doctors take care of sick folks, period. I have told my audiences that medicine can become a racket if other considerations are put ahead of that one simple humanitarian service to which we are all pledged.

From personal observation around the country I am satisfied that we are making good progress in informing the public and the profession of our objectives. We have also attempted to show in tangible ways the seriousness of our purpose. We must now intensify our educational program and increase our list of tangible accomplishments for the health benefit of the public. Complacency should be regarded as our greatest enemy. It would be presumptuous of me to attempt a detailed report of the many worthwhile activities engaged in by the various councils, committees and departments of your American Medical Association. These reports were splendidly presented in the Oct. 29 issue of THE JOURNAL on pages 878 to 947. I regret only that I do not have the power to make this "Officers Reports" section compulsory reading for every physician member in the United States. Here are the answers to the countless questions they have about "what is the A. M. A. doing?" It is inexcusable for the membership to be uninformed when the material is handed to them virtually on a silver platter.

For example, I would like to highlight some of the work being done by the Law Department, which was created in August, 1954, as a successor to the Bureau of Legal Medicine and Legislation. An effective liaison has been established between the department and the various councils and committees so that legal assistance is available on a day-to-day basis. Two very important studies have been launched by the department. One is to ascertain which states have established panels of experts to provide medical testimony in personal injury cases and in suits involving professional liability. The other is an extensive survey dealing with professional liability. During the month of October, the department sponsored, in cooperation with the Committee on Medicolegal Problems, three highly successful Medicolegal Symposiums in Chicago, Omaha and New York City. These meetings were attended by both physicians and attorneys. It is hoped that similar meetings can be arranged in the future in cooperation with the American Bar Association. Having attended the Chicago symposium, I might say that I am convinced such joint meetings will be most effective in promoting harmony between the two professions and assuring the proper administration of justice in medicolegal cases.

Let's, for a moment, look at the Council on Medical Service. As a past member and chairman I have a more intimate knowledge of its activities. Currently the group is engaged in upwards of 60 different projects. In the past few months it has given individual service to more than 3,700 physicians, communities, civic organizations and firms through its Physician Placement Program, in cooperation with 39 state medical associations. During the same period, the Council completed a review of the Hospital Construction Act, organized a Committee on Geriatrics, formulated guides on indigent care plans in cooperation with other groups, drew up principles for evaluating management and union health centers, surveyed physician attitudes on voluntary health insurance programs and prepared 10 new publications.

At a meeting in Chicago a couple of weeks ago, the Council on Mental Health brought together representatives of more than 40 state medical associations for a discussion of ways to improve the care of those unfortunates who are affected by mental and emotional disturbances. The activities of this Council are growing rapidly and are now bearing fruit. Along with the American Psychiatric Association the Council on Mental Health spearheaded development of the recently formed Joint Commission on Mental Illness and Health. This Commission will carry out a nationwide analysis and reevaluation of the human and economic problems of mental illness and health. Twenty other national organizations are joined in the work of the Commission. Time will not permit me to even touch on the invaluable work of our Council on Medical Education and Hospitals, the Division of Councils of Therapy and Research, the Bureau of Health Education, the Department of Public Relations, the Council on Scientific Exhibits, and the many other groups within our setup, but we owe each and every one of them a rousing vote of thanks for devoted performance of duty.

Yes, we are moving along in the right direction. But before we can successfully achieve the objectives we proclaim to the public, we have to deal with some critical problems affecting internal relationships in the field of medicine. Uppermost is the situation existing between some of the hospitals and the anesthesiologists, radiologists and pathologists. I cannot go into detail on specific instances because there are peculiar local circumstances to be considered in each case. However, I have found that where serious differences of opinion exist between hospital administrators and the specialists I have listed, stubbornness and lack of understanding create the roadblocks that cut off amicable solution.
